603784

NATURE

A WEEKLY

ILLUSTRATED JOURNAL OF SCIENCE

LONDON
R. CLAY, SONS, AND TAYLOR, PRINTERS,
BREAD STREET HILL, QUEEN VICTORIA STREET

INDEX

AACH, the, and the Danube, 233
Abercromby (Hon. Ralph), the *Eurydice* Squall, 466
Abney (W. de W., F.R.S.), "A Treatise on Photography," 378; the Acceleration of Oxidation caused by the Least Refrangible End of the Spectrum, 518
Absolute Pitch, Lord Rayleigh, F.R.S., 12
Ackroyd (W.), on the Telephone, 330
Acoustic Repulsion, 515
Acoustical Effects of Atmospheric Pressure, G. Rayleigh Vicars, 244
Adulteration: in Berlin, 91; Anti-Adulteration Society at Leipzig, 91
Æolian Harps, 33
Africa: H. M. Stanley's Exploration of, 17, 49, 90, 193, 270, 297; International African Exploration Society, 71, 346; French Exploration of, 91; Italian Expedition to, 132; Exploration of Lake Albert Nyanza, 192, 364; the Belgian Expedition to, 193, 346, 467; Dr. Hildebrandt's Expedition, 194; Herr Gerhard Rohlf's Expedition to the Sahara, 211; the Marquis Antinori's Expedition, 211, 249; an Early African Explorer, 270; Mr. Stanley in England, 270; D'Anvers' History of North African Discovery, 280; Proposed Language Map of, 293; Herr Schütt's Expedition, 308; Prof. Oliver's "Flora of Tropical Africa," 319; German Exploration of, 324; Mr. Stanley's New Work on, 364; Exploration of South-West Africa, 364; African Dwarfs, 364; Proposed New Expedition, 383; Ancient Maps of Central Africa, 383; Dr. Effendi's Expedition, 408; the Lake Nyassa Region, 435; Exploration of Angola, 453; Dr. Bastian on African Weapons, 455; Trollope's "South Africa," 463; Church Missionary Society Expedition, 467; Exploration of, 279, 383, 468; Geographical Notes, 489; New Map of, 489; French Expedition to, 508
Agassiz (Alex.), North American Starfishes, 98; Cruise in the Gulf of Mexico, 151, 192, 454
Agriculture, Henderson's Manual of, 280
Agricultural Society, the Royal, 301
Air-Pump, Improvement of the, 310
Aitken (John), on a Means for Converting the Heat Motion possessed by Matter at Normal Temperature into Work, 260
Aix-la-Chapelle, the Polytechnic at 335
Albert (Herr Josef), Photography of Natural Colours, 92
Albert Nyanza, Exploration of, 364
Aldebaran, New Companion to, 488
Algæ, Green, 289
Algæ of the White Sea, 345
Algebra and Chemistry, Prof. J. J. Sylvester, F.R.S., 284, 309
Algeria, Proposed Schools in, 393
Allen (J. A.), on the American Bison, 127
Alloys of Tin, &c., Hardening of, 311
Alluard's New Condensing Hygrometer, 14, 28
Alpine Club, German, 468
Amber, Production of, 132
Amblyornis inornata, 110
America: American Journal of Science and Art, 18, 293; American Science, 18, 39, 113, 213, 293, 438, 497; American Association for the Advancement of Science, 37; American Bison, 127; American Philosophical Society, Proceedings of, 199; Entomology in, 222; American Naturalist, 232, 293; American Journal of Mathematics, 293; American Geographical Society, 346, 409; the Inland Fisheries, 382; American Longitudes, 408; American Geological Surveys, Prof. A. Geikie, F.R.S., 431; Bibliographical Index of North American Plants, 514. *See also* United States, New York, Philadelphia, &c.
Amines, Halogen, Derivatives of, 151
Amsterdam and St. Paul, the Islands of, Prof. E. Perceval Wright, 326
Analogies of Plant and Animal Life, Francis Darwin, 388, 411
Ancient History from the Monuments, George Smith, 119
Angara, Exploration of the, 308
Angola, Exploration of, 453
Animal and Plant Life, Analogies of, Francis Darwin, 388, 411
Animal Eggs, the Earliest Changes in, 509
Annalen der Physik und Chemie, 39, 214, 254, 294, 394
Annuaire Bureau des Longitudes of France, 211
Anthony (John G.), Death of, 39, 133
Anthropology: Anthropological Exhibition in Moscow, 16; Anthropological Institute, 76, 171, 176, 215, 315, 355, 415, 470, 499; Anthropological Literature, 1876, 133; Anthropologische Gesellschaft of Berlin, 438; Anthropology in Moscow, 171; of Central Asia, 172; Russian Collection at the Paris Exhibition, 350
Antibes, Thuret's Garden at, 351
Antimony, Atomic Weight of, 293, 439
Antinori (Marquis), Supposed Death of, 71, 110; his African Expedition, 110, 211, 249
Antiquity of Man, 315
Antiseptic Vapours, the Action of Certain, on the Ripening of Fruits, 150
Ants, the Habits of, Sir John Lubbock, F.R.S., 355; the Agricultural Ants of Texas, 433
Apiculture at the Paris Exhibition, 309
Apothecaries, Society of, Prizes in Botany, 109
Appunn and Kœnig—Beats in Confined Air, Alex. J. Ellis, F.R.S., 26
Aquatic Respiration, 290
Ararat, Prof. Bryce's, Prof. A. Geikie, F.R.S., 205
Archibald (E. D.), Indian Rainfall, 505
Archiv for Mathematik og Naturvidenskab, 172
Arctic Auroræ, J. Rand Capron, 162
Arctic Exploration: 132, 271, 290, 324, 408, 468; Prof. Nordenskjöld's Expedition, 90; Discovery of Arctic Fossil Plants, 115; the Howgate Expedition, 153
Arctic Fauna, 155
Arctic Map, the Zenis', 71
Artesian Well at Pesth, 109
Articulate Speech, Elements of, Dr. W. H. Corfield, 447
Artificial Flowers and Insects, 133, 162
Arthropods, Sound-producing, W. Saville Kent, 11; Origin of Tracheæ in, 284, 340
Ascidians, Deep Sea, 289
Asseline (M.), Death of, 490
Astronomy: Proctor's "Myths and Marvels of Astronomy," 180; Wolf's History of Astronomy, J. R. Hind, F.R.S., 259; English Translation of, J. R. Hind, F.R.S., 359; Astronomisches Jahrbuch, Berlin, 507; Our Astronomical Column, 14, 36, 46, 63, 82, 104, 129, 149, 163, 189, 209, 231, 247, 269, 288, 306, 323, 343, 363, 381, 407, 432, 452, 418, 507; Astronomical Society, *see* Royal
Atlantic Shells, Wollaston's, 503
"Atlas Céleste," Ch. Dien, 141
Atmospheric Movements, 307
Atmospheric Pressure of Europe, 15
Atmospheric Pressure, Acoustical Effects of, G. Rayleigh Vicars, 244

Aurora Australis, Spectrum of, Commander J. P. Maclear, 11
Aurora Borealis, Extent and Principal Zone of the, 373
Australia: C. H. Eden's "Fifth Continent with the Adjacent Islands," 121; Exploration of, 271; Meteorology of Western, 363; Bees in, 372; Australian Monotremata, E. P. Ramsay, 401
Austria: the Austrian Comet Medal, 129; Education in, 155; University Libraries of, 374
Autopsy, the Society of Mutual, 490
Avalanches in Styria, 273
Aveling (E. B.), Physiological Tables, 5
Azimuth Instrument, a New, 308

Babylonia, the Primitive Culture of, 415
Bacteria: Prof. J. Burdon Sanderson, F.R.S., 84; Prof. Tyndall on, 134; in Water, G. F. Dowdeswell, 323; in Oxygen, 393
Baker (J. G.), "The Flora of Mauritius and Seychelles," 77
Balfour (Prof.) Proposed Portrait of, 393
Balloon, the Tuileries Captive, 330, 454, 491; Balloons and Arctic Exploration, 171
Ballot (Dr. Buys), on the Mean Atmospheric Pressure of Europe, 15
Baltic and German Oceans, Physiography of, 411
Baltimore, Johns Hopkins University, Anniversary of, 459; Fellowships at, 517
Barkas (T. P.), the Daylight Meteor of March 25, 1878, 467
Barnard and Mayer, the Sources and Reflection of Light, 405, 427
Barometric Oscillation, 135
Barrett (Prof. W. F.), a Cheap Telephone, 193; New Form of Gasholder, 253; Early Electric Telephony, 510
Bary (Dr. Erwin von), Death of, 71
Baryta, Lime, and Strontium, Crystallisation of, 372
Bashforth (Rev. Francis), Trajectories of Shot, 401, 506
Batchelor's Patent Working Drawings—Trunk Engine, 160
Bathing-Place at Harrow School, Arthur G. Watson, 487
Beachbury, Earthquake at, 212
Becquerel (Antoine César), Obituary Notice of, 244
Beer, Adulteration of, 251
Bees killed by Tritoma, Alfred R. Wallace, 45; Bees and Flowers, John B. Bridgman, 102; and *Gentiana asclepiadea*, F. M. Burton, 201; Apiculture at the Paris Exhibition, 309; Australian Bees, 372, 411
Beetles of St. Helena, E. C. Rye, 338
Beiblatter zu den Annalen der Physik und Chemie, 39
Belgrand (M.), Death of, 473
Bell (Prof. Graham), on the Telephone, 135
Bell (I. Lowthian, F.R.S.), Separation of Phosphorus from Pig-iron, 459
Bell (Prof. T., F.R.S.), "White's Natural History of Selborne," 399
Bentham's "Flora Australiensis," 212
Bergen, proposed University at, 95
Berlin: Death of Pongo at the Aquarium, 70; Geographical Society of, 91, 194, 271, 409, 411; New Polytechnic at, 155; University Intelligence, 175, 214, 254; the University Library, 194; the Telegraphs in, 251; Academy of Science, 252; Arms and Weapons at the Royal Museum, 330; Anthropologische Gesellschaft, 350; "Commers" at, 393; Botanical Specimens in, 454
Berliner astronomisches Jahrbuch and the Minor Planets, 507
Bermudas, the Fauna of the, 18; Bermuda Lizard, G. Brown Goode, 425
Bern, University Statistics, 374
Bernard (Claude), Obituary Notice of, 304; Funeral of, 329; Monument to, 370, 409
Bessemer (Henry), Glass for Reflectors, 241
Bettany and Parker's "Morphology of the Skull," 3
Biggs-Wither (T. P.), "Pioneering in South Brazil," 423
Binary-Star Castor, the, 105
Biological Notes, 127, 221, 289, 344, 382, 433, 508
Birchall (Edwin), the Insects of Chili and New Zealand, 221, 260
Birds: the Protection of, in Germany, 251; Mimicry in, 361, 380, 438; Poaching, 509
Birkbeck Institution, 334, 393
Bismarck (Prince) and the Telephone, 91
Bison, the American, 127
Blackbirds, Exportation of, from Corsica, 309
Blakesley (J. H.), Phoneidoscopic Representation of Vowels and Dipthongs, 486
Bland (Thos.), Great Waterfalls, 361
Bleeker (Dr. P.), Obituary Notice of, 286; his "Atlas," 309
Blood Corpuscle, the Structure of, 20
Bolivia, Capt. Musters on, 90
Bonavia (Dr. E.), Contribution to the Sun-spot Theory of Rainfall, 61; Nocturnal Increase of Temperature with Elevation, 101
Bone, Transformation of Cartilage into, 345
Bonomi (Joseph), Death of, 370
Bonn, Prof. Kekulé's Address on Chemistry, 55
Booth (Rev. James, LL.D., F.R.S.), Death of, 513
Boracic Acid, Origin and Formation of, 150
Borneo, Volcanic Phenomenon in, A. H. Everett, 200
Bosanquet (J. Whatman), Death of, 212
Botanical Exchange Society at Buda-Pesth, 437
Botanical Specimens in Berlin, 454
Botany: in Germany, 158; Prizes in, for Young Women, 314
Boulders, Preservation of, in France, 391
Bournemouth, the Eocene Flora of, J. S. Gardner, 47; Fossil Hunting at, J. S. Gardner, 369; the Bournemouth Beds, 395
Brahe (Tycho), Star of 1572, 129
Brain of a Fossil Mammal, 222; Prof. O. C. Marsh on, 340
Brake, the Westinghouse, 410, 507
Brandeis (Dr. Richard C.), Philadelphia Diplomas, 221
Braun (Alex.), Sale of his Herbarium, 410
Brazil, Mr. H. H. Smith's Exploration of, 308
Brazil, Pioneering in South, T. P. Biggs-Wither, 423
Breaks, the Telephone as a Means of Measuring the Speed of High, J. E. H. Gordon, 424
Brehm (Dr. A. E.), Thierleben, "Die Saugethiere," 41
Breslau, University Statistics, 374
Bridgman (John B.), Bees and Flowers, 102
Brisbane, Hailstorm at, 455
Bristol: Museum and Library, 16; University College, 20, 134; Naturalists' Society, 193, 292, 311
British Archæological Association, 350
British Association, 1879 Meeting, 192, 232
British Channel Tunnel, 109
British Flora, the Future of our, A. Craig-Christie, 62
British Medical Association, Grants of the, 90
British Museum, the Salaries of the Officers in the, 197
Broun (J. Allan, F.R.S.), the Sun's Magnetic Action at the Present Time, 183; Sun-spots and Terrestrial Magnetism, 262, 280
Broun (Prof. W. Le Roy), Terrestrial Magnetism, 281
Browning's Absorption Bands Apparatus, 513
Brüggemann (Dr. F.), Death of, 473
Brunswick, New University Buildings at, 75
Brussels, the Royal Observatory, 288
Bryce (James, LL.D.), "Transcaucasia and Ararat," 25, 205
Bryozoa, the Shell of the, 355
Buchan (Alex.), Sun-spots and Rainfall, 505
Buda-Pesth, Centenary of the University, 195; Botanical Exchange Society at, 437
Buddhism, T. W. Rhys Davids, 239
Buchanan (J. Y.), Oxygen in Sea-Water, 162
Burbidge (F. W.), "Horticulture," 142
Burial-Ground, Discovery of a Prehistoric, near Berlin, 391
Burton (Capt.), Exploration of the Land of Midian, 53, 132
Burton (F. M.), Insects and Artificial Flowers, 162; *Gentiana asclepiadea* and Bees, 201
Bushman Drawings, Prof. G. Fritsch on, 350
Butterflies in Iceland, No, 243, 260
Byrne (Oliver), the Geometry of Compasses, 199
Byssus in the Mussel, 289

Cairo, Geographical Society, 468
Callao, Waterspouts in, 372
Calmy (Dr.), Eucalyptus, 283
Cambridge: University Intelligence, 39, 74, 95, 134, 154, 294, 393; Science at, 39; Philosophical Society, 96, 416; the Mathematical Tripos, 275; Science Exhibitions, 334; Woodwardian Geological Museum, 354; Report of the University Commission, 415; Report on the Teaching of the University, 497
Cameron (J.), Sound and Density, 507
C[illegible]da, Extraordinary Rain-storm in, 490
Cape of Good Hope Observatory, 269
Capello (Joas), Sun-spots and Terrestrial Magnetism, 488

Capron (J. Rand), Arctic Auroræ, 162; "Photographic Spectra," 259
Carbon of Plants, J. W. Moll's Researches on, 344
Carnac, Archæological Researches at, James Miln, 379
Carnivorous Plants, Francisco Ginez, 63
Carpenter (Dr. P. P.), his Collection of Shells, 513
Carpenter (Wm. B., F.R.S.), the Radiometer and its Lessons, 26, 61; Mr. Crookes and Eva Fay, 81, 101, 122
Carpmael (W.), Telephone Experiments, 342
Cartilage, Transformation of, into Bone, 345
Caspian, Prof. Grimm on the Fauna of the, 345
Cassell's Natural History, Vol. i, 365
Castleton, Local Museum at, 454
Castor, the Binary Star, 105
Caucasus, Prof. Abich's Work on the, 309
Causation of Sleep, 124
Cavendish (Henry), his Writings on Electricity, 75
Cazin (Prof.), Death of, 16
Cecil (Henry), Hearing and Smell in Insects, 102, 381; the Wasp and the Spider, 448
"Celestial Atlas," Dien's, 141
Cerf (Mdlle. Henrietta), Death of, 71
Cesnola (Gen. L. Palma di), "Cyprus," 397
Chadwick Museum, 272
Challenger, the, Estimates of the Volume of the Gulf Stream, T. Mellard Reade, 144; in the Atlantic, Sir Wyville Thomson's Account of, 145, 185; Laboratory Experiences on the, 394
Channel Islands, a Zoological Station for the, W. Saville Kent, 102, 475
Chappell (Wm., F.S.A.), Music a Science of Numbers, 32
Charkow, University of, 195
Charnwood Forest, the Rocks of, 294
Cheeseman (T. F.), Fertilisation of *Glossostigma*, 163
Cheijan (Omer), Translation of the Poems of, 351
Chemistry: Chemical Society, 40, 75, 134, 215, 255, 315, 394, 439, 499, 519; the Research Fund, 291, 309, 454; Anniversary Meeting of the Society, 479; a Problem in Chemical Affinity, 151; Chemical Notes, 150, 269; Die chemische Industrie, 251; Fowne's Manual of, 24; Prof. Kekulé on the Position of, 55; N. N. Lubavin on Physical Chemistry, 240; Institute of, 291, 309; Chemistry and Algebra, Prof. J. J. Sylvester, F.R.S., 284, 309; Frankland's Researches in, Prof. J. Emerson Reynolds, 318; Dictionaries of, 455, 514
Chester Society of Natural Sciences, 16
Chili: Insect-Fauna of, R. McLachlan, F.R.S., 162; A. R. Wallace, 182; the Insects of Chili and New Zealand, 221, 260
Chimpanzee at the Westminster Aquarium, 153
China: Telegraphy in, 310; Exploration of, 346; the Telephone in, 392; Mr. Baber's Report of the Grosvenor Mission, 434; Geographical Notes, 452; Chinese Remedy for *Cynanche tonsillaris*, 475; "Gray's China," 484; Chinese Plants and Animals in Paris, 513
Chloride of Silver Battery, Dr. De la Rue's Researches on the Electric Discharge with, 214
Chronometers, Trial of German and Swiss, 409
Cinchona, Cultivation of, 410
Cissbury: Exploration of the Cave-Pits, 53, 171, 215, 409
Clark (Xenos), Singing in the Ears, 342
Cleopatra's Needle, 251
Cliff-Dwellers in the United States, 409
Climatology: of the Spanish Peninsula, 248; of the Fiji Islands, 248; of India, 307; of English Sea-side Resorts, 356
Clock, a Watchman-Controlling, 292
Clusters and Nebulæ, Literature of the, 288
Cobalt and Nickel, Iodates of, 150
Cochin China, the French Colony in, 492
Coggia's Comet, 497
Cohesion Figures in Liquids, Diffusion of, 124
Cole (Alan S.), State Aid to Music, 474
"Coleoptera Sanctæ-Helenæ," Wollaston's, 338
Colley (Prof. R.), Electrical Experiment, 282
Collieries, Telegraphic Warnings in, 16
Colonies, Exploring, 290
Colorado, Atlas of, 371
Colours, Comparison of the Intensity of Light of Various, 438
Colour Sense of the Greeks, Prof. W. Robertson Smith, 100
Columbus, the Burial-place of, 17
Comets: De Vico's, 15; of Short Period of 1878, 36; of 1873, 46; the Comet of 1672, 63; the Austrian Comet-Medal, 129; Donati's Comet of 1858, 149; the Comet 1106, 189; the Comets of 1618, 247; the Periodical Comet 1873, 344; Tempel's Comet of Short Period, 408; Coggia's Comet, 497; Encke's Comet in 1878, 507
Compass Adjustment in Iron Ships, Sir William Thomson, F.R.S., 331, 352, 387
Compasses, the Geometry of, Oliver Byrne, 199
Congo, the Yallala Rapids on the, 62
Connaissance des Temps for 1879, 70
Conrad (Timothy Abbott), Death of, 39
Conservation of Energy, Lecture Experiment, W. A. Shenstone, 45
Cooke (C. J.), Landslips near Cork, 425
Cooke (Conrad W.) Cumulative Temperatures, 322, 448, 486
Cooling Powers of Various Liquids, 132
Cooper (Robt.) Mr. Crookes and Eva Fay, 183
Copeland (Ralph), Meteor, 29
Corbett (Dr. Joseph Henry), Death of, 410
Cordoba Observatory, 83, 209
Corfield (Dr. W. H.), Elements of Articulate Speech, 447
Cork, Landslip near, C. J. Cooke, 425
Corpse, Spasms in a Guillotined, 437
Corsica, Exportation of Blackbirds from, 309
Coryphodon, Brain of a Fossil Species of, 222
"Cotton Goods, the Sizing of," Thomson, 4
Cotton (Dr. R. P.), his Collection of Ilford Fossils, 231
Crabs, Horse-Shoe, 289
Craig-Christie (A.), the Future of our British Flora, 62
Crawfish, Artificial Culture of, 133
Cremmen, Discovery of a Prehistoric Burial Ground near, 301
Croll (Dr. James, F.R.S.), Age of the Sun in Relation to Evolution, 206, 321, 464
Crookes (William, F.R.S.), the Radiometer and its Lessons, 7, 43; and Eva Fay, 81, 101, 122, 183, 200
Cruelty to Animals' Act and Physiological Teaching, Frank W. Young, 45
Crustaceans, Classification of Decapod, 127
Cryptogams, Hofmeister's work on, 344; Cryptogamic Society of Scotland, 133; Cryptogamic Society of Italy, 491
Cumberland Association of Literature and Science, 133
Cumulative Temperatures, 308, 322, 448, 486
Curious Phenomenon, 10
Cyanide of Gold, Double Salts with, 151
Cycadeæ, Structure of, 222
Cyclones and Anti-Cyclones, 134
Cynanche tonsillaris, Chinese Remedy for, 475
"Cyprus," General L. Palma di Cesnola, 397

D'Albertis' and Beccari's Voyage Round the World, 53
D'Albertis' Exploration of New Guinea, 383
Danish Greenland, Dr. Henry Rink, 57
D'Anvers (N.), "History of North African Discovery," 280
Danube, the, and the Aach, 233
D'Arrest's Spectroscopical Researches, 311
Darwin (Charles, F.R.S.), Conferring an Honorary Degree on at Cambridge, 52, 64; Fritz Müller on Flowers and Insects, 78; Proposed Memorial to, 95, 350; "Different Forms of Flowers," 445
Darwin (Francis), Insectivorous Plants, 222; Analogies of Plant and Animal Life, 388, 411
Darwin (G. H.), Geological Time, 509
Davids (T. W. Rhys), Buddhism, 239
Davyum, Sergius Kern, 245, 292
Dawson (G. M.), Drowned by a Devil Fish, 282
Deaf and Dumb Language, 479
Decapod Crustaceans, Classification of, 127
Declination Ranges and Sun-spots, Prof. Balfour Stewart, F.R.S., 326
Deep-Sea Ascidians, 289
Deer, Prof. Boyd Dawkins on the, of the Miocene and Pliocene Strata, 255
De la Rue's Diaries and Calendars, 11
De la Rue (Warren, F.R.S.), Researches on the Electric Discharge with the Chloride of Silver Battery, 214
Dendritic Gold, 283
Denning (W. F.), Meteor of October 19, 1877, 10; Shooting Stars, 201
Density and Sound, J. Cameron, 507
Development in Plants, the First Stages of, 433

De Vico's Comet of Short Period, 15
Devil Fish, Drowned by a, 27, 282
Dien's "Celestial Atlas," 141
Diet, A Physician's Experiment, 305
Diffusion Figures in Liquids, 87, 102, 124
Diffusion of Gases, 92
Digital Reduction, the Laws of, 128
Digits, Hereditary Case of Six, 372
Dimetian and Pebidian Rocks of Pembrokeshire, 155
Dispersal, Means of, W. L. Distant, 124
Distant (W. L.), Means of Dispersal, 124; Oriental Affinities in the Ethiopian Insect Fauna, 282
Distillation of Organic Liquids by Means of Steam, 270
Dixon (Charles), Towering of Wounded Birds, 45
Doberck (Dr. W.), Ole Römer, 105
Dog-Fish, Capture of a, 251
Dohrn (Dr. Anton), the Zoological Station, Naples, 329, 360
Donati's Comet of 1858, 149
Donisthorpe (Wordsworth), Change of Habits in Toads, 242
Dorpat, University Intelligence, 354
Dorset, Earthquake in, 38
Double Salts with Cyanide of Gold, 151
Double Stars, 407
Dowdeswell (G. F), Bacteria in Water, 323
Downing (A. W.), Sun-spots and Terrestrial Magnetism, 242
Draper (Dr. Henry), Oxygen in the Sun, 339
Dresden, the Polytechnic, 354
Drosera rotundifolia, the Nutrition of, 222
Drought in the Southern Hemisphere, 436, 447, 454
Drury's "Chronology at a Glance," 253
Dublin, the Royal Society, 46
Dumas' Lectures on Chemical Philosophy, 193
Duncan (Dr. P. Martin), Cassell's Natural History, 365
Dundee Naturalists' Society, 54
Dun Echt Observatory Publications, 432
Dust, Explosive, 283
Dwarfs, African, 364
Dyer (Prof. W. T. Thiselton), the Rain-Tree of Moyobamba, 349

Early Man, Traces of, in Japan, 89
Ears, Singing in the, Xenos Clark, 342
Earth, Age of the, W. M. Flinders Petrie, 465
Earthquakes, 330; at Lisbon, 17; in Dorset, 38; New York, 38; at Iquique, 90; in Canada, 90, 110; in Nebraska, 110; the "Ionia Volcano," 110; at Beachburg, 212; in Jersey, 272; of January 28, 1878, 292; at Liesthal, 475; at St. Stefano, 514
Earthquakes and Seiches, Dr. F. A. Forel, 281
Earthworm in Relation to the Fertility of the Ground, 18, 28, 62
Earthworm, Supposed Gigantic, 325
Earwigs, 128
Easter, the Date of, 433
Eastern Excavations, 397
Eclipse Photography, the Use of the Reflection Grating in, J. Norman Lockyer, F.R.S., 354
Eclipses: Solar of February 2, 1878, 36; Total Solar Eclipse of A.D. 418, 163; the Total Solar Eclipse of July 29, 1878, 250, 269, 381, 452, 453; the Coming Total Solar Eclipse, J. Norman Lockyer, F.R.S., 481, 501

NATURE

A WEEKLY ILLUSTRATED JOURNAL OF SCIENCE

"To the solid grouna
Of Nature trusts the mind which builds for aye."—WORDSWORTH

THURSDAY, NOVEMBER 1, 1877

THE SUN'S DISTANCE

A MOST interesting state paper has just been issued; we refer to the Report by the Astronomer-Royal on the Telescopic Observations of the Transit of Venus of 1874, made by the Expeditions sent out by the British Government and the results deduced from them. The Astronomer-Royal suggests that another report may be called for when the photographs of the transit have been completely measured and worked out, if possible in combination with the results of similar observations made in the expeditions organised by other governments.

It will be seen from the present Report that the plan of operations actually pursued has been very nearly that proposed by the Astronomer-Royal in his communication to the Royal Astronomical Society on December 11, 1868, when for the third time directing attention to the arrangements which it would be necessary to make for the efficient observation of the transits of 1874 and 1882. The method of absolute longitudes was to be applied for observations both of ingress and egress; it being therefore essential that the longitudes of the observing-stations should be determined with precision; and the longitudes recommended to be fixed by Great Britain were Alexandria, stations in New Zealand and in the Sandwich Islands, Kerguelen's Land, and Mauritius or the two islands of Rodriguez and Bourbon.

The stations eventually selected for observations by the British expedition were fixed upon "entirely by consideration of the influence which their positions would have in determining with accuracy the necessary alteration of parallax." They were: Egypt, the Sandwich Islands, the Island of Rodriguez, New Zealand, and Kerguelen's Land. It was intended to adopt in each of these districts one fundamental station, the longitude of which was to be independently determined, for conversion of local times into Greenwich times, and subordinate to this primary station, other stations were proposed to be selected at such distances that advantage might be taken of different states of weather that might possibly prevail.

In Egypt his Highness the Khedive rendered every possible assistance, tents being supplied with military guards for the protection of the observers and their instruments, and telegraph wires erected. The Astronomer-Royal acknowledges the obligations of the expedition to the liberality of the Eastern Telegraph Company, in affording the means of determining with extreme accuracy and great facility the longitude of the principal station Mokattam. Greenwich was easily connected with Porth Curno, in Cornwall, whence there is an uninterrupted line to Alexandria, the longest submarine line in the world; Alexandria was connected with Mokattam by aid of the special line constructed by the Khedive from Cairo to the station. It is further stated that time-communication was also made from Mokattam through Cairo to Thebes, and to Suez by the ordinary telegraph, Thebes and Suez being the other Egyptian stations where the transit was observed.

In the Sandwich Islands much assistance was received from King Kalakaua and members of the reigning family. The principal station was at Honolulu, the longitude of which was determined partly by meridian-transits of the moon and partly by transits of the moon observed with the Altazimuth instrument. Waimea, in the island Kauai, where observers were also placed, was connected with Honolulu by means of chronometers carried in H.M.S. *Tercdos*. At the Island of Rodriguez the longitudes were determined in the same manner as for the Sandwich Islands stations, for three positions, viz., Point Venus, the Hermitage, and Point Coton; and communication was further made with the Mauritius and with Lord Lindsay's expedition with the aid of H.M.S *Shearwater*, the preliminary results being stated by Sir George Airy to agree closely with those given by the lunar observations. At Kerguelen's Land, again, the operations were similar; Supply Bay and Thumb Peak being the stations chosen.

In New Zealand unfavourable weather much interfered with the observations, and Sir George Airy had at first been led to suppose that all useful observation had been lost; it subsequently appeared, however, that this was not the case, one phase of the transit being well seen at Burnham, the longitude of which was fixed by meridian transits of the moon.

The Report is divided into three sections or tables.

In the first are given the descriptions of the various phenomena, in the words of the observers, with the Greenwich sidereal times of the different phases, obtained from accurate reduction of the observations for longitude here particularised; where such longitudes depend upon lunar observations the places of the *Nautical Almanac* were carefully corrected by observations on nearly the same days at Greenwich, Paris, Strasburg, and Königsberg. In studying these original descriptions, Sir George Airy was led to infer that it was "possible to fix upon three distinct phases for the *Ingress* and four for the *Egress*," though it might have been supposed that Egress and Ingress would exhibit the same number of distinct phases in inverse order; this was not the case in practice. The first phase, α, utilised in the calculations is the appearance of the planet just within the sun's disc, but the light between the two limbs being very obscure. After an interval of about twenty seconds "the light begins to clear, and the observers generally think that the contact is passed;" this is phase β. About twenty seconds later, the light which at phase β was not equal to that of the sun's limb, is free from all shadow, and the phase is called γ. Sir George Airy finds that of these phases β is the most exact, observers, even in the presence of clouds of moderate density, agreeing within three or four seconds, though for other phases much greater discordances are exhibited. Similarly at the Egress, the first appearance of a fine line or faint shadow is called δ, this becoming definite, or a "brown haze" appearing, is called ϵ. When most observers record "contact," the shadow having reached a maximum intensity, the phase is called ζ, and in this phase there is an agreement amongst observers, much closer than in other phases at Egress. The "circular" contact at Egress is called η.

In the second section of the Report, or Table II., these "adopted phases are massed for each district in which the parallax-factor is nearly identical," and several of the details of reduction are included. With the longitudes determined as above, the recorded times of the various phases of the transit were converted into Greenwich sidereal times. With the calculated apparent places of the sun and Venus in the *Nautical Almanac*, as deduced from Leverrier's Tables, an ephemeris was prepared exhibiting the predicted geocentric places for every tenth second of Greenwich sidereal time throughout the transit, and from these numbers the apparent positions of sun and planet at each station were computed. Calculations were further made, showing how the predicted places would be affected by alteration of the local longitude, by change in the tabular places of the sun and Venus, and by alteration of their tabular parallaxes; the first two alterations were not essential in these reductions, but the determination of alterations of the third class, as it is remarked, constituted "the special object of the expedition." The form of the reductions was "entirely determined by the consideration that such alterations must be made in the parallaxes as will render the observations of the same phenomena in different parts of the earth consistent with each other." In Table III. we have "the mean solar parallax deduced from every available combination." Thus Ingress accelerated at the Sandwich Islands is compared with Ingress retarded at Rodriguez and with Ingress retarded at Kerguelen's Land; Egress retarded at Mokattam and Suez with Egress retarded at Rodriguez, and likewise with Egress accelerated at the two stations in Kerguelen's; and again the retarded Egress at Thebes is compared with Egress retarded at Rodriguez and with Egress accelerated at Kerguelen's. The greatest separate value of the solar parallax resulting from these different comparisons is 8″·933 and the least 8″·407. Weights are given to the various determinations depending, firstly, upon the number of observations and the magnitude of the parallax-factor; and secondly, upon the particular phase α, β, γ, δ, ϵ, and ζ being included. Thus it is found that all the combinations for *Ingress* give the mean solar parallax 8″·739, weight 10·46, and all the combinations for *Egress* give 8″·847, weight 2·53, whence the general result is 8″·760, from which Sir George Airy finds the mean distance of the sun equal to 93,300,000 miles. The New Zealand observations were not included in these calculations; their mean result is 8″·764, almost identical with the above. It is remarked that many persons may perhaps consider that the more closely-agreeing phases β and ζ should be employed in deducing the value of the parallax to the exclusion of the others. If this be done we shall have from the *Ingress* 8″·748, and from the *Egress* 8″·905, or with their due weights a mean value 8″·773.

In this outline of the details contained in the Astronomer-Royal's first Report upon the observations of the transit of Venus, and the conclusions to be drawn from them we have adhered closely to his own words. Pending the appearance of the deductions to be made from the complete measuring of the photographs, the results before us are perhaps to be regarded as provisional ones only, or we have not yet learned all that may be done from the work of the British expeditions, so laboriously organised by Sir George Airy. Many astronomers we can imagine will regard with some suspicion so small a parallax as 8″·76, which is a tenth of a second less than has been given by the most reliable previous investigations, upon different principles. In illustration we may quote the separate results from which Prof. Newcomb obtained his value of the parallax, now adopted in most of our ephemerides:—

	″
From meridian observations of Mars, 1862	8·855
From micrometric observations of Mars, 1862 ...	8·842
From parallactic inequality of the moon	8·838
From the lunar equation of the earth	8·809
From the transit of Venus, 1769 (Powalky's reduction)	8·860
From Foucault's experiments on light	8·860

To these may be added Leverrier's value subsequently deduced from the planetary theories, which is also 8″·86. Newcomb's mean figure, taking account of weights corresponding to the probable errors is 8″·848, which, with Capt. Clarke's measure of the earth's equator, implies that the mean distance of the sun is 92,393,000 miles. Sir George Airy's 8″·760 would similarly place the sun at a mean distance of 93,321,000 miles.

It is well known that some astronomers have not expected our knowledge of the sun's distance to be greatly improved from the observations of the transit of Venus, regarding such an opportunity as is presented by a close opposition of Mars as affording at least as favourable conditions, and the result of Mr. Gill's expedition to

Ascension to utilise the late opposition will be on this account awaited with much interest. Nevertheless, whatever degree of opinion might be entertained by competent authorities, it appears to have been felt by those immediately responsible for action, in different civilised nations where science is encouraged, that so rare a phenomenon as a transit of Venus could not be allowed to pass without every exertion being made to utilise it, and this country may lay claim to an honourable share in the great scientific effort, thanks mainly to the long-continued and admirably-directed endeavours of the Astronomer-Royal to secure this result.

Several of the stations occupied during the transit of 1874 will be available for the transit of 1882, Kerguelen's Land in particular, where at Ingress the sun will be at an elevation of 12°, the factor of parallax being 0·98. In that year there will also be the advantage of observations along the whole Atlantic sea-board of the United States and Canada, where, as pointed out by the Astronomer-Royal in 1868, the lowest factor is 0·95, and the smallest altitude of the sun 12° for observing the retarded Ingress; and for observing the Egress as accelerated by parallax, the factors are about 0·85, the sun's elevation varying from 4° at Halifax, to 32° at New Orleans, or Jamaica. Australian and New Zealand stations are important for retarded Egress.

As is well known, the transit of Venus on December 6, 1882, will be partly visible in this country.

PARKER AND BETTANY'S "MORPHOLOGY OF THE SKULL"

The Morphology of the Skull. By W. K. Parker, F.R.S., and G. T. Bettany, M.A. (London: Macmillan and Co., 1877.)

IN the minds of most of those who have paid no special attention to the subject the skull is regarded as a bony case formed to contain the brain, together with the face. There is also a constancy in the number and position of these bones which lead to the apparently necessary conclusion that occipital, sphenoid, parietal, and other elements are fundamental cranial structures; so that an exhaustive study of their relationships and variations might be thought entirely to cover the subject of skull structure.

That such is not the case has dawned upon us since the elaborate researches of Rathke and other able embryologists, among the foremost of whom must be placed Profs. Huxley and Gegenbauer, who have been followed by Mr. Parker, the author of the work under consideration, who on account of his peculiar aptitude for manipulation, his untiring zeal and his immense experience, has placed the subject of cranial morphology upon a footing infinitely more satisfactory than it has previously been. His numerous memoirs in the *Transactions* of the Royal, Zoological, and Linnean Societies form a mine of biological facts, so beautifully supplemented by their accompanying illustrations. The perusal of them all, in their proper sequence, is however a task only to be undertaken by the specialist, and it is on this account that we have no small degree of pleasure in being able to give a notice of "The Morphology of the Skull," a work of less than four hundred pages, in which is collected, condensed, and digested the mass of information spread through the larger memoirs.

The work consists of a series of chapters on the skulls of carefully-selected types of the five classes of the Vertebrata. Those chosen are:—

1. The Dog-fish and Skate
2. The Salmon.
3. The Axolotl.
4. The Frog.
5. The Common Snake.
6. The Fowl.
7. The Pig.

These are each described in all stages from their earliest appearance in the blastoderm to their adult condition. Following each chapter is a brief *résumé* of the peculiarities which have been observed in other members of each group, in such a manner that the student of any particular form can learn almost all he may require with reference to any special member of the sub-kingdom.

The primitive trabeculæ cranii, together with the parachordal cartilages and the branchial arches are traced from their earliest development until ossification in and around them has reached the limits of the different types. The insufficiency of our data for the determination of the cranial segments is prominently brought forward, although the moniliform constrictions of the anterior extremity of the notochord in the fowl and in the urodeles is stated, and thought to suggest a segmentation. On the subject of the vertebral theory of the bony skull, Mr. Parker tells us that "only one bony segment, the occipital, can be said to be clearly manifest in the skulls of fishes and amphibians. And in these forms there are no good grounds for assigning to the cranial bones special names indicating a correspondence to particular parts of vertebræ. From the study of adult structures in the mammalian groups skull-theories have been devised, lacking the basis of embryology; and granting that they express some of the truth respecting the highest forms of skull, there is only injury to knowledge in arbitrarily interpreting the lower forms by them. In reptiles the skull becomes much more perfect, but with wide variations in the different groups, such that they cannot be merely subordinated to and explained by the mammalian type. A careful study of the growth of the bird's skull, again, will show that it is impossible to express its composition on a simple formula derived from vertebral structures. But from the lower to the higher forms of vertebrates we can discern a growing away from the primordial type of skull towards and into a loftier development." This result of the extensive investigation upon which it is based is somewhat paradoxical. The "loftier development" of the highest types results in a skull some of whose components may be compared in detail with some expression of truth to vertebræ, whilst in the lower forms a similar comparison cannot be said to hold. And yet true vertebræ themselves, fully developed as far as their essential details are concerned, are found in forms far from high in the scale.

Mr. Parker's invaluable investigations besides their importance in a comparative anatomical point of view, have done much to demonstrate the degree of stress which must be laid on facts of cranial structure in problems relating to classification. His labours have led him to elaborate the instructive classification of birds promulgated by Prof. Huxley in 1867, and so to bring out many points of special interest in avian cranial osteology, demonstrating most clearly the principle which may be arrived at from the study of any special organ or single structure, that a fact which is of the greatest significance in determining the relationships of some one collection of species or genera, may be valueless in attempting to classify others. As an instance of this we may take the skull of the woodpeckers and wrynecks, the peculiarities of which have led Mr. Parker to place them in a division by themselves of primary importance, whereas there is nothing more certain than that their differences from the Toucans and Capitonidæ are only just sufficient to separate them as a family from either. And yet among almost all other orders of birds the cranial structure is invaluable in the determination of their affinities.

The uniformity of the nomenclature and the absence of any laxity in the expression of the mutual relations of parts, greatly increases the facility with which the great number of facts brought forward by the authors can be grasped, and no doubt it is Mr. Bettany whom we have in great measure to thank for the general selection and classification of those which have been chosen to form "The Morphology of the Skull."

In conclusion we feel certain that all who read the work under consideration, the very nature of which makes it almost impossible for us to discuss the details with reference to any of the points which it brings forward, will realise how important an addition it is to biological science, and no thinking student will lay it down without recognising how much scope there is for still further investigation in the same field, especially in that direction which leads to the explanation of the reason why cartilages grow and bones form in certain definite directions and situations and in them alone; in other words, the next book of the kind required is one on the dynamics of the development of the skull.

THOMSON'S "SIZING OF COTTON GOODS"

The Sizing of Cotton Goods. By Wm. Thomson. (Manchester: Palmer and Howe.)

IN weaving cotton cloth it is necessary that the warp, which has to withstand a considerable strain in the process of manufacture, should be artificially strengthened by "sizing," that is, by dressing the thread with some adhesive material so as to enable it to resist the pulling and wearing action of the healds and shuttle. In the earlier days of cotton manufacture the weaver contented himself with the use of a mixture of flour-paste and tallow; the first ingredient gave the thread the desired extra strength, the second removed the harshness which the use of flour alone would have given. But the manufacturer soon discovered that by a judicious selection of the components of his "size," and by alterations in the mode of applying it, he could confer upon the cloth the appearance of being fuller and stouter than it actually was, judging from the amount of cotton contained in it. The great scarcity of the raw material during the cotton famine which sprung out of the American civil war had a powerful effect in developing the ingenuity of a certain set of manufacturers, and there is no doubt that their machinations have had a lasting influence upon the mode of manufacture of grey cloth. As the weight of a piece of calico is one of the chief elements in determining its value, attempts were quickly made to increase that weight by mixing such bodies as powdered heavy-spar, or, worse still, of deliquescent salts like the chlorides of magnesium and calcium, with the sizing material. Occasionally the manufacturer in thus attempting to palm off water or a worthless mineral in lieu of good cotton over-reached himself and a just retribution overtook him in the shape of heavy damages for mildewed or rotten goods.

The results of many of these attempts afford excellent illustrations of the proverbial danger of a little knowledge; the manufacturer somehow acquired the information that chloride of calcium, an almost worthless bye-product in many chemical operations, was an excellent absorbent of atmospheric moisture; its advantages as an ingredient of the sizing mixture were therefore obvious; unfortunately he knew nothing of *oidium oranteacum* or *puccinia graminis*, and had probably never heard of *penicilium glaucum*, or he might have known that he was preparing a mixture specially suited to the development of these fungi. Silicate of soda or water-glass doubtless appeared at first sight to be an excellent substance for dressing warp, but a painful experience was needed to teach some manufacturers that these alkaline silicates rapidly absorb carbonic acid, and that the resultant products, namely, free silica, and sodium carbonate, together occupying a larger volume than the original silicate, exerted a disruptive action upon the hollow cotton-fibre and made the cloth rotten and useless. Mr. Thomson does not altogether shirk the consideration of the moral aspects of the question of sizing; he makes no secret of the fact that the operation is often done with fraudulent intention. He expresses his opinion distinctly enough that the introduction of an undue amount of size into goods intended for the home trade can serve no useful purpose, but we think he will find it difficult to convince ordinary or unbiased people that a composition consisting, to the extent of half its weight, of a mixture of putrid flour, or British gum, China clay, barytes, or magnesium chloride, tallow, or palm-oil, with a sufficient amount of chloride of zinc or carbolic acid to prevent the whole from running into absolute nastiness, is a fit material to clothe even the patient Hindoo or the prudent Chinaman. Mr. Thomson, however, takes this business of sizing as a fact which, of course, cannot be ignored, and he tries to make the best of it. In the outset he shows that, as it now stands, the process is one of the clumsiest, most unscientific, and least understood of all the operations with which the manufacturer has to deal, and he points out, clearly and concisely, wherein it is faulty, and how it may be amended.

The book is, of course, designed primarily for the use of grey-cloth manufacturers, calico-printers, and generally of those whose business it is to buy and sell calico; and the subject is mainly treated from the point of view of a chemist perfectly familiar with the objects sought to be gained by legitimate sizing. In plain and albeit scientific language he describes the various pieces of apparatus employed in ascertaining the value of the different ingredients in size; he points out the qualities, good and bad, of the materials employed to g[illegible] adhesive and softening qualities to the size; how the size is to be applied to the yarn; to what diseases or modes of decomposition it is liable; and how it may be preserved from mildew or mischievous changes. The book has every right to be regarded as the only important treatise on the subject which has yet appeared, and, as such, we would recommend it to all who are interested in the production of one of our chief staples. T.

OUR BOOK SHELF

Physiological Tables for the Use of Students. Compiled by Edward B. Aveling, D.Sc., F.L.S. (London: Hamilton, Adams, and Co.)

We are at a loss to find any excuse for the publication of these tables, which no one, we presume, would attempt to justify except on the plea that they may be useful in cramming students so as to pass the multifarious superficial examinations which are a blot upon our educational system.

They are unphilosophical in their plan, and altogether unreliable in their details. Some idea of the nature and value of the information which is here put up, as it were, into separate pigeon-holes for the use of the unwary, may be gathered from the following quotations. Nervous tissue, we are told, contains 15 per cent. of fats, thus classified:—

Fats, 15 per cent. in white, 5 per cent. in gray.	Oleo-phosphoric acid. Olein; margarin; palmitin. Cholesterin.

Would Dr. Aveling like to write a short essay upon oleo-phosphoric acid? Has he never heard of such bodies as glycerin-phosphoric acid and its derivative lecithin?

Or to quote from Table IV., where Dr. Aveling writes on the causes of the circulation:—

Causes of Circulation.	Impulse of heart.	
	Elasticity of arte-	
	Capillary Proofs.	Alterations in diameter of capillaries. Alterations of velocity of blood flowing through them Movement of blood after excision of heart in cold-blooded animals Emptying of arteries after death. Secretion after death First movement of blood in embryo towards, not from, the heart. Fœtus without heart has organs developed. Degeneration of heart during life without much alteration in the circulation. Heart working well, and yet circulation through some part ceases. Asphyxia.
	Muscular pres on veins	

Would it not be an admirable exercise to set the above lines to intending candidates in physiology and ask them to criticise them? Our readers will do so for themselves.

In the table referring to the sense organs we are confidently told that the nerve centres for the special sense of touch are the *thalami optici*, that the centres of the special sense of smell are the olfactory lobes, that the centres of sight are the corpora quadrigemina, the corpora geniculata, and the thalami optici.

But the above examples are more than sufficient to prove how dangerous a catalogue of mistakes Dr. Aveling has presented us with.

If science is to be used as a discipline in education, let it be fully and accurately taught; let us not imitate the old scholastic routine which forced unpalatable jargon in the form of "propria quæ maribus," &c., upon the unwilling student, and refuse to follow it in that which is its merit—its accuracy. A. G.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.]

Indium in British Blendes

It will be a matter of some interest to English mineralogists and chemists to know that certain blendes of Durham and, I believe, of Cumberland contain Indium in appreciable quantities. This fact has been made out by a very skilfully-conducted analysis by Dr. Flight in the laboratory attached to this department.

The work in the laboratory has, through the past two years, been almost exclusively devoted to the analysis of minerals selected from the division of the collection which is in process of being catalogued, and for which the crystallographic work has long been in progress.

When I gave the particular blendes in question to Dr. Flight for analysis, the grounds for their selection were that they were British, and that one of them in particular resembled certain foreign blendes which contain the rare metals found in association with this mineral.

The object of this letter is to secure a prompt announcement of Dr. Flight's having found Indium in the blende in question. He will in due time communicate further details of the analysis of the blende and of an elegant process by which he at once separates the Indium Sulphide from the blende.

NEVIL STORY MASKELYNE

Mineral Department, British Museum, October 30

The Radiometer and its Lessons

Will you allow me to make a few remarks in reply to to Dr. Carpenter's letter on "The Radiometer and its Lessons," published in the last number of NATURE, and to try to show that I had good grounds for the opinion I expressed at the late meeting of the British Association in reference to his article on the same subject in the *Nineteenth Century*.

Nearly the whole of the first three columns of Dr. Carpenter's letter is devoted to proving that he "was not influenced, when writing on the radiometer, by any *animus* arising from [his] personal antagonism to Mr. Crookes on another subject." As I never in any way charged him with being thus influenced, I do not think that this part of his letter calls for any further remark on my part than an expression of my sincere regret that it should have been possible for him to think that I intended to make such a charge.

Dr. Carpenter devotes the rest of his letter to showing that he had "adequate justification" for "making it appear that Mr. Crookes had put a wrong interpretation on his own results," and thus proves very conclusively that I had "adequate justification" for supposing it possible that he may have intended to make this appear in his article in the *Nineteenth Century*.

In order to make out his "justification," Dr. Carpenter sets himself to prove (1) that Mr. Crookes puts forward the "direct impact of the waves" as affording "a definite interpretation" of the motion of the radiometer, and (2) that he claimed "the discovery of a 'new force' or 'a new mode of force.'"

With regard to the first of these points, I think that few persons can have read or heard Mr. Crookes's accounts of his investigations without having observed how careful he was to reserve his judgment as to the cause of the remarkable effects he had discovered, and neither to give out as conclusive any explanation of his own, nor to adopt any of those suggested by others until, chiefly through his own further experiments, one of them had been shown to rest on sufficient evidence. It is true that on one occasion he uses the following words (quoted by Dr. Carpenter):—"My own impression is that the repulsion accompanying radiation is directly due to the impact of the waves on the surface of the moving mass, and not secondarily through the intervention of air-currents, electricity, or evaporation and condensation," and that, in several places in his earlier papers, he shows a leaning towards the same hypothesis; but this is a very different thing from having adopted this view as a "definite interpretation" of the phenomena. Even Dr. Carpenter does not attempt to show that Mr. Crookes ever, in so many words, committed himself to this theory, but concludes that he held it from considerations which, for fear of misrepresentation, I must give in Dr. Carpenter's own words :—

"After pointing out that 'there is no real difference between heat and light, all we can take account of [I presume he means physically, not physiologically] being difference of wave-length,' he [Mr. Crookes] thus continues : 'Take, for instance, a ray of definite refrangibility in the red. Falling on a thermometer it shows the action of *heat ;* on a thermopile it produces an *electric current ;* to the eye it appears as *light* and *colour ;* on a photographic plate it causes *chemical action ;* and on the suspended pith *it causes motion.*' Now (1) this motion being elsewhere spoken of as due to *the impetus given by a ray of light,* (2) a set of experiments being made to determine *the mechanical values of the different colours of the spectrum,* (3) an observation being recorded on *the weight of sunlight* (without the least intimation that he was 'speaking figuratively' as Mr. Crookes says

and (5) no hint whatever being given of the dependence of the result (as argued by Prof. Osborne Reynolds) on a 'heat-reaction' through the residual vapour, I still hold myself fully justified in attributing to Mr. Crookes the doctrine of the *direct mechanical action of light.*"

Taking these points in order and using Dr. Carpenter's numbers for reference, I may observe as to (1) that this seems to refer to Mr. Crookes's statement of an "impression" in a passage already quoted ; with regard to (2) that Mr. Crookes having found that "every ray from the ultra-red to the ultra-violet" produced a mechanical effect under the circumstances of his experiments, it was very natural that he should hope to get some clue as to the nature of the action by finding what rays produced the greatest effect ; of Dr. Carpenter's arguments (3), (4), and (5), it is difficult to speak with the seriousness befitting their author's many valuable services to the cause of science, and the "due consideration of . . . *his* and *my* relative positions." To conclude that Mr. Crookes must have held a particular theory from the fact that, when he had constructed an apparatus which spun round on exposure to light, he called it a "Light-mill ;" from his having neglected to give warning that he was "speaking figuratively" when he talked of "weighing a beam of sun-light," or from his having given no hint that he had adopted a rival theory, is certainly not to exemplify the "strict reasoning based on exact observation" which Dr. Carpenter recommends in the paragraph with which he concludes both his article and his letter to this Journal.

A few sentences before the passage I have quoted, Dr. Carpenter refers to the "whole phraseology" of Mr. Crookes's papers of January 5 and February 5, 1876, as indicating "that he *then* considered [the motion of the radiometer] as directly due to the impact of the waves upon the surface of the moving mass." This again seems to me a very unsound conclusion. The effect to the elucidation of which these papers were devoted was unquestionably due to the incident radiation, but whether as a primary or as a secondary effect, was still a matter for discussion. In my opinion the phraseology used in them implies no more than this : it indicates a relation of cause and effect, but, for the most part, leaves the question as to *how* the latter follows from the former, entirely untouched. If, however, Dr. Carpenter will refer to § 195 of the paper of February 5, as it is printed in the *Phil. Trans.* for 1876, he will see that Mr. Crookes did not *then* attribute the motion to *direct impact of the rays upon the surface* of the moving body, but rather to an elevation of its temperature, and a consequently increased *radiation of heat from its surface.* At the same time he will see that this suggestion is put forward in a tentative and entirely undogmatic way.

Dr. Carpenter next undertakes to show that Mr. Crookes laid claim to the discovery of a "new force" or a "new mode of force," finding his proof of this in a passage included in the quotation from his letter that I have given above. Commenting on this passage in the *Nineteenth Century* (p. 248), he says : "To the *three* attributes of radiation universally recognised by physicists, Mr. Crookes proposes (in the passage already cited) to add a *fourth,* the power of producing an electric current in a thermopile ; and a *fifth,* the power of producing mechanical motion when acting on light bodies freely suspended in a vacuum." Again, if Dr. Carpenter had consulted the *Philosophical Transactions* for 1876 (p. 361), he might have done Mr. Crookes more justice and might have given him credit for the discovery of a *sixth* attribute of radiation—(Mr. Crookes there mentions one more effect which the same ray can produce : "concentrate it on the hand by a lens, it raises a blister accompanied with pain"),—and, if he had read a few lines further, he might have spared himself the trouble of explaining to Mr. Crookes that the electric current of a thermopile is not directly excited by the incident radiation, for he would have found that this action, in common with the pain and the blister and the motion of the mercury in a thermometer, is there spoken of as being an effect of *heat.* I think it must be evident to any one who will read this passage attentively with its context (either in *Proc. Roy. Soc.* [February 10, 1876], from which apparently Dr. Carpenter quotes, or in the *Phil. Trans., loc. cit.*), that it has nothing at all to do with either one or more new forces, but that the whole gist of it is to assert that, whatever may be the mode in which radiation produces mechanical force, the result is to be attributed to it *as a whole* and not to a particular constituent assumed for the purpose.

As though with the object of covering a retreat, Dr. Carpenter says, near the end of his letter, that "Prof. G. Carey Foster will doubtless be able to pick out *points of detail* in my article, as to which faults may be found by a severe critic." I may therefore point out that I have so far carefully confined myself to what he himself singles out as the "main issues" of the question between us, and that, in my further remarks, I shall treat the matter from a still more general point of view.

In speaking (in my address at Plymouth) of the "tendency" of Dr. Carpenter's article, I meant to indicate that I referred in what I said about it to what seemed to me to be its general drift and tone, rather than to any particular passage or passages. And my judgment of the drift of the article was formed not only from what I found in it, but also from what I did not find there. For example, if Dr. Carpenter had thought as highly as I do of Mr. Crookes's work he would almost inevitably have pointed out more emphatically than he did the really astonishing number, variety, and laboriousness of his experiments ; he would also, I think, have pointed out that (with the important exception of Dr. Schuster) scarcely one of the numerous investigators, who, in consequence of his researches, have occupied themselves more or less with the radiometer, had obtained any significant experimental result which Mr. Crookes himself had not anticipated ; and he would have shown that the discovery of the radiometer, while affording a remarkable illustration of the importance of following up unexplained though apparently trivial phenomena, illustrates no less forcibly the truth that scientific discoveries are not chance revelations, coming now to one and now to another, but that they are made only by those who have eyes to see a clue when it is offered them, and patience and skill to follow where it leads.

Turning to what the article did contain, I think it is not incorrect to say that it tended to produce the impression that Mr. Crookes, more or less obstinately, and on insufficient grounds, rejected a satisfactory explanation of his results. I will therefore try to state, as shortly as I can, what seems to me to be the true state of the case in relation to this point.

Prof. Reynolds (in his paper read before the Royal Society on June 18, 1874) undoubtedly showed that a mechanical reaction, such as might account for the results obtained by Mr. Crookes, might arise when heat is communicated from a solid surface to a vapour or gas, but he did not (then at least) show that in Mr. Crookes's vacua there was enough residual gas to produce the results he ascribed to it. Mr. Crookes, without disputing the possibility of the action pointed out by Prof. Reynolds, made experiments from which he concluded that it was insufficient to explain the movements he had observed. (I must here remark that Mr. Crookes did not say, as Dr. Carpenter asserts that he did, that the explanation offered by Prof. Reynolds was one that "it is impossible to conceive." His words were : "It is impossible to conceive that in *these* experiments sufficient condensable gas or vapour was present to produce the effects Prof. Osborne Reynolds ascribes to it. After the repeated heating to redness at the highest attainable exhaustion, it is difficult to imagine that sufficient vapour or gas should condense on the movable index to be instantly driven off by a ray of light, or even the warmth of the finger, with recoil enough to drive backwards a heavy piece of metal."—*Phil. Trans.*, 1875, p. 547. But although Prof. Reynolds is unquestionably entitled to the credit of having originated the fundamental idea and worked out many of the details of the explanation that seems now to be generally adopted, his explanation not only rested on a somewhat slender experimental basis, but was theoretically incomplete, and in particular it did not show clearly why so high a degree of rarefaction should be needed for the production of the phenomena in question. An important step towards supplying this deficiency was taken by Profs. Tait and Dewar (July, 1875), who showed how the increase, resulting from rarefaction, in the mean length of the path of the gaseous molecules would favour the action, but the explanation in the form which they gave to it required that the rarefaction should be carried far enough to make the mean length of path of a molecule of gas great as compared with the dimensions of the inclosing vessel. It has, however, been pointed out by Prof. Zöllner (*Pogg. Ann.*, February, 1877), and more recently by Mr. Tolver Preston (*Phil. Mag.*, August, 1877), that, in the majority of cases, this condition is far from being fulfilled. On the other hand, the residual-gas theory of the action of the radiometer received very important experimental support from Dr. Schuster's beautiful demonstration (February, 1876) that the force exerted on the discs was correlative with an equal opposite force exerted upon the glass envelope. The complete proof that the action was due in some way to the presence of residual gas was furnished by Mr. Crookes's own discovery (June, 1876) that it rapidly diminishes when the exhaustion is carried beyond a certain point depending on the nature of the gas. The outstanding defect in the theory was removed by Mr. Johnstone Stoney, who (*Phil. Mag.*, March and April, 1876) showed that the observed phenomena might arise at a degree of rarefaction at which the mean length of path of a molecule was still much below the distance from the discs to the envelope, it being sufficient that this distance should not be too great to allow the warming of the discs to cause a sensible increase in the velocity with which the molecules struck the glass. Mr. Stoney's form of the theory answers to all the facts of the case, so far as I am acquainted with them, and it has been confirmed and illustrated by Mr. Crookes with a numerous series of remarkably beautiful and ingenious experiments.

My object in thus tracing the chief stages in the growth of the accepted theoretical explanation of the radiometer has been to point out that the quality of mind which led Mr. Crookes to reject the various suggested explanations of the phenomena he had observed, so long as they were only approximate and did not account for *all* his facts, was merely a further exemplification of the quality which led him to the original discovery. If he had been content to disregard a seemingly trivial fact he would never have made this discovery at all, and if he had disregarded slight defects in the explanations that were offered he would have missed some of its most important consequences. I think that this also might have been suitably included among the "Lessons of the Radiometer." G. CAREY FOSTER

University College, London, October 27

HAS Dr. Carpenter allowed himself to become possessed by a "dominant idea?" From his letter in NATURE (vol. xvi. p. 544), I infer that he *might* have taken the trouble to reply to my article in the July number of the *Nineteenth Century*, had he not thought that my assertions "were well known in the scientific world to be inconsistent with fact."

Some remarks, however, made by Prof. G. Carey Foster at the British Association seem to have forced upon Dr. Carpenter the conviction that he may have underrated my character for veracity, and that the "scientific world," at all events, is not unanimous in regarding my "assertions" as falsehoods. Dr. Carpenter therefore seeks in your columns to justify the statements contained in his article on "The Radiometer and its Lessons," in the *Nineteenth Century* for April last.

When Dr. Carpenter declares my "assertions (1) . . . (2) . . . (3)" to be false, I have a right to demand that Dr. Carpenter give my identical words, and not his own interpretation of my words—an interpretation which is "inconsistent with fact."

To show Dr. Carpenter's inaccuracies in small things as well as great, I may point out that he does not even quote correctly the title of my article in the *Nineteenth Century* His carelessness in more important matters is of deeper consequence. In order to enforce one of his dominant ideas "yet more fully and emphatically," he tells us that he applied himself to a "careful reperusal of" my papers "with the most earnest desire to present a true history of the whole inquiry." A most laudable determination! And where, will it be believed, did Dr. Carpenter, a Fellow of the Royal Society, go for information? To the *Philosophical Transactions*, where my papers are printed at full length? No! He only referred to the "*Proceedings* of thd Royal Society," a record, as every one knows, that contains brief, and therefore imperfect abstracts of what is published in full in the *Transactions.*

In his "justification" Dr. Carpenter quotes a passage from a lecture I delivered in 1874, on The Repulsion Accompanying Radiation, commencing, "my own impression is," &c. Had Dr. Carpenter quoted the next paragraph, which is necessary to a correct interpretation of the sentence he did quote, your readers would have been enabled to judge how far I advanced theories of my own. My words were these: "I do not wish to insist upon any theory of my own. . . . The one I advance is, to my mind, the most reasonable, and, as such, is useful as a working hypothesis, if the mind must have a theory to rest upon. *Any* theory will account for *some* facts, but only the true explanation will satisfy *all* the conditions of the problem, and this cannot be said of either of the theories I have already discussed." My next paragraph concludes with the following quotation from Sir Humphry Davy:—"When I consider the variety of theories which may be formed on the slender foundation of one or two facts, I am convinced that it is the business of the true philosopher to avoid them altogether. It is more laborious to accumulate facts than to reason concerning them; but one good experiment is of more value than the ingenuity of a brain like Newton's."

With regard to my having "theorised on the subject," I have never denied having done so, although I have on five or six occasions specially stated that "I wished to keep free from theories," and "unfettered by the hasty adoption" of theories. But I do deny that I ever stated that my results were definitely explained by the direct mechanical action of light. Your readers will understand that an experimental research is necessarily and slowly progressive, and that the early provisional hypotheses have to be modified, and perhaps altogether abandoned, in deference to later observations. Until my experiments confirmed the explanation given by Mr. Johnstone Stoney, I adopted no definite theory, and I contend that a trained physicist would fail to gather from my published papers that I desired my first impressions to be regarded as final

Dr. Carpenter again attributes to me the terms "a new force," or a "new mode of force," as applied to the repulsion accompanying radiation. Unless Dr. Carpenter can point these words out in my published papers, he has no right to place them between inverted commas.

But the chief burden of Dr. Carpenter's song is that "Mr Crookes has another side to his mind, which makes Mr. Crookes the spiritualist almost a different person from Mr. Crookes the physicist." I fail to see how the investigation of certain phenomena called spiritual can make a man a spiritualist, even if he comes to the conclusion that some of the phenomena are not due to fraud. My position in this matter was clearly stated some years ago, and I ask your permission to quote the following passages from an article I published in 1871:—"I have desired to examine the phenomena from a point of view as strictly physical as their nature will permit. . . . I wish to be considered in the position of an electrician at Valentia examining, by means of appropriate testing instruments, certain electrical currents and pulsations passing through the Atlantic cable; independently of their causation, and ignoring whether these phenomena are produced by imperfections in the testing instruments themselves, whether by earth currents or by faults in the insulation, or whether they are produced by an intelligent operator at the other end of the line."

From this stand-point I have never deviated. Can Dr. Carpenter say that his position and mine, in respect to the investigation of the phenomena ascribed to spiritualism, are so very different? He asserts that he has shown beyond doubt that it is all imposture. But I would ask if this was proved to his satisfaction twenty years ago, why does he still waste valuable time in interviews and sittings with so called mediums? If I am to be censured for having devoted time to this subject, such censure must be doubly applicable to a man who commenced the investigation when I was a child, and who cannot let the subject drop whenever a new "medium" comes in his way. Does he regard the subject as his own special preserve, and may his demonstrations against other explorers in this domain of mystery be looked upon as the conduct of a gamekeeper towards a suspected poacher?

To impress on the world that he has no "*animus*," Dr. Carpenter says he "cordially" and "personally congratulated" me. His words bring vividly to my mind the conversation, of which, by the by, he has omitted an important part. It was at the annual dinner of the Fellows of the Royal Society on November 30, 1875, when the royal medal was awarded to me. Dr. Carpenter accosted me with great apparent cordiality, and said, "Let us bury the hatchet! Why should scientific men quarrel?" I signified my full acceptance of the offered peace, and great was my surprise soon after to find that, unmindful of the understood compact, he had exhumed his hatchet and was dealing me unexpected and wanton strokes, tempered by a certain amount of half praise which reminds me of the sort of caressing remonstrance of Majendie in the pre-anæsthetic days, to the dog which he had on his operating table—"*Taisez vous, pauvre bête!*"

In all seriousness, however, I must again ask, what is the meaning of the "personal antagonism," and the persistent attacks which Dr. Carpenter, for the last six years, has directed against me? In his recently published book, in the *Nineteenth Century*, and in his last letter to you, the key-note struck in the *Quarterly Review* six years ago is sustained. We have the same personalities, the same somewhat stale remark about my double nature, and the same exuberance of that most dangerous and misleading class of averments, half truths. Dr. Carpenter, indeed, condescends to admit that I have pursued "with rare ability and acuteness a delicate physical investigation in which nothing is taken for granted without proof satisfactory to others as well as to himself," and that I have "carried out a beautiful inquiry in a manner and spirit worthy of all admiration;" but, after granting so much, he dissembles his love and proceeds to "kick me down stairs." I am damned with faint praise, and put to rights in such a school-masterly style, that I could almost fancy Dr. Carpenter carries a birch rod concealed in his coat-sleeve. He admits that in an humble and subordinate sphere I have done useful work, only I must not give myself airs on that account. Dr. Carpenter reminds me of Dr. Johnson defending Sir John Hawkins, when he was accused of meanness. "I really believe him," said Johnson, "to be an honest man at the bottom; but to be sure he is penurious, and he is mean, and it must be owned he has a degree of brutality, and a tendency to savageness, that cannot easily be defended." In the same magnanimous spirit Dr. Carpenter allows that I have contributed a trifle to science, but he does not forget to add that I am the victim of cerebral duplicity, and I am again held up to illustrate the sad result of neglecting to train and discipline "the *whole* mind during the period of its development," &c.

I have, it appears, two allotropic personalities, which I may designate, in chemical language, Ortho-Crookes and Pseudo-Crookes. The Ortho-Crookes, according to Dr. Carpenter, has acquired "deserved distinction as a chemist." He carries out a "beautiful inquiry in a manner and spirit worthy of all admiration." He has shown "ability, skill, perseverance, and freedom from prepossession." He pursues "with rare ability and astuteness a delicate physical investigation." He evinces the "spirit of the true philosopher," and he has "deservedly" received "from the Royal Society the award of one of its chief distinctions."

But Pseudo-Crookes, whose career Dr. Carpenter has evidently watched almost from his cradle—as he professes to know the details of his early education—unfortunately took a "thoroughly unscientific course," and developed into a "specialist of specialists." He had "very limited opportunities" and "never had the privilege of associating" with scientific men, although he displayed "*malus animus*" "towards those with whom he claims to be in fraternity." He is "totally destitute of any knowledge of chemical philosophy, and utterly untrustworthy as to any inquiry" not technical. His "assertions" are "well known in the scientific world to be inconsistent with fact." He enters on inquiries "with an avowed foregone conclusion of his own." He has "lent himself to the support of wicked frauds." He has "prepossessions upon which clever cheats play." His "scientific tests" are not "worthy of trust." He is a believer in "day dreams," and the supporter of a "seething mass of folly and imposture;" whilst, to crown all, he actually thinks that the radiometer is driven "by the direct impetus of light." In short, this Pseudo-Crookes is a compound of folly and knavery such as has rarely, if ever, previously been encountered.

WILLIAM CROOKES (The Ortho-Crookes?)

London, October 29

Mr. Wallace and Reichenbach's Odyle

I AM amazed that Dr. Carpenter should think it necessary to make public, with such haste, Prof. Hoffmann's statement that Baron Reichenbach's facts and theories are not accepted by the body of scientific men in Germany. Of course they are not. But how this affects their intrinsic accuracy I fail to see. Less than twenty years ago the scientific men of all Europe utterly disbelieved in the co-existence of man with extinct animals; yet the facts adduced by Freere, Boué, McEnery, Godwin Austen, Vivian, and Boucher de Perthes, are now admitted to have been trustworthy and deserving of the most careful examination. The whole history of scientific discovery from Galvani and Harvey to Jenner and Franklin, teaches us, that every great advance in science has been rejected by the scientific men of the period, with an amount of scepticism and bitterness directly proportioned to the novelty and importance of the new ideas suggested and the extent to which they run counter to received and cherished theories. Rejection is one thing, disproof is another; and I have in vain searched for anything like disproof, or even rational explanation, of Reichenbach's facts: his theory, or "Odyle-doctrine," I have never "attempted to rehabilitate," as Dr. Carpenter, with his usual misconception, says I have done. In my review of Dr. Carpenter's lectures (*Quarterly Journal of Science*, July, 1877, p. 396), I adduce five tests employed by Reichenbach, and also the independent and simultaneous confirmation of Dr. Charpignon in France; and the only reply I get is: "All men of science disbelieve them." With the facts of history above alluded to in my mind, and believing that human nature is very much the same in the nineteenth century as it was in the eighteenth, I can only say, "so much the worse for the men of science."

Dr. Carpenter's reference to the believers in a flat earth, as a parallel case, is unfortunate, because the two cases are really of a totally different nature. Those who maintain the earth to be flat do not deny the main facts which we rely on as proving it to be round, but they attempt to give other explanations of them. The dispute is on a question of reason and inference; and every intelligent and fairly educated man is able to decide it for himself. But in Reichenbach's case it is the *facts* that are rejected without disproof or adequate explanation. The two cases are therefore quite distinct, and Dr. Carpenter's attempted parallel, as well as his setting up of scientific disbelief as a conclusive reply to evidence, is in conformity with his whole treatment of this subject.

I trust that such of the readers of NATURE as may feel any interest in the questions at issue between Dr. Carpenter and myself will read my article above referred to, and not allow themselves to be influenced by Dr. C.'s repeated appeals to authority and to prejudice. ALFRED R. WALLACE

I HAVE to request your insertion of a post-card I have this morning received, for two reasons; *first*, because, as it is anonymous, and as the writer of it is obviously a reader of NATURE, no other way is open to me for replying to it except that which your columns may afford; and *secondly*, because it is a very curious example of the misconceptions into which men are apt to fall who allow themselves to become "possessed" by "dominant ideas."

"If Mr. A. R. Wallace has to choose between being either 'a fool or a knave,' there is *at all* events *no choice* left for *the man* who deliberately and maliciously makes incorrect assertions and suppresses the truth to further his own views. I dare say you know what most people would call such a man. Yours,

"ONE WHO WAS AT PLYMOUTH"

Now, in the first case, it must be perfectly obvious to any one who is capable of reasoning logically, that nothing which I said of Mr. Wallace in your last number can be twisted into the implication that he is either "a fool or a knave." John Hampden is continually saying this of Mr. Wallace and of everybody who upholds the rotundity of the earth. And I mildly suggested whether, in putting himself in opposition to the whole aggregate of scientific opinion on the value of Reichenbach's Odylism—not because he had himself repeated them, but because he believes in Reichenbach—Mr. Wallace is not assuming an attitude in some degree similar, that is, setting himself up as the one wise and honest man who duly appreciates Reichenbach, and therefore implying that everybody else is either stupidly or wilfully blind to the evidence he presented. If anyone thinks it worth while to read Mr. Wallace's review of my lectures on "Mesmerism, Spiritualism," &c., in the last number of the *Quarterly Journal of Science*, he will be able to judge whether I have or have not wronged Mr. Wallace in this matter.

The writer's appreciation of my own character, which has frequently been expressed to me before in the same manner and in the like terse and elegant language, is now enforced by what he deems to be Prof. Carey Foster's judicial opinion, delivered at the Plymouth meeting; and I find myself, therefore, fully justified in my opinion that by his introduction of the word "intentionally" Prof. Carey Foster made his judgment legitimately bear a meaning, which, as he has stated, he would consider insulting to my character. And I cannot but believe that Prof. G. Carey Foster will regret having thus given a new handle to a man who obviously *wishes* to insult me on account of my antagonism to spiritualism. As the writer of the post-card continues to use Prof. G. C. Foster's authority, *after* that gentleman's explicit disavowal of the offensive meaning here attached to it, and as I may, of course, expect that he will continue to avail himself of that authority, I should like him to kn through your columns that it is scarcely worth while for him to trouble himself to repeat these attacks, since they have long since ceased to do anything else than amuse me, and will only furnish me with materials for amusing other people.

It seems much to be regretted that neither spiritualism nor attendance at the meetings of the British Association, nor even the reading of NATURE seems able to teach this person to behave like a gentleman.
WILLIAM B. CARPENTER

October 29

Potential Energy

YOUR correspondent "X." has described some of his troubles respecting potential energy. Many a learner could describe similar troubles respecting force and energy in general. They who earnestly contend for definiteness and accuracy do not always teach with definiteness and accuracy. For example: in his "Treatise on Heat," p. 137, Dr. Tyndall tells me that by raising a weight from the floor I have conferred upon the weight potential energy. Presently he tells me that this energy is derived (not from me, but) from the pull of gravity. He next tells me that we might call the energy with which the weight descends, moving force, *i.e.* he teaches me to confuse force and energy; and after all this he bids me remember that "exactness is here essential. We must not now tolerate vagueness in our conceptions."

Take another example. In his lecture on "Force" (NATURE, vol. xiv. p. 462), Prof. Tait teaches that force is a mere name, and that it has no objective existence; he also teaches that the product of this non-existence by its displacement has an objective existence. Few learners would say that is a very lucid statement. Again, in the same lecture he says "there is no such thing as centrifugal force, and accelerating force is not a physical idea at all;" but in his "Nat. Phil." he speaks of both these forces, and describes their effects (Nos. 185, 187, 598, 248).

When teachers deservedly eminent make statements like the foregoing, so likely to mystify and confuse a novice, it is no wonder that there is a good deal of smattering in popular science.

Prof. Tait says "the so-called accelerating force is really no force at all, but another name for the kinematical quantity acceleration." I venture to entirely disagree with this statement, and for the following reason:—$\frac{dv}{dt}$ is a *number*, and may be that number of units of *force*, or that number of units of *acceleration*. When it is called accelerating force it is the representative of $m\frac{dv}{dt}$, when $m = 1$, and m does not appear in the expression and it means $\frac{dv}{dt}$ units of *force*. When it is called acceleration it means $\frac{dv}{dt}$ units of *acceleration*. Accelerating force is just a real as moving force, for it is, in fact, the mth part of the moving force. In like manner v may mean either v units o velocity, or v units of momentum; in the latter case it is the representative of mv, when $m = 1$, and means the momentum of a unit of mass which has v units of velocity. In like manner m may mean either m units of mass, or m units of momentum, or m units of kinetic energy; in the two latter cases it is the representative of mv or of mv^2 when $v = 1$, and means the momentum, or the *vis viva* of m units of mass moving with un of velocity.

A few simple definitions would remove the difficulties respecting force. Thus: If a mass of m units of mass is at any instant receiving an acceleration of a units of acceleration in any given direction, the force which is acting on it at the given instant in the given direction is ma units of force. The force acting on the mass in the *direction of its motion* is called the moving force. The force in the normal to the direction of its motion and towards the centre of curvature is called the centripetal force. An equal and opposite force is called the centrifugal force. The mth part of the moving force is called the accelerating force, which is the moving force acting on a unit of mass.

In the case of a planet's orbit it is too common to give the name centrifugal force to two forces which generally differ both in magnitude and in direction, one of them being in the direction of the normal, the other in the direction of the radius-vector. This is the last instance which I shall give of sins against definiteness and accuracy.
E. G.

Bardsea

Hartlaub's "Birds of Madagascar"

THE excellent review, exhibiting traces of a master's hand, of the above-named useful work, which appeared in NATURE (vol. xvi. p. 498) prompts me to offer some remarks on the ornithology of Madagascar and its neighbouring islands, and to take exception on two points therein laid down.

The first of these is propounded by your reviewer and seems to me absolutely contrary to fact. He says:—"Compared with Madagascar itself the appendent island groups are poor in species, although in every case there are many interesting forms among their winged inhabitants. The Comoro Islands muster only some forty-four species of birds, Mauritius about sixty, of which fifteen or sixteen have been introduced by man's agency, and Bourbon about the same number, while Rodriguez appears to have only about twenty-five species now existing in it, of which four or five are certainly recent introductions."

Now twenty years ago my friend, Mr. Sclater, in that remarkable paper of his on the geographical distribution of birds (*Journ. Linn. Soc.* Zoology, ii. p. 130), which so happily laid the true foundation for our present researches into the subject, showed that the proper mode of comparing the wealth or poverty of one fauna with another was to state the proportion which the number of species composing it bears to the area over which they range. The same view was adopted very shortly after by Mr. Wallace, who took occasion (*Ibis*, 1859, p 449) to question certain of Mr. Sclater's results, and its correctness seems to have been since generally admitted. Yet, applying this test to Madagascar and its neighbouring islands, we find a state of things to exist very different from that which your reviewer has alleged. The area of Madagascar is said[1] to be 10,751 German square miles, that of the Comoros collectively 38·57, of Mauritius 34·76, of Bourbon 42·05, and of Rodriguez 5. It will be sufficient for my purpose to compare the first and last of these. Your reviewer is willing to allow twenty indigenous species to Rodriguez; then—

Area of Rodriguez.		Area of Madagascar.		Species in Rodriguez.		Species in Madagascar.
5	:	10,751	::	20	:	x

$$= \frac{10{,}751 \times 20}{} = 43{,}004.$$

But instead of an avifauna of 43,004 species, or about four times the number known to exist throughout the whole world, Dr. Hartlaub gives it 218, and your reviewer generously adds two more, making 220! Suppose (an extravagant supposition) that future explorations enable us to double the last number, it is Madagascar that will still be out of all proportion "poor in species" compared with "the appendent island groups," and not these with Madagascar.

The next point to which I must demur is that "the individuality of the fauna of Madagascar is so unique that even that of New Zealand can hardly be compared with it." I will leave to fitter hands than mine to show that this is not the case generally, and shall only remark here that it is not so with birds. Of the sub-class *Ratitæ* there have been until lately *five* strongly-marked groups, each of which is equivalent to an "order" among the *Carinatæ*. Now *two* of these groups were peculiar to New Zealand, and one (*Apterygidæ*) is so now, while the other (containing the families *Dinornithidæ* and *Palapterygidæ*) is but recently extinct. Willingly granting that *Æpyornis*, when we know more about it, may prove to form a sixth group, the balance of "individuality," if I understand the meaning of the word, will still be on the side of New Zealand. Turning to the Carinate birds, *Harpagornis* stands alone, while *Cnemiornis* will certainly count for as much as the *Dididæ*. The extraordinary Mascarene Rails (*Miserythrus* and *Aphanapteryx*) are well represented by *Ocydromus*, which so much resembles them, and *Strigops* is undoubtedly a more abnormal form than, so far as we can judge, either *Lophopsittacus* or *Necropsittacus*; just as *Nestor* is more aberrant than *Coracopsis*, and *Heterolocha* than either *Fregilupus* or *Necropsar*. But there is no need to continue the list, and in conclusion I will only declare that I think far too highly of the fauna of Madagascar and of the Mascarene Islands to wish that its extraordinary peculiarities should be undervalued, though I do not want them to be unduly magnified at the expense of those of the fauna of New Zealand.

ALFRED NEWTON

Magdalene College, Cambridge, October 27

Eucalyptus

HAVING read with great interest the article in your journal (vol. xvi. p. 443) on the *Eucalyptus* I take the liberty of sending you a pamphlet on the same subject, in which I have endeavoured to unite all the arguments likely to persuade and convince the Italians of the immense utility of the above-named tree, the cultivation of which would be of the greatest importance for the *Agro Romano*.

As is well remarked in the article in NATURE, the *Eucalyptus* is extensively cultivated in France, Spain, and Portugal. But in Italy, where it prospers almost all over the country and might be cultivated with facility, in spite of the most earnest efforts on my part during my residence here for the last ten years, in spite of its being recommended in Parliament by one of the most influential members, it has not been adopted.

In my gardens on the Lake Maggiore, I cultivate forty different varieties of the *Eucalyptus*. Of these the *amygdalina* and the *globulus* have attained, in eight years, the height of 17 metres. It is to be remembered that the temperature has sometimes been as low as 7° C. below zero without injury to these plants.

If you consider it probable that these few words could be of interest to your readers I willing authorise you to publish them in your estimable journal. PRINCE PIERRE TROUBITZKOY

Villa Troubitzkoy, near Intra, Lago Maggiore, October 15

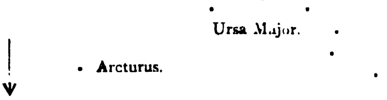
THESE trees are now attracting so much attention that even the small amount of experience I may be able to offer may not be unacceptable to your readers. Considerable stress is laid upon their influence in dissipating malaria; but I have not found this to be the case in Queensland, one of the head-quarters of the tree. I have personally suffered from malaria in the very heart of a forest extending for many miles in every direction, and composed mainly of all the varieties of *Eucalyptus*, and not by any means remarkable for the extent of swampy ground, and have known many instances of febrile attacks among shepherds and stockmen in the locality. Moreover I was told on inquiry that these attacks were not confined to any particular year, but that every year some cases might be expected. I was greatly surprised at reading in your "Notes" (NATURE, vol. xvi. p. 557) that the mosquitoes had disappeared with the introduction of the "gum" trees into Algeria. This would not be the experience of any one who has lived in Australia, I believe. I have found these pests so intolerable on high land, where almost the only tree to be found was one variety or other of *Eucalyptus*, and sometimes all, that sleep was impossible while camping out at night, and life a burden in the day by reason of these pests. The gums emit a most decided odour, especially in strong sunlight. When riding across the great Queensland plains and approaching wooded spurs I have (*Scotticè*) "felt" the characteristic smell of the gums at a considerable distance. These plains—ten miles in breadth—are not crossed in a short time, and the resinous odour of the gums, omnipresent in the forest and scarcely noticed there, strikes one forcibly when approaching the trees after the olfactory organs have been for some time deprived of it. Whether this odour has any effect or whether it is *the* preservative against malaria, I do not know. The growth of these trees in South America is very rapid. When in the Banda Oriental some years ago I examined a plantation of red and blue gums, then eight years old. The trees were at least forty feet high, and many of them measured thirty-six inches in circumference at three feet from the ground. They had a profusion of foliage such as I have never seen on the same trees in Australia. This was right out on "pampa" land, in deep alluvial soil. These trees had fought their way up, in spite of the black ants so destructive to foliage—the owner told me that they had at first stripped the young trees—and the tremendous gales which sweep over this open country. Those to the westward and south-westward of the plantation were far inferior in size to those on the east and north. This was the only grove of *Eucalypti* in the Banda, and it demonstrates the possibility of covering the naked pampas to any extent with forest. English settlers in the River Plate countries should note this fact, and I am sure the enlightened owner of the Estancia "Sherenden" would supply any of his countrymen with seed.

ARTHUR NICOLS

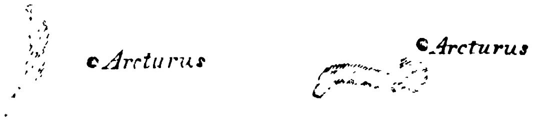
Meteor of October 19, 6.15 P.M.

THE large meteor described by two correspondents (NATURE, vol. xvi. p. 551) was observed also by several persons in this district, but most of the accounts are so meagre and doubtful as to possess little scientific value. The meteor appears, however, to have been well seen by Mr. W. Watkins Old, of The Parade, Monmouth, and his notes are so interesting that I beg to transcribe them. He says:—

"The meteor fell at 6.15 exactly. It appeared to me to descend perpendicularly some degrees from and to the west of Arcturus (which was shining brightly), and it disappeared behind a bank of dark cloud above the horizon at a point in a line projected beyond Arcturus, half the distance between that star and the last of those in the tail of Ursa Major, as roughly shown in the diagram below:—



Thus it remained stationary, like a dazzling white wand, while I counted twenty, during which time I could perceive the vapour, of which the trail was composed, as it were in ebullition. It then gradually curved towards the north as depicted in the following sketch; and drifted slowly away during *eight* minutes,



until it lay almost horizontal though still brightly illuminated, while the clouds gradually rose and covered it from my view. Altogether I observed it over eight minutes by my watch. There was much twilight in the west and the moon was shining brightly from which one may judge the extreme brilliancy of the meteor. I should add that when it appeared there was simultaneously a sensible rent or flip, like one sometimes hears with a sharp flash of lightning, and which may possibly be due to the appulse of light, as it could scarcely be the sound of explosion if there was any. It was too simultaneous to be the report of the descent of the meteor through the air, but it was sufficiently loud to be pronounced and caused some people standing near me, with their backs to the west, to inquire what it was, though they evidently saw nothing of the meteor nor even turned towards its direction. I listened but heard no further sound."

Ashleydown, Bristol, October 26 W. F. DENNING

Curious Phenomenon during the Late Gale

YOUR correspondent, "G. A. M." (vol. xvi. p. 551), may be interested to know that the "ball of fire" he saw descend on the evening of the 14th inst. was seen here by me, and by those who accompanied me, at precisely the same time (6.50 P.M.) that he mentions. We were walking in a south-easterly direction, and it seemed to fall from about half-way between that point of the compass and the moon, which was due south of us, and shining brightly. The ball itself appeared to us luminous white, while the "wake" left in its passage through the air, was bluish green. It was visible, I should say, for twenty seconds.

Occurring, as it did, at a time when thousands were wending their way to church, it must have been very generally observed.

Harrow, October 26 A. W. B. J.

Singing Mice

WHEN at school a friend and I used to keep tame mice, and amongst our large stock was one of the so-called singing mice. The mouse in question was not one we bred ourselves, but was bought from a London dealer, so we had no opportunities of knowing whether it had ever been kept near a singing bird or not; but it was not at all averse to performing in broad daylight, and would chirp whilst a knot of boys were standing round it as freely as when the cupboard was closed.

As M. Brierre describes it (vol. xvi. p. 558), the mouse used to sit with its snout more or less elevated, but not at all to an uncomfortable height, and its throat used to throb like that of a bird whilst singing, the fur of the one being ruffled like the feathers of the other; and the song was something between that of a wren and that of a shrew mouse, and rather pleasing than otherwise.

At first we were inclined to attribute the noise to disease of the lungs or throat, but were unable to hold that opinion long, as there never seemed to be any pain or gasping connected with it, but the noise was always produced at periods of greatest rest, and chiefly when the mouse came out of its sleeping place to wash its face and paws, at which times it generally chirped at intervals. It never had the power of imparting the art to others, nor did any of its numerous progeny inherit its powers. Neither was it all short lived, but rather the contrary, and its death was caused by an accident. We were unable to consider the power of emitting the sounds at all the result of weakness or disease.

HENRY H. SLATER

Sound-Producing Arthropods

I HAVE read with much interest the brief abstract given in NATURE (vol. xvi. p. 567) of Mr. Wood Mason's announcement to the Entomological Society of the discovery of stridulating organs in association with scorpions; reference being made at the same time to his recognition of similar sound-producing structures among other Arthropoda, including certain Crustacea. In this latter case no mention is made of the particular types with which these sound-organs have been observed, and I therefore hazard the relation of an instance that has recently fallen under my own observation with the chance of its proving a newly-recorded example.

The crustacean in question, which I have ascertained to possess sound-producing properties to an eminent degree, is a species of *Sphcroma*, belonging to the Isopodous order of the class. I have not as yet ascertained the exact method in which sound is produced nor whether the animal has organs specially adapted for the purpose; on numerous occasions, however, my attention has been attracted to the glass jar of which, with the exception of microscopic Copepods and Protozoa, a single specimen of the species is the sole animal occupant, by a little sharp tapping sound produced three or four times consecutively with intervals of about one second's duration, and which I can almost exactly imitate by gently striking the side of the jar with the pointed end of a pipette. On being approached the little creature always endeavours to elude notice by passing to the opposite side of the stalk of seaweed, upon which it usually reposes in the same way that a squirrel dodges round the branch of a tree, and on no occasion so far have I been able to catch the little fellow *flagrante delicto*, or in the act of producing the sound which it most undoubtedly emits. The character and intensity of the sound produced associated with the small size of the animal, scarcely one quarter of an inch in length, induces me to believe that it is caused by the sudden flexion and extension of the creature's body. A more prolonged observation will no doubt clear up this point, but Mr. Wood Mason may possibly be in a position to throw further light upon the subject by means of the evidence he has collected in reference to other crustacean types.

Among the higher Decapodous crustacean order one species, *Alpheus ruber*, frequently collected by me in Guernsey, produces a snapping noise beneath the water by the sudden extension of the terminal joint of its larger claw that can be heard at a considerable distance, and that at once betrays its lurking place to a practised ear. The large sea crayfish (*Palinurus quadricornis*) again, often emits when handled what may be fitly described as a shrill squeaking sound by the rubbing together of the spinous abdominal segments. It would seem indeed that a closer study of the life habits of the aquatic Arthropoda is likely to reveal among its members as infinite a variety of sound-producers as has hitherto been determined to exist among their more familiar terrestrial congeners.

Insects and Flowers

IN reference to the question whether insects are most attracted to flowers by scent or colour, may I mention that while staying at the hotel at Cettinge lately I was amused by the behaviour of some humming-bird sphinx moths. My room was roughly stencilled with a "spotty" pattern of purplish brown on the dull white plaster. Every morning these moths, with their probosces extended, used to attack the dabs of colour, hovering before them, just as though they were real flowers, but starting back with apparent amazement on finding that they were not. This seems the more remarkable because the wonderfully abundant aromatic herbs of that region, which must have supplied their usual food, have all, so far as I know, very inconspicuous flowers

Notting Hill, October 27 A. J. H.

FRANCIS VON ROSTHORN

FRANCIS VON ROSTHORN, who died June 17, 1877, was the son of Matthew Rosthorn, of Lancashire, who went to Vienna in 1765, at the invitation of the Empress Maria Theresa, to establish the manufacture of metal buttons. He constructed the first rolling-mills in Austria; one at Vienna, another (in 1792) at Fahrafeld, in Lower Austria. Matthew von Rosthorn was ennobled by the Emperor Joseph II. in 1790, and died at Vienna January 3, 1805, leaving five sons. The youngest of these, born April 18, 1796, at Vienna, is the subject of this notice. These five brothers joined in creating extensive metallurgic establishments; the first (1817) at Oed; and another (1823) in Carinthia, for smelting zinc (then high in price) out of the Raibl and Bleyberg ores, by means of brown coal. Having purchased (1826) the state demesne of Wolfsberg, in Carinthia, with extensive metallurgical works, they constructed there a large rolling-mill, together with a puddling furnace. Francis von Rosthorn, having prepared himself for his practical career by attending the Mining Academy of Schemnitz, in Hungary (1814 to 1818), soon became acquainted with several eminent geologists, and obtained the patronage of the late Archduke John. He made several scientific tours in Carinthia, Carniola, Styria, Salzburg, and the Hungarian border; in 1827 with Prof. Keferstein, in 1828 with Archduke John, in 1829 with Escher and Schrötter, and in 1832 with Dr. Boué. His annual visits to Archduke John at Gastein (1829 to 1836) were always connected with Alpine exploration. His later travels (1842 to 1847) were chiefly southward. In 1832 he communicated the results thus obtained to the Meeting of German Naturalists at Vienna; and in 1836 to the meeting at Freiburg. In 1848 he was elected into the Legislative Assembly ("Landtag") of Carinthia; and from 1852 to 1870 held the office of President of the Commercial and Industrial Board of that province. Francis von Rosthorn's constitution was exceptionally robust, so that up to his seventy-sixth year he was able to undertake arduous Alpine ascents. His conversation with persons of any social station was unaffectedly amiable; but he could be sarcastic when he met with affectation or baseless pretensions.

SPECTRUM OF AURORA AUSTRALIS

AS I believe no account of spectroscopic observations of the Aurora Australis have as yet been published, I venture to send this description of two auroræ observed during the stay of H.M.S. *Challenger* in high southern

---

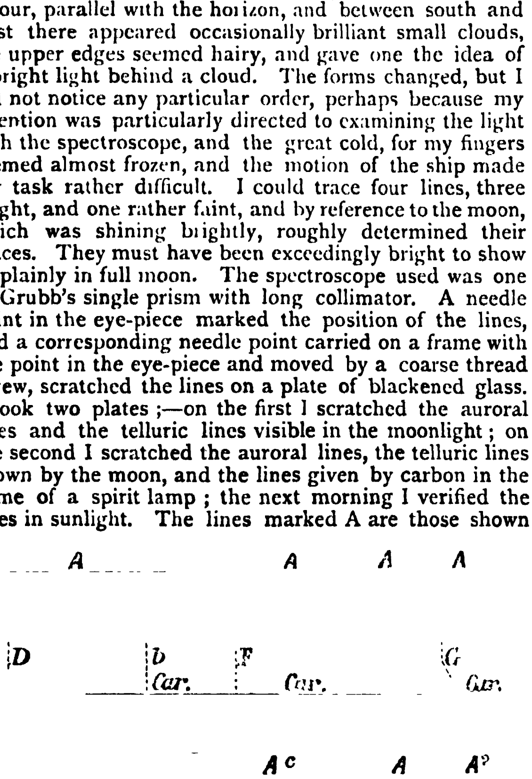
[1] Obituary Notice by Prof. E. Suess ("Report of the Imperial Geological Institute, Vienna," August 31, 1877).

latitudes. The opportunities of observing were not frequent, either from the rarity of the phenomena (which is very possible) or because the dense mass of cloud which is the prevailing feature of those regions prevented their being seen except when exceptionally bright.

Altogether four appearances were noted. The first was 1.30 on the morning of February 9, 1874, in lat. 57° S. and long. 75° E., bar. 29·0 in., ther. 35°. There were brilliant streaks to the westward; no spectroscopic observations were taken. The second was on February 21 at 9.30 P.M., lat. 64° S., long. 89° E., bar. 28·8, ther. 31°; one bright white curved streamer extended from Jupiter, which appeared to be near the focus, through Orion and about as far beyond. Under this was what appeared to be a black cloud, but the stars were visible through it. Real cumulus clouds hid great part of the remainder, but there were two vertical flashing rays that moved slowly to the right (west), generally the aurora was still and bright.

On examining the streamer with the spectroscope I found the usual three prominent lines, namely, one yellow-green, one green, the third blue or purple. I looked for the red line but could not find it.

The third aurora was seen on March 3, lat. 53° 30′ S., long. 109° E., bar. 29·1, ther. 36°, after some days wet and stormy weather. Soon after 8 P.M. the sky began to clear and the moon shone out. Noticing the light to the southward to be particularly bright I applied the spectroscope and found the distinguishing auroral line. About midnight I was called as there were very brilliant auroral clouds. The sky was almost clear, but south were two or three brilliant light clouds, colour very white yellow, shape cumulus stratus; from about west to near south extended a long feathery light of the same colour, parallel with the horizon, and between south and west there appeared occasionally brilliant small clouds, the upper edges seemed hairy, and gave one the idea of a bright light behind a cloud. The forms changed, but I did not notice any particular order, perhaps because my attention was particularly directed to examining the light with the spectroscope, and the great cold, for my fingers seemed almost frozen, and the motion of the ship made my task rather difficult. I could trace four lines, three bright, and one rather faint, and by reference to the moon, which was shining brightly, roughly determined their places. They must have been exceedingly bright to show so plainly in full moon. The spectroscope used was one of Grubb's single prism with long collimator. A needle point in the eye-piece marked the position of the lines, and a corresponding needle point carried on a frame with the point in the eye-piece and moved by a coarse thread screw, scratched the lines on a plate of blackened glass. I took two plates;—on the first I scratched the auroral lines and the telluric lines visible in the moonlight; on the second I scratched the auroral lines, the telluric lines shown by the moon, and the lines given by carbon in the flame of a spirit lamp; the next morning I verified the lines in sunlight. The lines marked A are those shown by the aurora, those marked D, *b*, F, and G are the telluric lines, and those marked *car.* were given by the carbon in the spirit lamp.



The spectrum has been magnified five times from the plates. I cannot account for the different position of the auroral lines in the two plates, as the prism was not moved during the observations that I am aware of.

The fourth aurora was a slight one seen to the southward on March 6 at 8 P.M. It would be worth investigating whether the low barometer has anything to do with the absence of red in the spectrum, the normal state of the barometer is an inch lower in those regions than in more temperate latitudes.

I may as well add that on February 9 the aurora was preceded by a watery sunset, and the day broke afterwards with high cirrus clouds and clear horizon. On February 21 the aurora preceded a fine morning, cumulus stratus clouds. On March 3 there was a brilliant sunset followed by a fine morning; and on March 6, after the slight appearance of aurora, the clouds changed to high cirrus.

J. P. MACLEAR

ABSOLUTE PITCH

AT the present time the question of absolute pitch is attracting attention in consequence of the discrepancy between König's scale and the numbers determined by Appunn's tonometer. This instrument is founded upon the same idea as Scheibler's fork tonometer, and consists of a series of sixty-five harmonium reeds, bridging over an entire octave, and so tuned that each reed gives with its immediate neighbours four beats per second. The application to determine absolute pitch, however, does not require precision of tuning, all that is necessary being to count with sufficient accuracy the number of beats per second between each pair of consecutive reeds. The sum of all these numbers gives the difference of frequencies of vibration between the first reed and its octave, which is, of course, the same as the frequency of the first reed itself.

The whole question of musical pitch has recently been discussed with great care by Mr. Ellis, in a paper read before the Society of Arts (May 23, 1877). He finds by original observation with Appunn's instrument 258·4 as the actual frequency of a König's 256 fork, and Prof. Preyer, of Jena, has arrived at a similar result (258·2). On the other hand, Prof. Mayer in America, and Prof. Macleod in this country, using other methods, have obtained numbers not differing materially from König's. The discrepancy is so considerable that it cannot well be attributed to casual errors of experiment; it seems rather to point to some defect in principle in the method employed. Now it appears to me that there is such a theoretical defect in the reed tonometer, arising from a sensible mutual action of the reeds. The use of the instrument to determine absolute frequencies assumes that the pitch of each reed is the same, whether it be sounding with the reed above, or with the reed below; and the results arrived at would be vitiated by any mutual influence. In consequence of the ill-understood operation of the wind, it is difficult to predict the character of the mutual influence with certainty; but ("Theory of Sound," §§ 112-115) there is reason to think that the sounds would repel one another, so that the frequency of the beats heard when both reeds are sounding, *exceeds* the difference of the frequencies of the reeds when sounding singly. However this may be, in view of the proximity of consecutive reeds and of the near approach to unison,[1] the assumption of complete independence could only be justified by actual observation, and this would be a matter of some delicacy. If the mutual influence be uniform over the octave it would require a difference of one beat per minute only to reconcile König's and Appunn's numbers.

As to the amount of the influence I am not in a position to speak with confidence, but I may mention an observation which seems to prove that it cannot be left out of account. If two sounds of nearly the same pitch are going on together, slow beats are heard as the result of the superposition of vibrations. Suppose now that a third sound supervenes whose pitch is such that it gives rapid beats with the other two. It is evident that these rapid beats will be subject to a cycle of changes whose frequency is the same as that of the slow beat of the first two sounds. For example, in the case of equal intensities of two sounds there is a moment of silence due to the superposition, of equal and opposite vibrations, and at this moment a third sound would be heard alone and could not give rise to beats. The experiment may be made with tuning-forks, and the period of the cycle will be found to be sensibly the same whether it be determined from the slow beat of the two forks nearly in unison or from the rattle caused by the simultaneous sounding of a third fork giving from four to ten beats per second with the other two. In the case of forks there is no fear of sensible mutual action, but if it were possible for the third sound to affect the pitch of one of the others the equality of the periods would be disturbed. The observation on Appunn's instrument was as follows:—The reeds numbered 0 and 64 being adjusted to an exact octave, it was found that the beats arising from the simultaneous sounding of reeds 0, 63, and 64 were by no means steady, but passed through a cycle of changes in a period no greater than about five seconds. In order to work with greater certainty a resonator of pitch corresponding to reed 64 was connected with the ear by a flexible tube and adjusted to such a position that the beats between reeds 0 and 64 (when put slightly out of tune) were as distinct as possible, indicating that the gravest tone of reed 64 and the octave over-tone of reed 0 were of equal intensity. By *flattening* reed 64 (which can be done very readily by partially cutting off the wind) the beats of the three sounds could be made nearly steady, and then when reed 63 was put out of operation, beats having a 5 seconds' period were heard, indicating that reeds 0 and 64 were in tune no longer. It would appear, therefore, that when reed 63 sounds the pitch of reed 64 is raised, but in interpreting the experiment a difficulty arises from the amount of the disturbance being much in excess of what would be expected from the performance of the instrument when tested in other ways.[1]

---

[1] It must not be forgotten that the vibration of the tongue involves a transference of the centre of inertia, so that there is a direct tendency to set the sounding-board into motion.

I come now to an independent determination of absolute pitch, which it is the principal object of the present communication to describe. The method employed may be regarded as new, and it appears to be capable of giving excellent results.

The standard fork, whose frequency was to be measured, is one of König's, and is supposed to execute 128 complete vibrations in a second. When placed on its stand (which does not include a resonance box) and excited by a violin bow, it vibrates for a minute with intensity sufficient for the counting of beats. The problem is to compare the frequency of this fork with that of the pendulum of a clock keeping good time. In my experiments two clocks were employed, of which one had a pendulum making about 1½ complete vibrations per second, and the other a so-called seconds' pendulum, making half a vibration per second. Contrary to expectation, the slower pendulum was found the more convenient in use, and the numerical results about to be given refer to it alone. The rate of the clock at the time of the experiments was determined by comparison with a watch that was keeping good time, but the difference was found to be too small to be worth considering. In what follows it will be supposed for the sake of simplicity of explanation that the vibrations of the pendulum really occupied two seconds of time exactly.

The remainder of the apparatus consists of an electrically maintained fork interrupter, with adjustable weights, making about 12½ vibrations per second, and a dependent fork, whose frequency is about 125. The current from a Grove cell is rendered intermittent by the interrupter, and, as in Helmholtz's vowel experiments, excites the vibrations of the second fork, whose period is as nearly as possible an exact submultiple of its own. When the apparatus is in steady operation, the sound emitted from a resonator associated with the higher fork has a frequency which is determined by that of the interrupter, and not by that of the higher fork itself; nevertheless, an accurate tuning is necessary in order to obtain vibrations of sufficient *intensity*.[1] By counting the beats during a minute of time it is easy to compare the higher fork and the standard with the necessary accuracy, and all that remains is to compare the frequencies of the interrupter and of the pendulum. For this purpose the prongs of the interrupter are provided with small plates of tin so arranged as to afford an intermittent view of a small silvered bead carried by the pendulum and suitably illuminated. Under the actual circumstances of the experiment the bright point of light is visible in general in twenty-five positions, which would remain fixed, if the frequency of the interrupter were exactly twenty-five times that of the pendulum. In accordance, however, with a well-known principle, these twenty-five positions are not easily observed when the pendulum is simply looked at; for the motion then appears to be continuous. The difficulty thence arising is readily evaded by the interposition of a somewhat narrow vertical slit, through which only one of the twenty-five positions is visible. In practice it is not necessary to adjust the slit to any particular position, since a slight departure from exactness in the ratio of frequencies brings all the visible positions into the field of view in turn.

In making an experiment the interrupter is tuned, at first by sliding the weights and afterwards by soft wax, until the interval between successive appearances of the bright spot is sufficiently long to be conveniently observed. With a slow pendulum there is no difficulty in distinguishing in which direction the pendulum is vibrating at the moment when the spot appears on the slit, and it is best to attend only to those appearances which correspond to one direction of the pendulum's motion. This will be best understood by considering the case of a conical pendulum whose motion, really circular, appears to be rectilinear to an eye situated in the plane of motion. The restriction just spoken of then amounts to supposing the hinder half of the circular path to be invisible. On this understanding the interval between successive appearances is the time required by the fork to gain or lose one complete vibration as compared with the pendulum. Whether the difference is a loss or a gain is easily determined in any particular case by observing whether the apparent motion of the spot across the slit (which should have a visible breadth) is in the same or in the opposite direction to that of the pendulum's motion.

In my experiment the interrupter *gained* one vibration on the clock in about eighty seconds, so that the frequency of the fork was a thousandth part greater than 12·5 or 12·51. The dependent fork gave the ninth harmonic, with a frequency of 125·1. The beats between this fork and the standard (whose pitch was the higher) were 180 in sixty seconds, so that the frequency of the standard was as nearly as possible 128·1, agreeing very closely with König's scale. The error of the determination may amount to ·1, but could not, I think, exceed ·2.

---

[1] The value of my instrument has been greatly enhanced by the valuable assistance of Mr Ellis, who was good enough to count the entire series of beats, and to compare the pitch with that of the tuning-forks employed by him in previous investigations. Mr. Ellis, however, is not responsible for the facts and opinions here expressed. It may be worth mentioning that the steadiness or unsteadiness of the beats heard when three consecutive reeds are sounding simultaneously is a convenient test of the equality of the consecutive intervals. The frequency of the cycle of the four a second beats is equal to the difference of the frequencies of either of the actual extreme notes and that which, in conjunction with the other two, would make the intervals exactly equal.

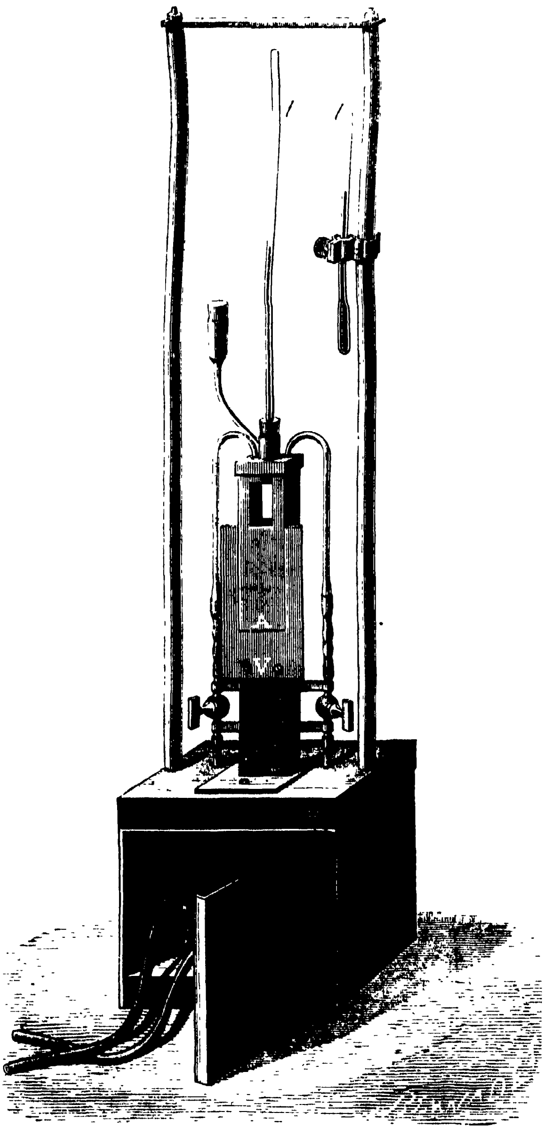
[1] This tuning is effected by prolonging as much as possible the period of the beat heard when the dependent fork starts from rest. This beat may be regarded as due to an interference of the forced and natural notes.

I ought to add that the *approximate* determination of the frequency of the interrupter must be made independently, as the observation on the pendulum does not decide *which* multiple of ½ nearly coincides with the frequency of the fork. Also the relation between the two auxiliary forks was *assumed*, and not determined; but as to this there can be no doubt, unless it be supposed that König's scale may be in error to the extent of a whole tone.

RAYLEIGH

A NEW CONDENSING HYGROMETER

A NEW apparatus of this kind, invented by M. Alluard, and described by him in *La Nature*, is distinguished from all those hitherto employed by the two following points:—(1) The part on which the deposit of dew is to be observed is a plane well-polished face A, of silver or gilt brass; (2) This plane face is set in a plate of silver or brass V, itself gilt and polished, which does not touch it, and which, never being cooled, always preserves its brightness. It results from this arrangement that the deposit of dew is observed with the greatest facility, in such a manner that there is scarcely any difference between the temperatures of the instants when the dew commences and ceases to appear on the instrument properly cooled by the evaporation of ether.



Alluard's Condensing Hygrometer.

The form of the instrument is that of an upright prism with square base. Its height is eight centimetres and the side of its base eighteen millimetres. Three small copper tubes pass through the upper lid; the first reaches the bottom, and the two others, one surmounted by a funnel for introducing the ether, open only above. Two small windows enable us to judge of the agitation of the ether by the aspiration or driving back of the air intended to produce coolness by the evaporation of the volatile liquid; it is best to work with an aspirator, the aspiration of which we can regulate as we wish. A central tube permits the introduction of a thermometer, *t*, which, placed in the middle of the evaporating liquid, gives the temperature at which the deposit of dew occurs. A small sling thermometer, fixed on the side of a brass support, enables us to determine with precision the temperature of the air whose hygrometric condition we wish to ascertain.

Daniell's condensing hygrometer was formerly modified by M. V. Regnault. He made it an instrument of precision; but his apparatus has not been much used on account of its delicate construction. The deposit of dew, being made on a cylinder of polished silver, is difficult to observe. In the plane face hygrometer of M. Alluard this deposit is very easily seen by contrast, even at some metres distance, especially if care is taken to observe in such a manner as to avoid all reflection from the gilt faces, when they will appear a beautiful ebony black. Its employment being very simple, without losing anything of its precision, there is no reason why it should not come into general use.

Since meteorological observations have multiplied on all sides, the hygrometer has assumed an importance which it had not before. The psychrometer is at present almost exclusively employed. But all physicists know that below zero we cannot trust the results which it gives; it is the same when the air is much disturbed. And yet, almost everywhere, it continues to be employed on these conditions. We hope that the plane face hygrometer, furnished during the winter cold with an aspirator filled with glycerine, will be able to yield accurate results to all who do not fear to devote a few minutes to its working.

OUR ASTRONOMICAL COLUMN

EARLY OBSERVATIONS OF THE SOLAR CORONA.—Referring to Mr. Dreyer's letter in NATURE (vol. xvi. p. 549), the note in this column relating to the solar eclipse of 1605 was by no means intended to imply that it afforded one of the earliest observations of the corona, nor can the eclipse of Stiklastad, as it has been usually called, on August 31, 1030, be so characterised. Prof. Julius Schmidt, of Athens, had called attention in 1870 to a record of the eclipse of December 22, 968, in Corfu, where he found a reference to the corona, but a much earlier date is assigned by Prof. Grant for the first mention of this phenomenon. It occurs in Philostratus' "Life of Apollonius of Tyana," Book VIII., chap. xxiii., in the Leipzic edition, and runs thus:—*Περὶ δὲ τὸν χρόνον, ὃν ἐν τῇ 'Ελλάδι ἐνεσπούδαζεν, ἐπεῖχε τὸν οὐρανὸν διοσημία τοιαύτη. τὸν τοῦ 'Ηλίου κύκλον περιελθῶν στέφανος, ἐοικως ''Ιριδι, τὴν ἀκτῖνα ἠμαυροῦ.* Prof. Grant considers that "the words here quoted refer beyond all doubt to a total eclipse of the sun, and that the phenomenon seen encompassing the sun's disc was really as well as verbally, identical with the modern corona." He also points out that Plutarch, who was contemporary with Apollonius, refers to a total eclipse of the sun which had *recently* occurred, and remarks of total solar eclipses in general that "a certain effulgence is seen round the circumference," so that although the sun may be wholly covered by the moon "still the eclipse is deficient in duration as well as in amplitude," this surrounding effulgence not allowing of a very intense shadow. These remarks of Philostratus and Plutarch Prof. Grant thinks may probably apply to the same eclipse, and afford "the earliest allusions to the corona recorded in history." Several attempts have been made to discover the date of the phenomenon, but so far as we know without success.

The earliest distinct and more accurate account of the corona is that given by MM. Plantade and Capiés, who observed at Montpellier on the occasion of the eclipse of May 12, 1706.

The Outer Satellite of Mars.—Our ephemeris of the satellite of Mars is here continued ten days further from the elements employed last week, though much greater difficulty must now attend observations than when the discovery was first announced. In the middle of August the distance of the planet from the earth was less than 0·4; on November 12 it will have increased to 0·68. At the next opposition in 1879, the least distance of Mars will be 0·482, at a north declination of upwards of 18°, so that observations may be made at many observatories in this hemisphere, probably without greater difficulty than about the late opposition; at the following one in December, 1881, the planet will attain a declination of 27° N., but its distance from the earth will be at no time less than 0·602.

Prof. Asaph Hall's complete discussion of the observations of the satellites of Mars, made in the present year, will be looked for with much interest; it is only fitting that this investigation should be left in the hands of their discoverer, who has made the year 1877 a very notable epoch in the history of practical astronomy.

The following positions of the outer satellite are for 8h. G.M.T.

Nov.	3 ...	Pos.	358° ..	Dist.	21″	Nov.	8 ..	Pos.	27° ...	Dist.	25″

De Vico's Comet of Short Period.—The year to which we drew attention some time since (1876·9-1877·9) as one which might possibly witness the re-discovery of De Vico's comet of 1844 is drawing to a close without its having been remarked, and the chance of detecting it at this season if the perihelion passage be not already passed, is small. We must therefore probably place the comet in the class which, though undoubtedly moving in elliptical orbits of small dimensions when under observation, are now "lost." Whether in the case of De Vico's comet this arises from a larger error in the determination of the mean motion in 1844 than at present appears admissible, or whether the action of the planet Mars, to which allusion has been made in this column, may explain it, or again, whether the comet has encountered one of the minor planets, and thereby been deflected or disintegrated, cannot be at present ascertained. It was hardly to have been anticipated that the laborious investigations of Prof. Brünnow relating to the motion of this comet from 1844-55 would not have resulted in its re-observation.

METEOROLOGICAL NOTES

Mean Atmospheric Pressure of Europe.—A great contribution to this very important subject has been made by Dr. Buys Ballot in the second volume of the "Nederlandsch Meteorologisch Jaarboek voor 1872," which has just been published. The first 130 pages of the volume are occupied with a very careful and in certain directions exhaustive discussion of the barometric observations made at about 110 places situated in different parts of Europe from 1774 to 1874. The method of discussion is identical with that adopted by Dr. Buys Ballot in his recently published paper on the Meteorology of Holland (Nature, vol. xvi. p. 89). This method consists in accepting as the normal mean atmospheric pressure at Greenwich, Vienna, and Palermo, the arithmetic means of the observations made at these places which embrace periods of 100, 101, and 84 years respectively. The normal values for the other stations have been determined by the process of differentiation, that is, by a comparison of the means of all the observations made at the place with the corresponding means of one or more places at the nearest available stations whose normals have been already determined, and thereafter applying the necessary correction. Thus the normals which have been arrived at in this very laborious manner are substantially the averages which would have been obtained if the observations at each of the stations had been made during precisely the same terms of years. The thirty years' averages should probably have been accepted as the best normals for Stykkisholm in Iceland, instead of correcting these averages from the Greenwich and Christiania observations, seeing that a low average barometer at Stykkisholm is frequently coincident with a high barometer at either or both of these stations, and *vice versâ*. The resulting differences, however, are but slight. This work of Dr. Buys Ballot, particularly when looked at with reference to future discussions, may be said to take a place at once as a classic of meteorology. The next step to be taken in this field of European meteorology is the discussion of all good barometric observations made in Europe during the meteorological lustrum ending with 1875. To the results of this discussion corrections could be applied from Du Buys Ballot's normals, which are sufficiently numerous for the purpose, and thus a graphic representation could be made of the closest possible approximation to the true mean atmospheric pressure of Europe. In this way, by disclosing the striking, and in a large measure still unrecognised, influence of large masses of land and water on the barometric pressure, much light would be thrown on the origin and history of those great atmospheric currents which, flowing or sweeping over this continent, are mainly instrumental in determining the climates of its different regions.

Meteorology of New York, U.S. The "Annual Report of the New York Meteorological Observatory for 1876" gives, in addition to the individual observations made daily, and their monthly and annual averages, a more than usually full statement of rain and wind observations. On pp. 39-88 are given the details of the amount of rain and snow-water which fell each hour from 1870 to 1876, together with the hourly averages of each month for these seven years. These hourly means show maximum amounts during winter, from 11 A.M. to 3 P.M.; during spring, from 9 P.M. to 1 A.M.; during summer, from 5 to 10 P.M.; and during autumn, from 3 to 8 A.M. The irregularity of these periods and the irregular occurrence of secondary maxima indicate that seven years is too short a time for the determination of the hourly curve of the rainfall at New York. There appears, however, a tendency to a double maximum varying considerably with season. Extended observation alone can give this curve. The influence of the daily fluctuation of temperature and of the sea breeze which sets in very decidedly from south-east during the hot months on the rain-curve, can then be studied. During the same seven years the duration of each shower has been noted in the number of minutes, the average result of which is that the minimum time of fall, a small fraction less than two days, occurred in June; from this time it slowly but steadily rose to 3 days

17 hours in January, fell a little in February, and rose to 4⅓ days, the annual maximum in March, from which it rapidly declined to the minimum in June. On a mean of the past forty-one years the monthly averages are in excess from May to August inclusive, August and May being decidedly the months of maximum rainfall, whilst January and February are the months of least rainfall. From 1836 the annual amounts show with some interruptions a decided increase in the rainfall up to 1868, since which year there has been as decided a decrease. This result is generally corroborated by the rainfall at Washington, Philadelphia, and Providence, which Mr. Draper adds to his Report. A valuable table of the monthly amounts from 1836 to 1876 is printed at p. 6. In accordance with the suggestion thrown out by Mr. Hill (NATURE, vol. xvi. p. 505) the amounts for the winter months have been picked out, averaged for the eleven-years sun-spot period, and bloxamed. The results, thus worked out, are in inches these, beginning with the first year of the cycle :—22·57, 22·26, 22·92, 23·31, 22·24, 21·03, 21·98, 21·05, 21·14, 22·18, and 23·56.

METEOROLOGY IN RUSSIA.—The St. Petersburg Agronomical Society has appointed a special committee for the purpose of elaborating, in accord with other Russian scientific bodies, a scheme for establishing throughout Russia an extensive network of meteorological stations. Owing to the interest manifested in the subject by a great number of agriculturists, it is expected that the plan will soon be put into execution.

WE much regret to have to announce the death, on Sunday last, of Mr. Robert Swinhoe, F.R.S., a naturalist whose numerous contributions to our knowledge of the mammalia and birds of the Chinese Empire have proved invaluable to zoological science. We hope, next week, to give an account of Mr. Swinhoe's work.

THE International Committee for the erection of a monument to Liebig at Munich, having now at their disposal a sum of 120,000 marks, invite sculptors of all nations to send in models for their acceptance. A prize of 2,000 marks will be given to the model which takes the first place, and 1,500 to the second. The model of the statue should be forty centimetres, and of statue and pedestal about one metre in height. Models should be addressed to the "Castellan der königlichen Akademie der Kunste, 38, Unter den Linden, Berlin," where they will be received from June 1 to 15, 1878, to be exhibited first at Berlin and then at Munich. The Committee bear all the expenses of transport.

IT has been noted in the French papers *à propos* of the recent colliery explosion, that M. Leverrier, when presiding at the meeting of the French learned societies at Easter, proposed to extend the telegraphic warnings of the International Meteorological System to the several French pits. The question of the illumination of mines by electricity has been revived by these terrible tragedies, and a number of interesting communications connected with that important topic will be presented and fully discussed at the next meeting of the French Academy of Sciences.

IT was stated by one of the speakers at the last quarterly meeting of the French Academies that M. Thiers had written a complete work on Spherical Trigonometry when quite a young man.

WE regret to record the death of M. Cazin, Professor of Physics at one of the Paris Lycées, and an active member of the Paris Physical Society. M. Cazin was sent to the Island of St. Paul by the Academy of Sciences under the command of Capt. Mouchez to make physical observations during the last transit of Venus; he there contracted the germ of the illness which has proved fatal at the early age of forty years. He had been admitted to the Observatory by M. Leverrier to execute a series of delicate researches on magnetism, which have been left unfinished.

THE Harveian Oration at the Royal College of Physicians of London will be delivered in 1878 by Dr. J. Burdon Sanderson, F.R.S.

AN anthropological exhibition will be opened at Moscow in 1879, in connection with the society of Friends of Natural Science. Many objects of great scientific value, almost exclusively of Russian origin, are already in the hands of the organising committee.

MR. TUCKWELL, recently head-master of Taunton College School, has issued a circular addressed to head-masters, giving an account of his connection with the school whose reputation he did so much to raise, and which has treated him so ungratefully. Our readers are already familiar with the details of this unhappy matter, and we are sure will all wish with us that Mr. Tuckwell may soon find a field for the exercise of his powers as a successful teacher unfettered by the narrowness of uneducated and narrow-minded directors. Mr. Tuckwell gave Taunton School a status and a name; the Council of the school have undone all his work, and left the school nowhere.

THE winter session of the Chester Society of Natural Science opened on October 25 with a lecture on "The Arctic Regions," by Mr. de Rance, of H.M. Geological Survey. The upper silurian, lower carboniferous sandstones, mountain limestone, and lias of the Parry Archipelago, as well as the oolites, cretaceous and miocene rocks of Greenland and Grinnel Land, were described as occupying hollows in the old Laurentian Mountains, and the existing cold climate was stated to have probably only prevailed since the last glacial epoch. The range of the northern mammals, and the discovery of remains of the Eskimo by Capt. Feilden, R.N., naturalist of the *Alert*, near Cape Beechey, far north of the present limit of human habitation, and further north than any previous discovery of man or his works, were commented on; and a large collection of Arctic fossils were exhibited by Sir Phillip Egerton, collected in Grinnel Land by his nephew, Lieut. Egerton, R.N., of the late British Arctic Expedition.

AN unusually interesting scientific *soirée* was recently held at the Bristol Museum and Library, which has been characterised as "the headquarters of scientific research in the west of England." Many of the most recent scientific experiments were shown, the most attractive probably being Prof. Graham Bell's exhibition of the wonders of the telephone. During the winter a course of lectures has been arranged for at the museum, mostly scientific, as follows :—November 19—A. R. Wallace, F.R.G.S., F.L.S., the Distribution of Animals as indicating Geographical Changes; November 29—Prof. Ball, F.R.S., a Night at Lord Rosse's Telescope, illustrated by the Oxy-hydrogen Lantern. December 10—Frederick Wedmore, Rembrandt; his Life and Work. January 14—Prof. Marshall, M.A., Principal of University College, Bristol, The Economic Condition of America. January 28—Prof. W. C. Williamson, F.R.S., Coal and Coal Plants. February 11—C. T. Hudson, M.A., LL.D., The Larger and Rarer Rotifers; illustrated with Transparent Diagrams. February 26—Prof. Rowley, M.A., of University College, Bristol, Francis Bacon: his Personal Character and Political Career. March 11—Dr. J. H. Gladstone, F.R.S., Fiery Meteors and Meteoric Stones. March 25—J. Norman Lockyer, F.R.S., Sun Spots in Relation to Indian Famines, with Spectroscopic Experiments and Oxy-hydrogen Lantern Illustrations.

The Royal Society of New South Wales, originated in 1821 as the Philosophical Society of Australia; after an interval of repose it was revived in 1850 as the Australian Philosophical Society, by which designation it was known until 1856, when the name was again changed to that of the Philosophical Society of New South Wales, and finally, about ten years ago, by the sanction of her Majesty the Queen, it assumed its present title. Judging by its present list of members it would seem to be prospering, but judging from the volume of its *Proceedings* (vol. x. for 1876) its scientific life might be higher, and we would venture to express the hope that future volumes may give us a larger number of memoirs treating of that vast quadrilateral of which Sydney is the acknowledged capital. Of the articles in this volume we would notice the following: On the Deep Oceanic Depression off Moreton Bay, by the Rev. W. B. Clarke, F.R.S.; On some Tertiary Australian Polyzoa, by the Rev. J. E. T. Woods. The species were with one exception derived from the Mount Gambier polyzoan limestone, South Australia, and are all described as new; ten are described and figured as belonging to the genus Eschara, two species of the genus Pustulipora are described, and one Tubulipora. On the formation of Moss Gold and Silver, and on a Fossiliferous Siliceous Deposit from Richmond River, is the title of a paper by Prof. Liversidge. The composition of this deposit shows that it answers to the common siliceous sinters or geyser deposits. The weathered surfaces are usually marked with the remains of ferns which stand out in relief, and more rarely through the mass are to be found the remains of certain fruits and seeds. These latter have been described by Baron Muller as belonging to a plant (*Liversidgea oxyspora*) allied to Capparideæ and Bixaceæ, the fruits are from two-thirds to nearly an inch in diameter, divided into four turgid lobes, placentas parietal; seeds turgid; oval towards one extremity and attenuated at the other; both fern and fruits are figured. In the discussion following the reading of a paper by the Rev. W. B. Clarke, F.R.S., On the Effects of Forest Vegetation on Climate, many interesting statements were made as to the condition of the forests in the neighbourhood of Sydney at the present time, and so long back as forty years ago.

Petermann's *Mittheilungen* for November contains a paper by Dr. G. Radde describing the journey of himself and Dr. Sievers from Erzeroum to the Bin-Gol-Dagh; the paper is full of details concerning the botany of the region traversed. Under the title of "Tekna and Nun," Dr. Rohlfs gives some valuable information on the part of the Sahara about the south-west of Morocco, showing that it is by no means so barren as is generally thought, and that even the most recent maps of the region are unsatisfactory.

One of the most interesting papers in the September number of the *Bulletin* of the French Geographical Society is an account by M. Brau de St.-Pol-Lias of his visit to the French Colonial stations recently established on the coast of Sumatra, in the province of Deli. The author gives many interesting observations on the people and the products of the part of the island which he visited, and speaks hopefully of the colony, which he considers an excellent basis for the exploration of the island. In the same number Dr. Harmand gives some account of recent journeys he made in Cambodia.

The first map showing the whole of Stanley's route from Bogomayo to the mouth of the Congo has been published by *L'Exploration* (October 21). In this map the course of the Congo is roughly shown as indicated in Stanley's letter, and that also of the Ogové according to the explorations of de Brazza, Lenz, and Marche. The trend of the Ogové to the south-east is shown, and its probable junction with the Congo by two arms indicated.

The Geographical Society of Paris has received letters from the French Consul at Zanzibar informing them that a road is being opened from Zanzibar to Tanganyika, for carting by oxen. It is expected that ere long explorers will be able to dispense with native porters.

A Geographical paper has been started at Lyons by M. du Mazet, one of the staff of the *Courrier de Lyon*. It will record the transactions of all the provincial geographical societies of France. The Lyons Geographical Society will have the advantage of a number of communications from the Roman Catholic missionaries who have an old-established special seminary and college in that city.

In the *Times* of Wednesday last week appeared a long story about the discovery of the remains of Columbus in St. Domingo. At Madrid, the *Times* Paris correspondent now states, the story is declared to be a hoax, inasmuch as "a Spanish squadron years ago escorted the remains to Havannah, where they lie in the Cathedral."

Under the title of "Pictorial Geography for Young People," Messrs Griffith and Farran have published a neat little map intended to exhibit graphically the significance of the various terms used in geography—continent, island, river, lake, mountain, volcano, city, &c. It is necessarily exaggerated, but in the hands of a judicious teacher might be a valuable and attractive help to the teaching of the elements of geography.

Two severe shocks of earthquake were experienced at Lisbon at 6.45 A.M. of October 25. No damage was reported.

Under date October 17, it is reported from Smyrna, in Asia Minor, that there had been, during a few days, several earthquake shocks doing no further harm but cracking some walls.

It has been affirmed by P. Secchi of Rome, that iron heated red is transparent to light. This is denied by M. Govi of Turin, who, in a paper to the French Academy, describes some experiments on the subject, and shows how one may be deceived in studying the phenomena. If a mixture of borax and carbonate of soda be fused in a thin platinum crucible raised to a red heat, there will be seen on the exterior of the vessel the form of the liquid mass with all its accidents of rapidly varying form, indicated by a zone of less brightness than the upper portion of the metallic surface. At first sight it is natural to infer a transparence for light of the heated platinum, but (M. Govi points out) the case is really one of transparence for radiant heat; that is to say, a phenomenon connected with the good conductivity of platinum. The liquid, liberating carbonic acid, is less hot than the crucible, and is constantly borrowing heat from it. It is inevitable, then, that at every point where the liquid touches the metal, the latter relatively cooled, should appear less luminous than in the neighbouring region. M. Govi gives some other examples of the phenomenon.

"Shorthand for General Use" is the title of a little volume by Prof. Everett, of Belfast, published by Marcus Ward and Co. Prof. Everett's system claims several advantages over Pitman's, one being that the vowels can be written continuously with the consonants, and thus the word has not to be gone over a second time to insert the vowels. The system appears to us decidedly worth the attention of anyone wishing to learn shorthand.

We have received the eighth edition of Prof. Atkinson's translation of Ganot's "Physics." About sixty pages of additional matter, with an equal number of illustrations, have been added to this edition. Messrs. Longmans and Co. are the publishers.

Another scientific play is now being performed at the Cluny Theatre, Paris, under the title of the "Les 6 Parties du Monde." It is written by M. Figuier, the well-known scientific story-teller. The sixth part of the world is supposed to be the Antarctic continent, where Dumont Durville is made to land. It is a masterly panorama of a number of climes and countries, enlivened by a well-constructed plot.

DR. HOEK, of Leyden, sends us the following additions to the list of dealers in zoological specimens given by Prof. Ray Lankester in a recent number of NATURE :—1. Hilmar Lührs, Fischer f. Zoologen und Aquarien, Helgoland (Unterland), for fish and invertebrates (alive and in spirits, specimens of all classes). 2. The Zoological Station of Dr. Anton Dohrn, Naples, for fish and invertebrates (spirit specimens).

THE additions to the Zoological Society's Gardens during the past week include three Tigers (*Felis tigris*), born in the Gardens, but did not survive; a Common Genet (*Genetta vulgaris*) from North Africa, presented by Mr. P. V. Carletti; two Hyacinthine Porphyrios (*Porphyrio hyacinthinus*) from West Asia, presented by Mrs. Henry Cobb; two All-Green Parakeets (*Brotogerys tiriacula*) from South America, presented by Miss Rowe; two Yellow-bellied Liothrix (*Liothrix luteus*) from India, presented by Gen. Beeton; two common Marmosets (*Hapale jacchus*) from South-east Brazil, presented by Mrs. Clayton; three Darwin's Pucras (*Pucrasia darwini*), a Chinese Blue Magpie (*Urocissa sinensis*) from China, a Sun Bittern (*Eurypyga helias*) from South America, deposited; a Moose (*Alces machlis*) from North America, purchased.

AMERICAN SCIENCE

PROF. HENRY'S portion of the report of the Smithsonian Institution for the year 1876 has been printed in separate pamphlet form, in advance of the entire volume, and gives the usual record of operations for the period. It draws attention to the fact that it is the thirtieth of the annual series made by him, and that the policy advised at the first meeting of the board has been carried out with scarcely any modification. The original fund of 541,379 dols. has been increased to 714,000 dols., although a building costing nearly 500,000 dols. has been erected. There is a library of 70,000 volumes of the most valuable class of books, namely, the serial scientific publications of learned societies. The museum has grown until it now ranks among the best in existence. This embraces copious collections illustrating the ethnology and natural history of the world. The institution has published twenty-one quarto and forty-two octavo volumes of transactions and reports. It has carried on successfully a great system of meteorological observations (only intermitted on the successful operations of the Signal Service), the results of which have been issued by a number of stately volumes. It is now prosecuting a great system of international exchanges, for the benefit of the whole world. Its correspondence, both at home and abroad, requires a large number of clerks and specialists; and the name of Smithson is universally known in consequence.

Details have been recently published (*Proc.* Acad. Nat. Sci. Philadelphia, 1877, p. 255) of the exploration of a specially interesting mound at Coup's Creek, Macoupin County, Illinois. Four skeletons sat within it, considerably enveloped in a peculiar granulated but exceedingly tenacious earth. They were placed two and two, their arms crossed, the knees of one pair pressing sharply against the backs of the other, and the faces of all turned directly toward the east. Though the greatest care was taken, only one skull was removed comparatively perfect. The whole grave measured but six feet in length by three in width, and it contained in addition to the skeletons four large marine shells of *Pyrula* (*Busycon*) *perversa* (Lam.), each similarly placed in relation to the bodies. The smaller end of one shell was placed in the right hand of each individual, while the larger portion rested in the hollow above the left hip. But, still more remarkable, within each shell had been packed what appeared to be the bones of a child; the skull, crushed before burial, protruded beyond the aperture. The suggestion is made that these infants were sacrificial offerings in honour of the dead. The graves in these mounds are constructed of stone slabs from the locality, and hence they are known as stone graves. The builders give evidence of decided constructive ability, and of having been careful cultivators of the soil. The grave-mounds are found upon ridges, while others on which dwellings were supported are near streams. A systematic series of mounds of similar origin extends from the foot of Lake Michigan to the mouth of the Illinois river, a distance of two hundred and fifty miles. Unfortunately the remains are scarcely ever capable of being preserved, or even of being examined satisfactorily on exhumation.

The following are notes of papers in the October number of the *American Journal of Science and Arts* :—The nickel plates now largely used as anodes for nickel plating are prepared by fusing commercial nickel, generally with addition of charcoal, and casting in suitable form. From an analysis of several specimens of cast nickel by Mr. Gard, it appears that silica may be reduced and retained as silicon, and that a considerable amount of carbon may be present (*e.g.*, 1·9 and 1·8 per cent.). One experiment made with a view to ascertain how much carbon nickel may take up under conditions to which it is more or less exposed in the processes of manufacture and casting, was to pack half-a-pound of granular commercial nickel in layers with charcoal in a Hessian crucible, in which it was exposed to a full red-heat twelve hours. No fusion took place. The temperature was then raised till there was complete fusion. The resulting metal was strongly magnetic, quite soft, and to a considerable extent malleable. Its specific gravity was 8·04, and it had a fracture like that of fine-grained pig-iron, scales of graphite being plainly visible. It was found to contain of total carbon 2·105, 2·130; graphitic carbon, 2,030, 1·990; silicon, ·360. Mr. Gard also made some experiments on the deportment of nickel and cobalt towards hydrocarbon at a high temperature, the substances being placed in a platinum trough within a porcelain tube and treated with a slow current of pure dry marsh-gas at a full red heat. In one case thin plates of pure electroplate nickel (·8597 gr.) were found at the close to have gained 10·649 per cent.; in another 1·2697 gr. of cobalt gained 12·758 per cent.

Among other chemical contributions we note one on the iodates of cobalt and nickel, by Mr. Fullarton, who finds that the true normal iodates contain really six molecules of water of crystallisation, and that they are essentially different from the salts obtained by Rammelsberg. Several specific-gravity determinations follow (by students of Cincinnati University), including those of a series of chromates, by Miss Abbot. Pettersson has lately shown that selenates have molecular volumes exceeding those of the corresponding sulphates by six for each molecule of the acid radicle. On comparing the chromates with Pettersson's selenates, it is found that the two series of salts have approximately equal molecular volumes; the difference, if any exists, being very slightly plus for the selenates. If regularities of this kind can be thoroughly established, it will be easy (Prof. Clark suggests), having the density of a chromate, to calculate that of the corresponding sulphate or selenate, or *vice versâ*.

A preliminary catalogue of the reptiles, fishes, and Leptocardians of the Bermudas is furnished by Mr. Brown Goode, comprising 148 out of 163 known species. The Bermudan fauna shares with the West Indies 116 species (or 79 per cent.), of which 58 (or 40 per cent.) are peculiar to the West Indies, while many others have their centres of distribution in that region. With the Eastern United States Bermuda shares 47 species, and with the waters of the Pacific and Indian Ocean 32 species. Mr. Goode also gives a description of four species of fishes believed to be new.

Prof. Dana draws some lithological and orographic conclusions in his (continued) paper on the relations of the geology of Vermont to that of Berkshire, and the *Journal* also contains some information on the Archæan of Canada and the geology of New Hampshire, &c.

THE EARTHWORM IN RELATION TO THE FERTILITY OF THE GROUND

FROM observations extending over a number of years, M. Hensen is led to the conclusion that infertile undersoil is rendered valuable by the action of worms in two ways, viz., by the opening of passages for the roots into the deeper parts, and by the lining of these passages with humus. This will be more fully understood from the following facts regarding the life-habits of the worm (*Lumbricus terrestris*) given in M. Hensen's paper in the *Zeitschrift fur wissenschaftliche Zoologie*.

It is known that the adult animals in wet weather come up to the surface by night, and, with their hinder end in their tube, search the ground round about. They then draw whatever vegetable material they can find into their tubes—fallen stems and leaves and small branches. In the morning one then finds little heaps of plant-fragments projecting at various parts of the surface, and each of them penetrating the tube of a worm. On closer examination it is found that the leaves have each been rolled together by the worm, and then drawn into the tube in such a way that the leaf-stalk projects. The portion of the leaf in the tube is moist and softened, and only in this state are plants consumed by the worm. There are distinct indications that the worm gnaws them, and after some days the meal is ended. The food is never drawn deeper down into the ground. In digging the ground at various seasons it was only very rarely that plant remains were found in the subsoil, and probably they got there by accident.

With reference to the structure of the worm-tubes, some interesting facts were established in these researches. In humus their character is difficult to make out, owing to the looseness of the mass. In sand they proceed almost vertically downwards three, four, or even six feet, whereupon they often extend some distance horizontally; more frequently, however, they terminate without bending. At the end of the tube the worm is found with his head upwards, while round about him the tube is lined with small stones. On the sandy wall of the tube one observes more or less numerous black protuberances which make the sand fertile. These are the secretions of the worm, which, after being removed out of a tenanted tube, are found next morning replaced by fresh matter. They are observed after a few days, when a worm is put in a vessel with clean sand, and allowed to make a tube for itself. Older abandoned tubes are pretty regularly lined with the earth formed by the worm, and some passages are densely filled with black earth. This black substance appears to diffuse somewhat into the sand.

In about half of the tubes, not quite newly made, M. Hensen found roots of the plants growing at the surface, in the most vigorous development, running to the end of the tube and giving off fine root-hairs to the walls, especially beautiful in the case of leafy vegetables and corn. Indeed such tubes must be very favourable to the growth of the roots. Once a root-fibre has reached such a tube it can, following the direction of gravity, grow on in the moist air of the passage, without meeting with the least resistance, and it finds moist, loose, fertile earth in abundance.

The question whether all roots found in the under-soil have originally grown in the tubes of worms, cannot be answered with certainty. It is certain that the roots of some plants penetrate themselves in the sand, but not to great depths. M. Hensen is of opinion that the tap-roots, and in general such root-forms as grow with a thick point, can force a path for themselves, while the fine and flexible suction-roots have difficulty in obtaining a path into the depths other than what has been previously made for them. Roots of one year's growth especially can penetrate deep into the sub-soil, only where there are earth-worms.

A microscopical comparison of the earth deposited by the worm shows that it is like the two-year leaf-mould prepared by gardeners for the filling of flower-pots. Most of the plant-cells are destroyed; still there are present some cells and shreds of tissue, browned and friable, mixed with many sand grains and brown organic fragments. The chemical composition of the worm-earth shows much similarity to that of fertile humus ground. Its fertility, therefore, cannot be doubted, though direct experiments with it are wanting.

With regard to the numerical value of this action of the earthworm, the following observations by M. Hensen afford some information.

Two worms were put into a glass pot 1½ foot in diameter, which was filled with sand to the height of 1½ foot, and the surface covered with a layer of fallen leaves. The worms were quickly at work, and after 1½ month many leaves were down 3 inches deep into the tubes; the surface was completely covered with humus 1 cm. in height, and in the sand were numerous worm-tubes partly fresh, partly with a humus wall 3 mm. thick, partly quite filled with humus.

Counting, when an opportunity offered, the open worm-tubes in his garden, M. Hensen found at least nine in the square foot. In 0·15 square metres two or three worms were found in the deeper parts each weighing three grammes: thus in the hectare there would be 133,000 worms with 400 kilos. weight. The weight of the secretions of a worm in twenty-four hours was 0·5 grammes. While these numbers are valid only for the locality referred to, they yet give an idea of the action of this worm in all places where it occurs.

The assertion that the earthworms gnaw roots is not proved by any fact; roots gnawed by worms were never met with, and the contents of the intestine of the worms never included fresh pieces of plants. The experience of gardeners that the earthworm injures pot plants may be based on the uncovering or mechanical tearing of the roots.

"Let us take a retrospective glance," concludes the author, "over the action of the worm in relation to the fertility of the ground. It is clear that no new manure material can be produced by it, but it utilises that which is present in various ways. 1. It tends to effect a regular distribution of the natural manure material of fields, inasmuch as it removes leaves and loose plants from the force of the wind and fixes them. 2. It accelerates the transformation of this material. 3. It distributes it through the ground. 4. It opens up the undersoil for the plant roots. 5. It makes this fertile.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

Oxford.—The University Commissioners are at present occupied in taking evidence on the subject of University requirements. The Dean of Christ Church, the Master of Balliol, the Master of University, the Librarian of the Bodleian, Profs. Clifton, Bonamy Price, Bartholomew Price, Stubbs, and others have appeared, or are to appear during the present week, before the Commissioners.

Mr. Lazarus Fletcher, B.A., of Balliol, has been elected to the vacant Fellowship at University College. Mr. Fletcher obtained a first class in the School of Mathematics in 1875, a first class in that of Natural Science in 1876, and the senior mathematical scholarship in 1876.

It is proposed to found a high school for the City of Oxford, the mayor, aldermen, and citizens having long felt it a reproach that, being the site of one of the most ancient and famous of the Universities of Europe, it has been absolutely without any recognised grammar school available for the sons of the citizens.

London.—Prof. W. K. Clifford, F.R.S., is at present delivering at University College a very interesting course of Lectures on Quaternions. The main object of the course is to bring the physical applications of quaternions as much as possible within the reach of mathematicians of moderate attainments.

A requisition is in course of signature to the chairman of Convocation of London University, Dr. Storrar, asking that an extraordinary meeting of that body may be convened for the purpose of considering and discussing the following resolutions, and for deciding with reference thereto in such manner as to Convocation may seem fit:—"That it being manifestly inexpedient that frequent application should be made to the Crown for new and additional charters, it is desirable that provision should be made in any such charter for all changes in the constitution of the University, either at the time urgent or likely to be soon required; and that it being probable that initiative measures will be shortly taken towards procuring such a new or additional charter, the following proposals require the serious consideration of Convocation and the Senate:—'(1) An enlargement of the powers directly exercised by Convocation; (2) An increase in the proportion of senators to be nominated or elected by Convocation, and the limitation of the tenure of office in the case of all senators to a term of years; (3) The encouragement of mature study and original research among the members of the University, by the establishment of University lectureships, of limited tenure, in different departments of learning and science; (4) The introduction into the constitution of the University of such modifications as may remove all reasonable ground of complaint, on the part of any of the affiliated colleges, with respect to the absence of means for expressing opinion and giving advice to the Senate on the examination regulations, and on the changes proposed to be made therein from time to time. And that a Special Committee of ten members of Convocation be appointed to consider the above-mentioned proposals, and to report thereon to Convocation as speedily as possible.'"

The Entrance Science Scholarships in St. Thomas's Hospital have been awarded this year as follows:—The Scholarship of 60*l*. to Mr. Wansborough Jones, B.A. Oxon., and B.Sc., London; and that of 40*l*. to Mr. A. E. Wells.

BRISTOL.—A well-printed and well-arranged Calendar of University College has been published. It extends to upwards of sixty pages, and contains all the information usually found in such publications, including full details as to the Medical School.

Dean Stanley's address on Education, at University College, on Saturday, attracted an audience of about 1,700 people, who listened with the closest attention.

SCIENTIFIC SERIALS

Kosmos, Part 2 (May) opens with an article by L. Overzier, on "Heredity" (Part 1), aiming at the discovery of the real cause of inheritance.—Prof. Jäger, commencing a series of articles on "The Origin of Organs," deals with the development of the eye, showing how the laws of optics and the properties of living substance mutually influence one another.—Hermann Müller, treating on "The Origin of Flowers," considers the first metasperm (or angiosperm) to have been diclinous and fertilised by the wind, that is, supposing the metasperms to have originated from a single stock.—W. O. Focke deals with "The Conception of Species in the Vegetable Kingdom," especially in relation to the genus Rubus. He shows how far the different species are from being of equivalent value and that the term variety has no definite significance. He exposes the futility of much botanical "research," owing to imperfection of methods and lack of comparative study; Darwin has few imitators. Such work requires an entire devotion of time and complete botanical gardens, for the multiplication of which the author calls.—A. Lang, on Lamarck and Darwin (I.), expounds Lamarck's conceptions of natural history.

Kosmos, Part 3 (June).—L. Overzier continues his discussion of heredity, reviewing Darwin's theory of pangenesis, Haeckel's perigenesis, and Jager's chemical theory; he considers the latter to be of great value.—Carl du Prel, on the needed remodelling of the nebula hypothesis.—Prof. Jager treats of the origin of the organ of hearing, tracing it from the simplest condition where spicules diffused through the entire protoplasmic body of an animal serve to gather up and conduct vibrations of sound. He brings forward the remarkable theory that in animals possessing nerve fibres, the organs of hearing is but a specialisation from the general tactile sense.—W. von Reichenau, on the colours of bird's eggs, makes the generalisation that birds having open nests have coloured eggs, while those with covered or concealed nests have white ones; further, that in open and ground nests the colour of the eggs has a protective object.—A. Dodel-Port, on the lower limit of sexuality in plants, gives an account of the sexual processes in *Ulothrix zonata*, but appears not to have heard of the researches of Dallinger and Drysdale on the monads.—A. Lang, on Lamarck and Darwin, expounds Lamarck's "hydro-geology."

SOCIETIES AND ACADEMIES

PARIS

Academy of Sciences, October 22.—M. Peligot in the chair.—The following papers were read:—M. Leverrier's tables of Uranus and Neptune, by M. Tresca.—On some applications of elliptic functions (continued), by M. Hermite.—*Résumé* of a history of matter (first article), by M. Chevreul. This is an extract from a work commenced about the end of last year, and occupying 418 pages of the *Memoires de l'Académie*, t. xxxix. A sketch of the principles of alchemy is given.—On one of the causes of red coloration of the leaves of *Cissus quinquefolia*, by M. Chevreul. This cause is sunlight. The green colour is retained in the leaves that are shaded by others.—On the order of appearance of the first vessels in the shoots of some Leguminosæ, by M. Trécul.—Modifications in the conditions of maxima of electro-magnets by the state of more or less complete saturation of their magnetic core, by M. Du Moncel. The law of proportionality of the attractive forces to the squares of the intensities of the current is true only within certain limits, and under certain conditions; and electro-magnets through which the current is interrupted at very short intervals, are (more or less) not subject to it. When the forces are proportional to (say) the cubes of the electric intensities, the helices must always be less resistant than the exterior circuit. In the case of multiplied interruptions, the resistance of electro-magnets must always be less the shorter the duration of closures of the current; and for this reason (also because of defective insulation [illegible] extra currents) telegraph electricians reduce considerably the resistance of electro-magnets applied to long circuits. Reverting to the question in the title, the thickness of the magnetising spiral may be increased in case of defective saturation of the magnetic core; becoming double the diameter of this if the force increases as the cube of the intensities.—Preparations of sulphide of carbon brought to the solid state by means of gelatine, by M. Cassius. 100 grammes of gelatine are dissolved in 1,000 grammes of water, and sulphide of carbon (25, 50, or 75 per cent.) is mixed at a temperature of 15° to 20°, and the mixture let cool. M. Cassius thinks the preparation might be useful in viticulture. The sulphide is liberated slowly, the time varying according to the proportion of sulphide absorbed.—Experiments on the formation of artificial ultramarine, by M. Plicque. He finds (in opposition to some German authors) that ultramarine does not contain nitrogen. Blue ultramarine, properly so called, is formed by an oxygenated compound of sulphur, and it is probable that this compound is fixed both by sodium and by aluminium.—On the catechines and their constitution, by M. Gautier.—On acid acetates, by M. Villiers. The increase of weight of some neutral acetates, dried and placed, in a summer month, under a bell jar with crystallisable acetic acid, was, in the case of acetate of soda, 404 per cent., or nearly six equivalents of acetic acid; acetate of potash, 264 per cent; of baryta, 179 per cent.; of lead, 134 per cent, &c. The solutions of neutral acetates in crystallisable acetic acid have much less tension of vapour than that of acetic acid.—Researches on butylene and its derivatives, by M. Puchot.—Note on the cause of anthrax, by M. Klebs.—On the structure of the blood corpuscle, and the resistance of its envelope to the action of water, by MM. J. Bechamp and Baltus. The demonstration of the membrane (by action of soluble fecula) is here given in the cases of the frog, the ox, the pig, and the sheep. Water does not destroy the globules; it merely renders them invisible, and they may always be discovered with the aid of picrocarminate, even in extremely dilute media, and after several weeks of contact. The blood of sheep (like that of the hen in M. A. Bechamp's experiments) contains globules of more delicate structure than those of the other bloods examined.—Researches on the functions of leaves of the vine, by M. Macagno. Glucose and tartaric acid are formed preferably in the upper leaves of the fruit-bearing vine-branch; this production of sugar progresses with that of the grape, and is much reduced (even to disappearance) after the vintage. The green branches are conductors of glucose. These facts explain the evil of "pinching" or removing the tops of the grape-bearing branches, with too great zeal. Where there is an abundant production of grapes, a sufficient quantity of leaves should be left for preparation of the necessary glucose.—Reply to a recent note of M. Buys Ballot, on the division into time and into squares of maps of nautical meteorology, by M. Brault.

EXPLOSIONS IN MINES

AFTER the occurrence of great colliery explosions such as those which took place recently in Pemberton and Blantyre collieries, one very general and pertinent question presents itself to most minds, namely, What has been done or attempted with the view of preventing these disasters? It would be impossible to condense into an article like the present all that could be said in reply to this question, but I shall endeavour to give a brief outline of the subject, and point out, as well as I can, what appear to be its most prominent features.

Before the invention of the safety-lamp, the only means of guarding against the ignition of firedamp consisted in the employment of an apparatus called the "steel mill." The light obtained by its aid was feeble and uncertain, and Mr. Buddle informs us that explosions were known to have been caused by the sparks emitted by it. When Davy made his brilliant invention in 1815-16, the steel mill was laid aside for ever, and it was then imagined that colliery explosions had also become phenomena belonging to a past order of things. So confident, indeed, was Davy in the efficacy of his lamp, that he believed it could be safely employed for carrying on work in an explosive atmosphere; and he even went so far as to propose to make use of the firedamp itself as the light-giving combustible. These fond expectations were soon roughly dispelled, as one explosion followed another in an apparently unaccountable manner; and at length they were succeeded by a feeling of positive distrust, which found expression in the report of a select committee appointed, in 1835, to inquire into the nature of accidents in mines.

In 1850 Mr. Nicholas Wood made a series of experiments, which proved that when a Davy lamp is subjected to an explosive current travelling at the rate of eight or nine feet per second, the flame soon passes through the wire gauze. This was corroborated about 1867 by experiments conducted by a committee of the North of England Institute of Mining Engineers.

Lastly, in 1872-73, the writer demonstrated, also by experiment, that when a lamp burning in explosive gas is traversed by a violent sound-wave, such as that produced by a blasting shot, the same result follows, that is, ignition is communicated to the outside atmosphere. These are weak points inseparable from the construction of the ordinary Davy and Clanny lamps; but as it is now a thoroughly-recognised maxim that work must never, under any circumstances, be continued in an explosive atmosphere, they are seldom put to the test.

The atmosphere of part of a mine may, however, become explosive before the men can escape, either by the sudden influx of a quantity of firedamp from some natural cavity in which it had existed in a state of tension, or by a partial or total cessation of the ventilating current; and I propose in the next place to consider how such an event could produce an explosion supposing all the men to be provided with safety lamps.

This will happen, firstly, if the inflammable gas passes over a furnace at the bottom of the upcast secondly, if it is carried against a Davy or Clanny lamp at a greater velocity than seven feet per second, or if the lamp is traversed by a sound-wave; thirdly, if a blasting shot is fired directly into it; and lastly, if it reaches a safety lamp that has been opened by one of the men.

The means that have been provided for guarding against these contingencies are as follow:—1. Furnaces have to a large extent been replaced by ventilating fans in fiery collieries. 2. Davy and Clanny lamps are still almost universally employed, and little importance seems to be attached to their known imperfections by those who are supposed to be capable of deciding the question. 3. Shot-firing having been found to originate many explosions, although probably in a manner not yet understood by most people, is now carried on under certain restrictions which it could easily be shown are still insufficient. 4. Much nonsense has been talked and written about miners opening their lamps. That they sometimes do so is beyond a doubt; but why should this state of matters be allowed to continue when it can be easily put an end to? The present flimsy pretence for a lock is not a necessity but a cheap convenience; and who is responsible if say a hundred men are killed through its being opened by one? Is there no responsibility attaching to the owners or the legislature for placing the lives of ninety-nine innocent men in danger? I think surely there is.

The influence of changes of weather on the internal condition of mines has been remarked since the remotest times, and for the last fifty or sixty years at least many have asserted that firedamp is more prevalent when the barometer is low than in the opposite case. The explanation of these phenomena is easily found by anyone who has an elementary knowledge of the physical properties of gases. On the other hand, when vigorous artificial means of ventilation are employed, and ordinary skill practised in distributing the air, the effects of changes of weather become much less perceptible.

Hence if a large proportion of explosions can be shown to occur simultaneously with, and therefore, presumably, in consequence of, those atmospheric changes that would tend to augment the amount of firedamp in the workings, there is a strong argument in favour of the supposition that they are preventible, and cannot therefore be considered as accidents in the true sense of the term. With this object in view diagrams have been made from time to time by Mr. R. H. Scott and myself, and also by one or two others, showing the connection that exists between the two classes of phenomena, and an examination of these is sufficient to convince unbiased persons that there is a striking coincidence between the explosions and the favourable atmospherical conditions. As might, perhaps, be expected, some persons engaged in mining either fail to see the connection, or possibly they do not understand it. Nevertheless a general rule was inserted in the Coal Mines' Regulation Act (1872) making it compulsory for mine-owners to place a barometer and thermometer at the entrance to every mine in the coal-measures.

It has always been difficult, and sometimes impossible, for mining men to give an adequate reason for the extent of great explosions, and more especially when it is known that, immediately beforehand, little or no inflammable gas has been present in the workings. The reports of the Inspectors of Mines bear ample testimony to the correctness of this statement. It has therefore been customary in the absence of any other tenable hypothesis to assume that a large volume of firedamp had been suddenly poured into the workings. But these so-called "outbursts of gas" are entirely unknown in some localities in which great explosions have occurred; and therefore it is much to be marvelled at that some other explanation was not at least sought for.

In September, 1844, before the appointment of inspectors of mines, Lyell and Faraday were sent to Haswell Colliery by the Home Secretary to report on an explosion that had just taken place there. I am unable to quote from their official report, but I am firmly convinced that the following sentences taken from their article on the subject in the *Phil. Mag.* 1845, is the true key to a solution of the problem as regards both the mode of occurrence and means to be used for the purpose of avoiding great explosions in future; and, moreover, I believe that it has been highly unfortunate, both for the cause of the miner and his employer, that these two philosophers were not induced to prosecute their investigations further than they did.

The sentences referred to are these:—"In considering the extent of the fire for the moment of explosion, it is not to be supposed that firedamp is its only fuel; the coal-dust swept by the rush of wind and flame from the floor, roof, and walls of the works, would instantly take fire and burn, if there were oxygen enough in the air to support its combustion; and we found the dust adhering to the face of the pillars, props, and walls in the direction of, and on the side towards, the explosion, increasing gradually to a certain distance as we neared the place of ignition. This deposit was in some parts half an inch, and in others almost an inch thick;[1] it adhered together in a friable coked state; when examined with the glass it presented the fused round form of burnt coal-dust, and when examined chemically, and compared with the coal itself reduced to powder, was found deprived of the greater portion of the bitumen, and in some cases entirely destitute of it."

About three years ago M. Vital, Ingénieur des Mines in France, showed that a flame resembling that produced by a blasting shot which blows out the tamping is greatly lengthened in an atmosphere containing a cloud of coal-dust; and soon afterwards the writer ascertained that air containing a small proportion of fire-damp (less than one per cent. by volume) becomes highly inflammable when coal-dust is mixed with it.

These discoveries complete what Lyell and Faraday began, and show how explosions of any conceivable magnitude may occur in mines containing dry coal-dust. A blasting shot or a small local explosion of firedamp, or a naked light exposed when a cloud of coal-dust is raised up by a fall of roof in air already containing a little firedamp is sufficient to initiate them, and, when once they are begun, they become self-sustaining.

These remarkable facts are either not yet sufficiently well known or their true significance is not yet fully appreciated. In conclusion I may state that out of many hundred collieries known to me there is not, to my knowledge, a single damp one in which a great explosion has happened; while, on the other hand, there is a considerable number of very dry ones in which explosions causing the deaths of from 12 to 178 men at a time have occurred.

W. GALLOWAY

[1] In the reports of the Inspectors of Mines, human bodies, timber, and coal, are described as being *charred* or *burnt* where they are covered with this deposit.—W. G.

THE SUN'S PHOTOSPHERE

DR. JANSSEN has just made a communication to the French Academy of Sciences, which will be received with interest, not only by students of solar physics, but by all who follow the various triumphs achieved by modern scientific methods. It seems a paradox that discoveries can be made depending on the appearance of the sun's surface by observations in which the eye applied to the telescope is powerless; but this is the statement made by Dr. Janssen himself, and there is little doubt that he has proved his point.

Before we come to the discovery itself let us say a little concerning Dr. Janssen's recent endeavours. Among the six large telescopes which now form a part of the equipment of the new physical observatory recently established by the French government at Meudon, in the grounds of the princely Château, there is one to which Dr. Janssen has recently almost exclusively confined his attention. It is a photoheliograph giving images of the sun on an enormous scale—compared with which the pictures obtained by the Kew photoheliograph are, so to speak, pigmies, while the perfection of the image and the photographic processes employed are so exquisite, that the finest mottling on the sun's surface cannot be overlooked by those even who are profoundly ignorant of the interest which attaches to it.

This perfection and size of image have been obtained by Dr. Janssen by combining all that is best in the principles utilised in one direction by Mr. De la Rue, and in the other by Mr. Rutherfurd. In the Kew photoheliograph, which has done such noble work in its day that it will be regarded with the utmost veneration in the future, we have first a small object-glass corrected after the manner of photographic lenses, so as to make the so-called actinic and the visual rays coincide, and then the image formed by this lens is enlarged by a secondary magnifier constructed, though perhaps not too accurately, so as to make the actinic and visual rays unite in a second image on a prepared plate. Mr. Rutherfurd's beautiful photographs of the sun were obtained in a somewhat different manner. In his object-glass he discarded the visual rays altogether and brought only the blue rays to a focus, but when enlargements were made an ordinary photographic lens—that is, one in which the blue and yellow rays are made to coincide—was used.

Dr. Janssen uses a secondary magnifier, but with the assistance of M. Pragmowski he has taken care that both it and the object-glass are effective only for those rays which are most strongly photographic. Nor is this all; he has not feared largely to increase the apertures and focal length, so that the total length of the Kew instrument is less than one-third of that in operation in Paris.

The largely-increased aperture which Dr. Janssen has given to his instrument is a point of great importance. In the early days of solar photography the aperture used was small, in order to prevent over-exposure. It was soon found that this small aperture, as was to be expected, produced poor images in consequence of the diffraction effects brought about by it. It then became a question of increasing the aperture while the exposure was reduced, and many forms of instantaneous shutters have been suggested with this end in view. With these, if a spring be used, the narrow slit[1] which flashes across the beam to pay the light out into the plate changes its velocity during its passage as the tension of the spring changes. Of this again Dr. Janssen has not been unmindful, and he has invented a contrivance in which the velocity is constant during the whole length of run of the shutter.

By these various arrangements the plates have now been produced at Meudon of fifteen inches diameter, showing details on the sun's surface of less than one second of arc.

So much for the *modus operandi*. Now for the branch of solar work which has been advanced.

It is more than fifteen years ago since the question of the minute structure of the solar photosphere was one of the questions of the day. The so-called "mottling" had long been observed. The keen-eyed Dawes had pointed out the thatch-like formation of the penumbra of spots, when one day Mr. Nasmyth announced the discovery that the whole sun was covered with objects resembling willow leaves, most strangely and effectively interlaced. I here quote from Sir John Herschel.[2]

> "According to his observations, made with a very fine telescope of his own making, the bright surface of the sun consists of separate, insulated, individual objects or *things*, all nearly or exactly of one certain definite size and shape, which is more like that of a willow leaf, as he describes them, than anything else. These leaves or scales are not arranged in any order (as those on a butterfly's wing are), but lie crossing one another in all directions, like what are called spills in the game of spilikins; except at the borders of a spot, where they point for the most part inwards, towards the middle of the spot, presenting much the sort of appearance that the small leaves of some water-plants or seaweeds do at the edge of a deep hole of clear water. The exceedingly definite shape of these objects; their exact similarity one to another; and the way in which they lie across and athwart each other (except where they form a sort of bridge across a spot, in which case they seem to affect a common direction, that, namely, of the bridge itself), all these characters seem quite repugnant to the notion of their being of a vaporous, a cloudy, or of a fluid nature. Nothing remains but to consider them as separate and independent sheets, flakes, or scales, having some sort of solidity. And these flakes, be they what they may, and whatever may be said about the dashing of meteoric stones into the sun's atmosphere, &c., are evidently the *immediate sources of the solar light and heat*, by whatever mechanism or whatever processes they may be enabled to develop, and as it were elaborate these elements from the bosom of the non-luminous fluid in which they appear to float. Looked at in this point of view, we cannot refuse to regard them as *organisms* of some peculiar and amazing kind . . . ."

Here, then, was a discovery with a vengeance! and absolute endorsement from the man above all others who had a right to express an opinion. Nevertheless, the organisms have since disappeared, and the work of many careful observers has established that the mottling on the sun's surface is due to dome-like masses, and that the "thatch" of the penumbra is due to these dome-like masses being drawn, either directly or in the manner of a cyclone, towards the centre of the spot. In fact the "pores" in the interval between the domes are so many small spots, while the faculæ are the higher levels of the cloudy surface. The fact that faculæ are so much better seen near the limb proves that the absorption of the solar atmosphere rapidly changes between the levels reached by the upper faculæ and the pores.

These masses are in all probability due to a rapid increase of pressure in the portion of the solar atmosphere occupied by the photosphere; we know, or think we know, that they are not due to reduction of temperature.

Thus much presumed we now come to Dr. Janssen's discovery.

An attentive examination of his photographs shows that the surface of the photosphere has not a constitution uniform in all its parts, *but that it is divided into a series of figures more or less distant from each other, and presenting a peculiar constitution.* These figures have contours more or less rounded, often very rectilinear, and generally resembling polygons. The dimensions of these figures are very variable; they attain sometimes a minute and more in diameter.

While in the interval of the figures of which we speak the grains are clear, distinctly terminated, although of very variable size, in the interior the grains are as if half effaced, stretched, strained; for the most part, indeed, they have disappeared to make way for trains of matter which have replaced the granulation. Everything indicates that in these spaces, as in the penumbræ of spots, the photospheric matter is submitted to violent movements which have confused the granular elements.

In an article recently contributed by Dr. Hunter and myself to the *Nineteenth Century*,[1] the following passage occurs :—

> "The spots may be taken as a rough index of solar energy, just as the rainfall may be taken as a convenient indication of terrestrial climate. *They are an index but not a measure* of solar activity; and their absence indicates a reduction, not the cessation, of the sun's energy. *Whether this reduction means one in a hundred or one in a thousand we do not know.*"

With the same idea in his mind Dr. Janssen points out that this fact throws light upon the forms of solar activity, and shows that that activity, in the photosphere, is always very great, although no spot appears on the surface.

We have already referred to the paradox that the sun's appearance can now be best studied without the eye applied to the telescope. This is what Dr. Janssen says on that point.

The photospheric network cannot be discovered by optical methods applied directly to the sun. In fact, to ascertain it from the proofs, it is necessary to employ glasses which enable us to embrace a certain extent of the photographic image. Then if the magnifying power is quite suitable, if the proof is quite pure, and especially if it has received rigorously the proper exposure, it will be seen that the granulation has not everywhere the same distinctness, that the parts consisting of well-formed grains appear as currents which circulate so as to circumscribe spaces where the phenomena present the aspect we have described. But to establish this fact, it is necessary to embrace a considerable portion of the solar disc, and it is this which it is impossible to realise when we look at the sun in a very powerful instrument the field of which is, by the very fact of its power, very small. In these conditions we may very easily conclude that there exist portions where the granulation ceases to be distinct or even visible ; but it is impossible to suppose that this fact is connected with a general system.

---

[1] I have recently been making some experiments with a view of getting rid of the narrow aperture in general use, as it has appeared to me that the diffraction effects produced by it must be as injurious to definition as those due to a small object-glass. I have found that a circular aperture, allowing the whole beam to be flashed on the plate in conjunction with a plate of optically pure yellow glass nearly in contact with the photographic plate can be used without over-exposure.

[2] "Familiar Lectures," p. 87.

[1] "Sun-spots and Famines," *Nineteenth Century*, November, 1877, p. 584.

We have written enough to show that when the daily history of the sun comes to be recorded another method and another point of view have now been added as the first fruits of Dr. Janssen's labours in his new observatory.

J. NORMAN LOCKYER

FOWNES' "MANUAL OF CHEMISTRY"

Fownes' Manual of Chemistry. Vol. II. Chemistry of Carbon Compounds, or Organic Chemistry. Twelfth Edition. By H. Watts, B.A., F.R.S. (London: Churchill, 1877.)

ORGANIC chemistry is now progressing with such rapid strides, that a work on this subject becomes antiquated, at least in some parts, in the course of a few years. A new edition of a well known and favourite book must therefore be most welcome to students of this branch of chemical science, and more so when edited by a man whom we may justly call "the English Gmelin."

The old familiar, bulky Fownes has now been divided into two handy volumes, enabling the editor to devote the same space to the carbon compounds as to inorganic chemistry.

The arrangement of the subject is in principle almost the same as in the last edition ; organic compounds being divided into hydrocarbons, alcohols, ethers, amido-compounds, organo-metallic bodies, acids, &c., the compounds of each group being arranged in homologous series.

Physiological chemistry is omitted, and this must be considered as an improvement, as that branch of chemical science now requires special treatment in a separate work.

The name of the author is a sufficient guarantee for the soundness of the knowledge which this book imparts, and we hope to see it soon in the hands of numerous students who will find it a most useful and trustworthy guide, embracing as it does the most important recent researches. The book is singularly free from misprints, and the few which we have found can be easily corrected by a student who is accustomed to think for himself.

As a reviewer is expected to point out any faults, we will do so, but "sine iræ et studia," and only for the benefit of the students who will largely use this work.

Thus we miss an account of the normal sulphuric ethers, which are found by the action of sulphuryl chloride, or oxychloride on the alcohols and phenols. Perhaps these parts were written before the researches we allude to were published, and the same may be the case with phenyl-sulphuric acid, and its homologues, compounds which possess such interest both for the chemist and physiologist. To lactide, the author still assigns the old formula $C_3H_4O_2$, although Henry has proved, by determining its vapour density, that its molecular formula is $C_6H_8O_4$. On page 285 we find a statement which might lead a beginner in practical work to disappointment, it is there said that "crude acetyl chloride is purified by heating it with water and dilute soda solution." "Quandoque bonus dormitat Homerus."

We were much pleased to find that Mr. Watts has given particular attention to the study of isomerism, especially among the derivatives of benzene, and he justly says in the preface : "This part of the subject is here presented in a form in which it has not yet appeared in any English publication, except in the *Journal* of the Chemical Society."

Speaking of the disubstitution products of benzene, the following definition is given : "A di-derivative of benzene is para-, ortho-, or meta-, according as it can give rise to, or be formed from, one, two, or three tri-derivatives. This definition is, however, incomplete, and only holds good if in the di derivative the substituting elements or radicals are the same. For it is easily seen that, to take the most simple case, a para-compound containing two different groups such as paranitrobromobenzene can give rise to or be formed from two different amidonitrobromobenzenes. The oversight is, however, a matter of small importance, and an attentive student will not be led astray by it.

The theory of structure or position which Mr. Watts treats so fully has been lately attacked by eminent chemists who seem to overlook or forget the great impulse which this theory has given to the progress of organic chemistry. The "modern chemists," as they sneeringly have been called, know well enough that the structural formulæ which they use do not pretend to give a picture of the real position of atoms in space, and do not mean more than the parallelogram of forces in mechanics, *i.e.*, they only express the manner in which the different forces of the atoms attract each other. They fully understand that their present theory, with the progress of science will have to undergo many modifications, and it is not a dogma, but will stand or fall on its own merits.

The opponents of the modern school remind us of the last followers of the phlogistic theory who got hold of any fact which the antiphlogistonists were not able to explain as a proof that the latter were in the wrong. We can easily imagine how pleased Priestley was when it was found that when heating certain metallic calces with charcoal an inflammable air was formed, whereas, according to Lavoisier's school, only carbonic acid could be produced. Just in the same way the opponents of the structural theory point out that the existence of four lactic acids is incompatible with it ; and Mr. Watts himself, although a strong adherent of the theory of structure, shirks the discussion of this point, and rusticates one of the four in a foot-note, in which he expresses his doubts as to its existence.

The recent researches of Wislicenus, however, hardly leave any doubt that four such acids exist. We must confess that we are not able to explain the difference between hydracrylic acid and ethenelactic acid, and quite agree with Mr. Watts that Wislicenus' explanation of the cause of their isomerism is improvable and far-fetched. But there exist other isomeric compounds which, like these two acids, have apparently the same chemical constitution, and in some of these cases it has lately been shown that the bodies are not chemical isomerides but physical isomorphides, or differ from each other in exactly the same way as calcite differs from arragonite. We have not the least doubt that the cause of the isomerism of the lactic acids will, at no distant time, also find a satisfactory explanation, because we are convinced that organic chemistry is working in the right direction. Time will show whether we prophesy truly or not.

OUR BOOK SHELF

Transcaucasia and Ararat; being Notes of a Vacation Tour in the Autumn of 1876. By James Bryce. (London: Macmillan and Co., 1877.)

ALTHOUGH in this narrative Prof. Bryce takes the reader over pretty well-known ground, about parts of which, at least, much has been written, still even the best-informed readers will read his book with pleasure and profit. Prof. Bryce used his own eyes, and as he is a good and independent observer, there is an unusual freshness about his narrative. He journeyed down the Volga, crossed the southern steppe and the Caucasus to Ararat, which he ascended, thence to the shore of the Black Sea, sailing along the coast to Constantinople. Nijni Novgorod Fair, he thinks, has been much over-estimated in some respects, and he has a good word to say of the recently much-abused Cossack. Prof. Bryce is a good geologist, and his work abounds with interesting notes on the geology as well as the flora of the regions which he traversed. Perhaps the most interesting chapter in his book is that in which he describes his ascent of Mount Ararat. In a previous chapter he has collected much valuable information concerning the mountain, the legends connected with it, its geology, volcanic phenomena, meteorology, vegetation, and animals. Prof. Bryce, with a companion, six Cossack soldiers, and an interpreter, set out from Aralyk, a little to the north of the mountain, at 8 A.M., on September 11 last year, to attempt the ascent. About noon they were fairly on the side of Ararat, and at about 6,000 feet came upon a small Kurd encampment, some of the Kurds, with their oxen, being induced to act as baggage-bearers. At the well of Sardar-bulakh they camped late in the afternoon, about 7,500 feet above the sea. About one A.M. they started again, thirteen in all, but as they proceeded, with many vexatious halts, the Cossacks dropped off one by one, and at last, at about 12,000 feet, Prof. Bryce resolved to take what he wanted in the way of food, and start at his own pace. Two Cossacks and a Kurd accompanied him to the height of about 13,600 feet, when they too dropped off, and Prof. Bryce resolved to accomplish the remainder of the 17,000 feet alone, a hazardous undertaking even for a trained Alpinist. Partly up a rocky slope which seems to extend considerably beyond the snow-line, and partly over the soft snow itself, and enveloped much of the time in cloud, Prof. Bryce continued his solitary and fatiguing climb, until about half-past two P.M., he became convinced that he was really on the top of Ararat, at least one of the tops, for there are two, one about thirty feet higher than the other, and he did not descend until he had set his feet on both. There were difficulties and dangers both in the ascent and descent, though they do not seem to be nearly so great, judging from Prof. Bryce's description, as those which attend the ascent of a moderate Alpine summit. Prof. Bryce reached his companions again in safety. Notwithstanding he had to make all haste to reach the summit, he had time to make several interesting notes of what he saw by the way, the evidences of volcanic action particularly attracting his attention. To show the superstitious awe with which the sacred summit is regarded in the region around, Prof. Bryce tells that when the Archimandrite of Etchmiadzin was told that the English-man had ascended to the top of "Massis," the venerable man replied, smiling sweetly, "No, that cannot be. No one has ever been there. It is impossible." Prof. Bryce's is the sixth known ascent of Ararat, the first having been made in 1829 by Dr. Frederick Parrot, a Russo-German professor in Dorpat University.

Thermodynamics. By R. Wormell. (The London Science Class-books. Elementary Series. Longmans, 1877.)

THIS work is one of the earliest published of a series "adapted for school purposes," and "composed with special reference to use in school teaching," as we are told in the general preface.

We feel very strongly that no good can come of the introduction of such subjects as the dynamical theory of heat into school-teaching. That an average school-boy can be taught the elements of such subjects as astronomy, botany, and natural history, and that he will to a certain extent profit by such teaching, may probably be true; but only in so far as his powers of observation are concerned. We believe that it is a complete mistake in practical education to try to carry the process farther than the elements, even in the case of the comparatively easy subjects just named.

Some elementary experimental facts connected with heat might, no doubt, be added to the list. But it is simply the work of the crammer to stuff a school-boy's head with such utterly unassimilable materials as reversible engines, absolute temperature, and the kinetic theory of gases. This is education run mad.

This obvious consideration decides at once our opinion as to the value of the work before us. It is beyond the intelligence of schoolboys, and in the hopeless endeavour to sink it to *their* level it has been deprived of much that might have made it a serviceable work for more mature minds.

After what we have said, it would be superfluous to criticise the book minutely, for nearly all our objections would be mere repetitions in part of the first and general one. We note, however, a want of strictness, or at least of completeness, in some of the mathematical proofs. The first example we meet with may serve as a type. Thus (p. 4) it is assumed, without any attempt at explanation, in fact without a word to warn the reader that a distinct step has been taken, that in uniformly accelerated motion the mean velocity during any period is half the sum of the initial and final velocities--a truth, and a very important one, but most certainly not self-evident to the average schoolboy.

Simple Lessons for Home Use. (London: E. Stanford, 1877.)

THESE simple lessons are intended for younger children than those for whom the primers published by Messrs. Macmillan have been written, and they appear admirably adapted for the purpose they have in view. Mr. W. E. Forster, in his recent speech at Huddersfield, referred to the importance of teaching the elements of science in primary schools by means of appropriate reading books. The little books before us, so far as they go, meet the wish expressed by Mr. Forster. The print is clear, the language on the whole simple, and the price (threepence) places them within the reach of the humblest. Perhaps there is a little too great a tendency to moralise in parts of the otherwise capital little lessons on birds and money. The author of the last-named—the Rev. T. E. Crallan—tells in a simple and interesting way how money grows, and writes for younger minds than does the Rev. G. Henslow, who contributes lessons on flowers, where too many technical terms are, we think, introduced, especially in the first chapter. Miss Fenwick Miller's lessons on the human body, and on ventilation, are excellent, and so are Mr. Philip Bevan's on food, and Dr. Mann's on the weather. Altogether, we congratulate the publisher on the subjects selected, and the authors he has chosen: no doubt the remainder of the lessons that are to be issued will confirm the high opinion we have formed of those already before us. W. F. B.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.]

Appunn and Koenig.—Beats in Confined Air

IN my letter published in NATURE (vol. xvi. p. 227), I stated that I should re-examine the question of the discrepancy between Appunn and Koenig, and inform you of the result. During the whole month of September I was engaged in very carefully counting and recounting Appunn's tonometer in the South Kensington Museum, the reeds of which had got a little out of order, a circumstance which did not interfere with the ascertainment of pitch, but disposed at once of any errors in Appunn's pendulum. I employed one of Webster's ship chronometers, which was rated to lose one second daily, and counted each set of beats repeatedly through one or two minutes. I ascertained by this means that the objections made by Koenig on the score of false pendulums and false counting were entirely groundless, and that the former determinations of the relative pitch of Koenig's forks and Appunn's reeds, made by Dr. Preyer and myself, were practically correct.

But as Lord Rayleigh pointed out in NATURE (vol. xvii. p. 12) the practical agreement of the results obtained by Professors Mayer and MacLeod, and by his own new method there described, with Koenig's, serves to show that there is a physical phenomenon to be accounted for. Mr. Bosanquet had drawn my attention to the subject several months ago, and my own experiments on the beating of disturbed consonances had led me to the same conclusion. Accordingly I had devised a series of experiments for ascertaining the fact, the nature of which I lately communicated to Lord Rayleigh; but as they required the use of two tonometers excited by separate bellows, there were difficulties in the way of making them, which I did not overcome till this week. To-day I made the first of these experiments, lasting four hours or more, and ascertained—

1. That the beats of the harmonium reeds in Appunn's tonometer *are* affected by taking place in a confined space of air.
2. That they are *accelerated*, and
3. That the acceleration, being roughly about one per cent., will probably, when completely ascertained, account for the discrepancy observed.

Details have been sent privately to Lord Rayleigh; they are too incomplete for publication. The experiments will require many weeks to complete with the necessary accuracy. But in the meantime I hasten to communicate an important acoustical fact which may bear upon many other phenomena besides the ascertainment of absolute pitch. ALEXANDER J. ELLIS

25, Argyll Road, Kensington, November 3

The Radiometer and its Lessons

As I now learn for the first time what are the grounds on which Prof G. C. Foster based his inculpation of me, I may ask for a *very* few last words. I fully admit that in giving a sketch of the history of the Radiometer, I *intended* to attribute to Mr. Crookes that he had in the first instance put a wrong interpretation upon his own results; because I believed that this was a simple fact, well known to everybody who had followed the history of the inquiry. And Prof. Carey Foster has not called in question the correctness of my statement of the general impression which prevailed among scientific men, alike when Mr. Crookes first exhibited his radiometer at the *soirée* of the Royal Society, and when its phenomena were discussed at the subsequent meeting. Having followed that discussion with the greatest interest, I cannot now recall one word that was not in harmony with the "direct impact" doctrine, or that suggested the idea of "heat reaction" through residual gas. If the question had been then asked, whether the rotation would continue to take place in an *open* vacuum (were such possible), or in a *perfect* vacuum,—so as to eliminate all "reaction," through residual gas, between the vanes and the containing flask,—I believe that the general, if not the unanimous, verdict would have been in the affirmative. Certainly I heard nothing from Mr. Crookes on the other side, he having previously spoken of the dependence of the "Repulsion resulting from Radiation on the presence of residual gas as 'impossible to conceive.'"

It is clear, then, that in referring to this then prevalent view, I no more wished to put Mr. Crookes in the wrong, than I wished to put in the wrong my very excellent friends among the other eminent Physicists who shared it; the special purpose of this part of my paper being to bring out, as strongly as I could, *the thoroughly scientific and philosophical method in which Mr. Crookes afterwards worked himself right.* If this is not expressed in as much detail as Prof. G. C. Foster would have approved, it surely afforded no adequate ground for his going out of his way to charge me with having "depreciated Mr. Crookes's merits." Yet this is the *only* ground that I can find in the whole of Prof. Carey Foster's statement, for what I could not but regard as a very grave imputation.

On Mr. Crookes's reply I shall make but a single remark, with reference to his perfectly correct citation of the latter part of my conversation with him, on the occasion of his receiving the Royal Medal. If I had not found, after the publication of my Lectures (in which I said nothing but what was respectful to Mr. Crookes), that he had himself been "digging up the hatchet" which I was quite disposed to keep buried, by giving his public attestation to the "spiritualistic" genuineness of what had been proved to be a most barefaced imposture, I should not have again brought his name into the controversy. But I felt that his greatly increased reputation as a Scientific man would do an increasing injury to what I honestly believed to be the cause of reason and common sense, not only in this country but still more in the United States.

Since the death of Prof. Hare, not a single scientific man of note (so far as I am aware) has there joined the Spiritualistic ranks; but the names of the "eminent British scientists," Messrs. Crookes and Wallace, are a "tower of strength" to the various orders of "mediums"—rapping mediums, writing mediums, drawing mediums, materialising mediums, test mediums, photographic mediums, trance mediums, healing mediums, and the like—*whose names form many columns* of the "Boston Trades' Directory." And the now notorious impostor, Eva Fay, has been able to appeal to the "endorsement" given to her by the "scientific tests" applied to her by "Prof. Crookes and other Fellows of the Royal Society," which had been published (I now find) by Mr. Crookes himself in the *Spiritualist* in March, 1875. Within two months of that date, as Mr. Maskelyne has publicly stated, an offer was made him (I have myself seen copies of the letters) by Eva Fay's manager, that for an adequate sum of money the "medium" should expose the whole affair, scientific tests and all, "*complicating at least six big guns, the F.R.S. people*," as she was not properly supported by the Spiritualists.

I have therefore felt it incumbent on me to show that in dealing with this subject Messrs. Crookes and Wallace have followed methods which are thoroughly *un*-scientific; and have been led by their "prepossession" to accept with implicit faith a number of statements which ought to be rejected as completely untrustworthy.

My call to take such a part—which I would most gladly lay aside for the scientific investigations which afford me the purest and most undisturbed enjoyment—seems to me the same as is made upon every member of the Profession to which I have the honour to belong, that he should do his utmost to cure or to mitigate *bodily* disease. The training I originally received, and the theoretical and experimental studies of forty years, have given me what I honestly believe (whether rightly or wrongly) to be a rather unusual power of dealing with this subject. Since the appearance of my Lectures I have received a large number of public assurances that they are doing good service in preventing the spread of a noxious *mental* epidemic in this country; and I have been privately informed of several instances, in which persons who had been "bitten" by this malady, have owed their recovery to my treatment. Looking to the danger which threatens us from the United States, of an importation of a real spiritualistic *mania*, far more injurious to our *mental* welfare, than that of the Colorado beetle will be to our *material* interests, I should be untrue to my own convictions of duty if I did not do what in me lies to prevent it. That I do not take an exaggerated view of the danger, will be obvious to any reader of Mr. Home's book. I know too well that I thus expose myself to severe obloquy, which (as I am not peculiarly thick-skinned) will be very unpleasant to myself, and unfortunately still more so to some who are nearly connected with me. But I am content to brave all, if I can believe that my *exposé* will be of the least service either to individuals or to society at large. W. B. CARPENTER

THE high scientific position which Prof. Foster holds, as well as the decided manner in which his letter was written, must lead the otherwise unbiassed reader to the conclusion that not only has a satisfactory explanation of the action in question been found and generally adopted, but that this explanation turns upon certain considerations, and particularly on the mean length of the path of the gaseous molecules as influenced by the degree of rarefaction.

I feel my position, therefore, particularly unfortunate in having, for the sake of truth, to show that the explanation which Prof. Foster has adopted, and supposes others to have adopted, is, if judged by the statements in his letter, inconsistent with well-established laws.

Prof. Foster gives me credit for having originated the fundamental idea of the explanation, but states that my "explanation was theoretically incomplete; in particular it did not show clearly why so high a degree of rarefaction should be necessary for the production of the phenomenon in question;" and then he proceeds to explain how this asserted deficiency was supplied by other thinkers, who showed that "the increase, resulting from rarefaction, in the mean length of the path of the gaseous molecules, would favour the action."

It is this supposed completion of my explanation that is erroneous. It is contrary to the law of the diffusion of heat in gases that "the increase, resulting from rarefaction, in the mean length of the path of the gaseous molecules would favour the action," and so far from supplying any deficiency in my explanation it is incompatible with it. The only result from such an increase is to diminish the action—a result which rises into importance only when the rarefaction is carried so far that the mean length of the path of a molecule becomes comparable with the dimensions of the inclosing vessel.

In my first paper I gave a definite proof, which has nowhere been questioned, that according to the kinetic theory the force arising from the communication of heat from a surface to adjacent gas of any particular kind depends only on one thing, the rate at which heat is communicated, and to this it is proportional. If therefore the increased rarefaction increased the force it must increase the rate at which heat is communicated, but according to the law established by Prof. Maxwell the rate at which heat is communicated is independent of the density of the gas, whence it follows that the increase in the mean length of the path of the gaseous molecules, resulting from rarefaction, cannot favour the action which remains approximately constant until the gas becomes so rare that the law of diffusion no longer holds, after which it may easily be shown the communication of heat, and hence the action in question, diminishes but never increases.

The fact that in the radiometer the force caused by the communication of heat only causes motion when the surrounding gas becomes extremely rare is, as I pointed out in my first papers, fully explained by the action of what I have called convection currents, which action depends on the weight and density of the gas. The gas adjacent to the hot surface is hotter than that which is more remote, and hence the former rises forming an ascending column, to supply which the gas is drawn in laterally on all sides, and tends to carry the surface forward with it. With the same difference of temperature and surrounding circumstances the speed of these convection currents is the same whatever may be the density of the gas, and hence the force which they exert on the surface is proportional to the density of the gas.

This force is opposite in direction to that arising from the communication of heat to the gas, and since the former diminishes with the density while the latter is constant, there must be some density for which they balance, and below which the constant force will predominate, while above this point the convection currents will carry the surface with them. The fact that, starting from low densities, the motion of the vanes in the radiometer does not only diminish as the density increases, but is actually reversed at higher densities, requires explanation, and no other than this has yet been offered.

I have gone into the subject at considerable length, as I felt bound, when venturing to differ from so high an authority as Prof. Foster, to state my reasons. There is, however, nothing in what I have said here which I have not said elsewhere, in the same or other words; and however incomplete in theory the explanation given in my first papers may be, I can only say that it included all the facts known to me at the time these were written; it has led me to predict many of the experimental results which have since been obtained, and I have not been able to find one fact with which it is not in accordance, nor has it been, so far as I am aware, controverted in any particular.

OSBORNE REYNOLDS

Potential Energy

I HAVE reason to believe that the "grievous error" with which I charged "John O'Toole" in his reference to the clock is not meant by him to be his own view of the matter at all, but merely a legitimate deduction from the confused and inconsistent language of "the doctors." Such an erroneous view on his part is, indeed, obviously out of harmony with the extensive knowledge of the subject of energy displayed by him in letters which, without doubt, will convince "the doctors" of the necessity of adopting consistent and strictly logical phraseology.

Effects of Urticating Organs of Millepora on the Tongue

AN article by Mr. Moseley, in NATURE (vol. xvi. p. 475), reminds me of an experiment I made some years ago in Florida. In collecting corals on the reefs, I had of course become familiar with the disagreeable, though not very painful, effects of contact of the hands with Millepora. But the vulgar names of Pepper-coral or Sea ginger induced me to try the effect on the tongue, to find out how far the taste resembled those condiments. I accordingly broke off a fresh piece and applied it to the tongue. Instantly a most severe pain shot, not only through that organ, but also through the jaws and teeth. The whole course of the dental nerves and their ramifications into every single tooth could be distinctly and painfully felt. I can compare the sensation to nothing better than to the application of the poles of a pretty strong galvanic battery. The pain remained severe for about half an hour, then became duller, leaving a sensation still perceptible five or six hours later. The whole impression was much too violent to allow the distinction of any particular taste.

Such an experiment made with Physalia might be positively dangerous, considering the much more powerful urticating effects of its polyps. Indeed, a friend of mine once related to me that when a boy he had come in contact with one of the long tentacles of a Physalia, when bathing, and had to be carried out of the water almost fainting. L. F. POURTALES

Cambridge, Mass., October 22

Drowned by a Devil Fish

THE following account of the destruction of a human being by a cuttle fish at Victoria, in Vancouver Island, has all the appearance of authenticity about it. It occurs in the *Weekly Oregonian* of October 6, 1877. The *Oregonian* is the principal paper of Oregon, and is published at Portland.

The insertion of the account in NATURE may lead to further information on the subject. I know of no other authentic instance of the kind.

An account of the habits of the huge octopus of the Vancouver Island Sounds and also of the Indian method of hunting and killing the beasts for food is to be found in John Keast Lord's "Naturalist in Vancouver Island and British Columbia," vol. i. p. 192. Mr. Lord measured specimens which had arms five feet in length, with a thickness at their base as great as his wrist, and he once collected a detached sucker of one of these cephalopods as large as an egg cup in mistake for a huge actinia.

"BRITISH COLUMBIA

"*Drowned by a Devil Fish*

"VICTORIA, September 27.—An Indian woman while bathing was pulled beneath the surface of the water by an octopus or devil fish and drowned. The body was discovered the following day in the bottom of the bay in the embrace of the monster. Indians dived down and with their knives severed the tentacles of the octopus and rescued the body. This is the first recorded instance of death from such a cause in this locality, but there have been several narrow escapes."

Exeter College, Oxford H. N. MOSELEY

The Earthworm in Relation to the Fertility of the Soil

IN NATURE, vol. xvii., p. 18, there is an account under the above heading of M. Hensen's investigations of this subject, to which I wish to add a note. He says the assertion that the earth-worms gnaw roots is not proved by any fact; roots gnawed by worms were never met with by him, and the contents of the intestines of the worms never included fresh pieces of plants. The experience of gardeners that the earth-worm injures pot plants may be based on the uncovering or mechanical tearing of the roots.

I should have thought that the universal experience of gardeners is that earth-worms never eat vegetable matter until it has decayed, and that their instinct leads them to draw the points of leaves as far as they can into their tubes for the purpose of setting up the decaying process, and likewise to sever the roots of pot plants with the same object. I can hardly understand how earth-worms have any mechanical means of severing the roots of plants except by gnawing.

But there is an omission in M. Hensen's account of the fertilisation of the subsoil by earth-worms which surprises me. He mentions but two ways in which this is effected, viz., by the opening of passages for the roots into deeper parts, and by the lining of these passages with humus.

I thought it was a well-known fact that worms, by means of their "casts," effect a complete *renversement* of the soil of meadow land down to a certain depth in the course of a few years. But whether well-known or not I met with a demonstration of this important fact in 1857. When putting down a considerable extent of iron fencing in the alluvial meadows near my house (consequent upon an exchange of land) I had occasion to cut a ditch two or three feet deep, and when the workmen had finished the ditch—a quarter of a mile long in all—I was astonished to see in one portion, of about sixty yards in length, a distinct and very even narrow line of coal-ashes mixed with small coal in the clean cut surface of the fine loam of the ditch face, perfectly parallel with the top sward. It immediately occurred to me that this was the work of the earth-worms, and upon inquiry I found that the farmer, who had occupied this land for many years, remembered having once, and only once, carted out some coal-ashes and spread it at this spot not many years before. I forget the exact number of years, but I believe it was about eighteen. I have a distinct recollection, however, that the depth of the line of coal-ashes below the surface was at least seven inches, and that this seemed to confirm the general belief that the depth to which the earth-worm usually burrows is about that amount. I may add that the colour of the loam above the line of coal-ashes was decidedly darker than of that below.

HENRY COOPER KEY

Stretton Rectory, Hereford, November 2

IN NATURE, vol. xvii. p. 18, some details are given of observations made by M. Hensen on the relation of the earthworm to the fertility of the ground. He has observed, as everyone must have observed, that the earthworm during night draws into its tube or hole the loose leaves and fibres which may be lying about. But this operation of the earthworm has a significance in relation to the vegetable world of even a profounder kind than that of the fertilisation of the soil. Some months ago, in searching for young ash plants with three cotyledons, I found that in a great many cases the samara or seed of the ash had been drawn into a worm's hole, and had there found moisture and other essential conditions of growth; while the same seeds lying dry upon the surface had not germinated. There can thus be no doubt that many seeds of all kinds are drawn under the surface of the ground, or covered by the earth thrown up by worms. They are thus preserved from birds and various enemies, and are placed in the proper position for germination. The dead plant is perpetuated from its fallen panicle by the earthworm. An ash tree, or a whole forest of ash trees, may have been planted by earthworms.

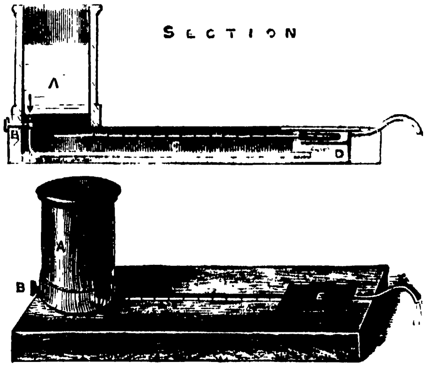
North Kinmundy, November 5 A. STEPHEN WILSON

M. Alluard's Condensing Hygrometer

THE notice of the above instrument in last week's NATURE (p. 14) is an excellent illustration of the necessity for increased communication between the scientific men of all countries. The labour which is at present wasted by repeating what has been done before is enormous, and until international intercommunication is improved it must be so.

I quite agree with you in your appreciation of M. Alluard's hygrometer, but I think it is desirable to state that it is not the first in which "the part on which the deposit of dew is to be observed is a plane well-polished face A, of silver or gilt brass." The annexed engravings represent the form of plane-faced hygrometer invented by Mr. G. Dines, F.M.S., described by him in the *Meteorological Magazine* for October, 1871, and exhibited at the Brighton Meeting of the British Association, 1872.

The action is extremely simple; no ether is required nor any aspirator. Water colder than the dew point is the only requisite—it is poured into the reservoir A, passes through the regulating-tap B into the chamber D; it is, by the black diaphragm, thrown past the bulb of the thermometer C, and then allowed to escape. The cooled plane surface E of silver or black glass, is excessively thin, and the space between it and the thermometer-bulb is wholly occupied by the effluent water, so that the great essential of all hygrometers, a true indication of the temperature of the cooled surface, seems to be reached. The plate E can be kept within 0°·2 or 0°·3 for a length of time by adjusting the screw B, and as the condensation usually takes an elliptical form over the thermometer-bulb, and in the middle of F, the advantage of an adjacent bright surface is usually attained. I am, however, not sure that M. Alluard's surrounding plate might not be a convenience, although for the reason above given I have not found it necessary.



G. J. SYMONS

62, Camden Square, N.W., November 2

Optical Spectroscopy of the Red End of the Solar Spectrum

NATURE, dated August 2 (vol. xvi. p. 264), containing Profᶠ. Piazzi Smyth's communication on "Optical Spectroscopy of the Red End of the Solar Spectrum," reached me on the 21st ult., when I had no leisure to avail myself of the outgoing mail and reply immediately to the subject of his last paragraph. Inquiry is there made of "anyone" (besides the Royal Society), in association more or less with my name, whether *more recent particulars* have been published, of the spectrum in question, than "those (*i.e.* my) Indian observations," "printed in the *Philosophical Transactions* so long ago as 1874" (*i.e.* 1875).

2. The Astronomer-Royal for Scotland is presumably in a better position to reply for "any one," than myself, located in latitude N. 30°, longitude E. 78°; and so far as the inquiry re[illegible]es to the Royal Society, his penultimate paragraph in itself furnishes the information sought, because the Society's publica-

tion prominently alluded to by himself *is the last* publication. As respects myself, I have printed no further particulars in addition to those which the Professor dismisses, briefly for the present, with the announcement of having discovered, "total contradictions" to certain "conspicuous features."

3. It is necessary to point out, that the designation for my observations adopted by the Professor of "the Royal Society's and Mr. Hennessey's high-sun series" suggests existence of the *divided* responsibility which is plainly disavowed in the "Advertisement" to the *Philosophical Transactions*, 1875, Part I., and elsewhere; for the professor can hardly intend that two separate and independent high-sun series taken on the Himalaya Mountains, one by the Royal Society, and the other by myself, have appeared in the *Transactions*.

4. I shall look forward with interest to the perusal of Prof. Piazzi Smyth's promised *complete* account of his sun-high observations at Lisbon; meanwhile I may be pardoned for my inability to follow his prompt and brief announcement of "total contradictions," written while yet on his return voyage.

J. B. N. HENNESSEY

N.W. Provinces, India, Dehra Doon, October 3

Singing Mice

PERHAPS the following account of a singing mouse may be of interest to your readers:—

Last winter we occupied the rooms we now do at Menton. Early in February we heard as we thought the song of a canary, and fancied it was outside our balcony; however we soon discovered that the singing was in our *salon*, and that the songster was a mouse; at that time the weather was rather cold, and we had a little fire, and the mouse spent most of the day under the fender, where we kept it supplied with bits of biscuit; in a few days it became quite tame, and would come on the hearth in an evening and sing for several hours, sometimes it would climb up the chiffonier and ascend a vase of flowers to drink at the water, and then sit and sing on the edge of the table and allow us to go quite near to it without ceasing its warble; one of its favourite haunts was the wood basket, and it would often sit and sing on the edge of it. On February 12, the last night of the carnival, we had a number of friends in our *salon*, and the little mouse sang most vigorously much to their delight and astonishment and was not in the least disturbed by the talking. In the evening the mouse would often run about the room and under the door into the corridor and adjoining rooms, and then return to its own hearth; after amusing us for nearly a month it disappeared, and we suspect it was caught in a trap set in one of the rooms beyond. The mouse was small and had very large ears, which it moved about much whilst singing; the song was not unlike that of the canary in many of its trills, and it sang quite as beautifully as any canary, but it had more variety, and some of its notes were much lower, more like those of the bullfinch. One great peculiarity was a sort of double song, which we had now and then—an air with an accompaniment; the air was loud and full, the notes being low and the accompaniment quite subdued. Some of our party were sure that there was more than one mouse until we had the performance from the edge of the wood basket, and were within a yard or two of it. My son has suggested that many or all mice may have the same power, but that the notes are usually so much higher in the scale that, like the cry of the dormouse and the bat, they are at the verge of the pitch to which the human ear is sensitive; this may be so, but the notes of our mouse were so low and even the highest so far within the limits of the human ear, that I am inclined to think the gift of singing in mice is but of very rare occurrence.

JOSEPH SIDEBOTHAM

Hotel de Menton, Menton, S. France, October 31

SEVERAL years ago I received some of these animals from a friend, and kept them in confinement for one or two months. The description which your correspondent gives of their performance leaves very little to be added by me, as in all respects this description agrees perfectly with my own observations. I write, however, to remark one curious fact about the singing of these mice, namely, that it seemed to be evoked by two very opposite sets of conditions. When undisturbed, the little animals used for the most part to remain quiet during the day, and begin to sing at night; but if at any time they were alarmed, by handling them or otherwise, whether during the day or night, they were sure to sing vigorously. Thus the action seemed to be occasioned either by contentment or by fear. The character of the song, however, was slightly different in the two cases.

That these mice did not learn this art from singing birds there can be no doubt, for they were captured in a house where no such birds were kept. It may be worth while to add that this house (a London one) seemed to have been suddenly invaded, so to speak, by a number of these animals, for although my friend has lived in this house since the year 1862, it was only during a few months that singing mice were heard in it, and during these few months they were heard in considerable numbers.

Regent's Park, November 1 GEORGE J. ROMANES

Meteor

THE following account of a meteor seen here may perhaps interest some of your readers:—

On October 29, at 8h. 1m. 30s. Greenwich mean time, a brilliant meteor exploded in right ascension 268°, declination + 60° (equator of 1855); it left a bright crooked train scarcely half a degree long, which remained visible for about ten seconds, and pointed towards ξ Draconis. The course of the meteor must have been directed downwards, almost exactly towards this observatory. The flash of the explosion was seen by the assistant-astronomer, Mr. Lohse, although he was sitting in such a position as to be unable to see the meteor directly.

Dunecht, Aberdeen, November 3

INTERNATIONAL POLAR EXPEDITIONS

IN February, 1875, when the Arctic Expedition was being prepared, I asked the First Lord of the Admiralty, in Parliament, whether, in view of the small value for scientific purposes of isolated observations in the Arctic regions, in comparison with simultaneous observations at different places, and in view, also, of the interest now taken in Arctic science by foreign Governments, he would postpone for one season the departure of the proposed Arctic Expedition, and in the interval communicate with foreign Governments with a view to the organisation of other expeditions to make observations simultaneously with our own at fixed times? The First Lord said that he considered the preparations for an expedition too far advanced to admit of this, and added: "I should regard the project of combination with other powers to attain the objects in view as one beset with difficulties"—in which, I think, he was in error. In the following month, when the Supplementary Estimate for the Arctic Vote was under discussion, I again drew the attention of the Government and Parliament to the advantages of simultaneous Arctic expeditions (see *Hansard*, vol. ccxxii. p. 1354), and in *Naval Science* for April of the same year, in an article on "Foreign Polar Expeditions," I drew still further attention to the matter, concluding with an extract from a paper by Capt. Weyprecht (who so greatly distinguished himself in the Austro-Hungarian polar expeditions of 1871 and 1872-74), in which he pointed out in the clearest manner the desirability of extending future Arctic researches far beyond mere geographical exploration, and pressing forward with our studies of magnetism, electricity, the best of meteorology, &c. "The solution of these questions cannot," he said, "be expected until all nations which claim to come up to the present high standard of civilisation unite to go hand in hand, setting aside all national rivalries. To bring about decisive scientific results it will be necessary to make a number of simultaneous observations, so conducted that they will furnish a yearly *résumé* of observations made in different parts of the Arctic regions with exactly similar instruments, and from exactly similar instructions."

Upwards of a year ago NATURE gave details of Weyprecht's project for the scientific exploration of the Polar regions. It was referred to on several occasions, and pointed out that Weyprecht's plan was the only satisfactory method of obtaining results of real and permanent value.

The programme has now been extended and completed, and was prepared for submission to the International Meteorological Congress which was to have met at Rome in September, but which has been adjourned to next year. I have just received from my friend Weyprecht a copy, and may summarise its contents as follows :—

The enterprise proposed by Count Wilczek and Capt. Weyprecht has for its aim strictly scientific exploration, purely geographical discovery being a secondary matter. It will be the first step towards a systematic scientific investigation of the regions around the poles of the earth and the minute observation of phenomena peculiar to these regions—phenomena the earnest investigation of which is of the highest importance in connection with a great number of problems with regard to the physics of the globe. The international expedition will have for its aim to make in the Arctic and Antarctic regions, or in the neighbourhood of these regions, and at as many stations as it is possible to establish, synchronous observations according to a programme mutually agreed upon ; for the purpose, on the one hand, of deducing by comparison from observations collected at different points, independently of the peculiarities which characterise the years of different observations, the general laws of the phenomena investigated ; and, on the other hand, of arriving by probable inductions at a knowledge of the chances of penetrating further into the interior of the unknown regions. For this purpose each of the states participating in the work will undertake to equip at its own expense, and send out an expedition to one of the points designated. Each state will of course be at liberty to authorise its expedition to carry on work outside of that mutually agreed on.

The investigations to be made in common bear only on meteorological phenomena, those of terrestrial magnetism, aurora borealis, and on ice phenomena. At each station the observations must be continued one year, from September 1 to August 31. The meteorological observations will be made in conformity with the resolutions of the permanent International Committee, and will relate to atmospheric pressure, the temperature and humidity of the air, the direction and force of the wind, the state of the sky and its degree of clearness, and also to phenomena of condensation. The programme then gives detailed instructions as to methods and instruments of observation, all being arranged to secure accuracy, fulness, and uniformity.

It is probable that each station will be near a coast, and one of the chief objects of the expedition will be to observe the connection between the movements of the ice and the winds and currents, and if these are observed regularly, important results will no doubt be obtained as to the movements of the ice in the Arctic regions, and therefore as to the routes most favourable for reaching the pole. The best ice-observations will of course be at those stations where local conditions have the least influence.

The magnetic observations are divided into absolute determinations and determinations of the three elements. Minute directions are given in the programme as to the method to be followed in taking these observations, the fixing of the positions of the various instruments, the kinds of instruments to be used, the methods of verification and testing, the construction of observatories, &c. These directions, if faithfully carried out, would give the observer plenty of work to do, but the result would be of unprecedented value. In consequence of the persistent perturbations which prevail in these regions, isolated readings made only from hour to hour, even when carried on for long periods, are not sufficient to give with precision the hourly, daily, and monthly magnetic character of the place of observation. It is necessary, consequently, to multiply these observations. Ten observations per hour for each of the three elements will be sufficient, and to insure a rigorous synchronism it is stipulated that the three instruments of variation be read during ten minutes, from minute to minute, viz., at the full minute (– h. 56m. 0s.) the declination, ten seconds after (– h. 56m. 10s) the horizontal intensity, and ten seconds after that (– h. 56m. 20s.) the inclination. Before and after each observation, viz., – h. 52m. 0s., and at – h. 69m. 0s. the form and position of the auroræ should be noted. Immediately after the meteorological observations should be proceeded with in the following order :—Temperature, humidity, winds, clouds, atmospheric pressure. (For magnetic observations it is proposed to use Göttingen mean time.) Besides observations of the regular magnetic variations, it will be of great importance to have made, by three observers, rigidly synchronous readings of the three elements in order to obtain precise data of the total intensity. For this purpose there will be made, during one hour each day, by these observers, from minute to minute, from – h – m. 0s., readings of the three instruments. The hours of these observations should be advanced an hour each day, so as to return to the point of departure at the end of every twenty-four days.

The auroræ should be observed as to their form, their intensity, and their position. The programme then names and describes the various forms assumed by auroræ—arches, streamers, beams, corona borealis, haze, waves, flashes—for the adequate and scientific observation of which the programme gives directions.

The most favourable time for this joint expedition will be October and November, when the temperature is not so low as to necessitate special preparations.

As the absolute simultaneity of the observations is of the utmost importance, each station must be furnished with the means of obtaining the exact longitude; good chronometers will also be necessary. To carry out the above observations to their fullest extent, four observers will suffice for each station, if among the subordinates there are men who can perform the purely mechanical duty of reading the instruments.

The programme concludes with three propositions, the purpose of which is to insure the possibility of the exact comparison of the magnetic observations.

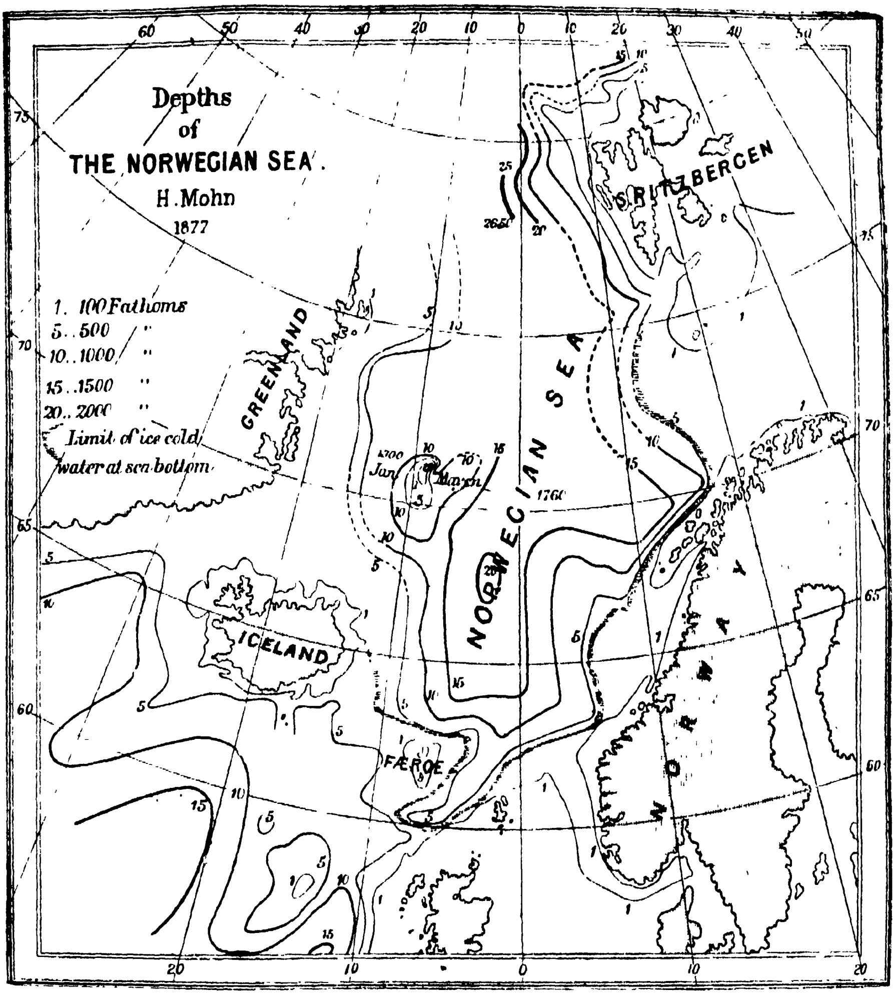
The following are the points proposed as most favourable for the various observations referred to above :—In the northern hemisphere—The north coast of Spitzbergen ; north coast of Novaya Zemlya ; Finmark, near the North Cape ; the mouth of the Lena, on the north coast of Siberia ; New Siberia ; Point Barrow, on the north-east of Behring Strait ; the west coast of Greenland ; the east coast of Greenland, about 75° N. lat. In the southern hemisphere—The neighbourhood of Cape Horn ; the Kerguelen or Macdonald Islands ; one of the groups south of the Auckland Islands.

I wish that in the influential pages of NATURE this great international scientific subject could be again urged. I cannot help thinking that in the present Hydrographer of the Navy we have an officer who would be at once most able and willing to take part in giving, in the way suggested, true scientific direction and scope to future Arctic research. My confidence in the great value of simultaneous observations in comparison with the meagre results of isolated expeditions must be my apology for thus writing.

E. J. REED

THE NORWEGIAN DEEP-SEA EXPEDITION

FROM soundings taken by the second German Polar Expedition, and kindly communicated by Capt. K[illegible]dewey, of Hamburgh, I have been induced to alter my views about the configuration of the sea-bottom around Jan Mayen. The figure of the bottom which I at present find the most probable I have given in the chart which I send herewith. It will be observed that it is the part of the sea between Jan Mayen and Iceland which is to be corrected on the small chart which was published in NATURE, vol. xvi. p. 527.

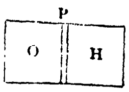


Christiania, October 23 H. MOHN

ON THE DIFFUSION OF MATTER IN RELATION TO THE SECOND LAW OF THERMODYNAMICS

1. THE purpose of this paper is to call attention to a natural process that appears to constitute an exception to the second law of thermodynamics, and which, if noticed by others, would at least appear from its importance to merit a more general recognition. The subject may be best dealt with by means of a simple illustration, the principles involved in the action of which are already perfectly well known.

2. Let the annexed figure represent a cylinder, containing a piston, P; a suitable (plumbago) porous diaphragm (as used for diffusion experiments) being fitted into the piston. The piston can be connected conveniently with any outer arrangement for doing work. Suppose the one half of the cylinder to be filled with oxygen, the other half with hydrogen. Then, as is known, according to the kinetic theory, the molecules of O and H are impinging continually against the porous partition or diaphragm, P, and the molecules in their impacts thus occasionally encounter vacant spaces or pores, and so continue their motion on across the diaphragm into the opposite compartment. Owing, however, to the fact that the molecules of hydrogen are moving four times as fast as the molecules of oxygen, they strike the diaphragm correspondingly more frequently, and thus four times as many hydrogen molecules pass through into division O, as oxygen molecules pass through into division H. [The piston is supposed fixed at present, so that no work being done, there is consequently no heating or cooling of the gas.] But on account of the excess of molecules passing into division O, the pressure there will rise. If, then, after the pressure has risen to a certain degree, the piston be



suddenly released, it will be driven by the excess of pressure in the direction O H, and in that act the gas in O will be chilled and the gas in H heated, which is contrary to the second law of thermodynamics, since in this process work is derived from matter *all at* a uniform temperature, or work is derived by cooling a portion of gas *below the coldest of surrounding objects.* In the same way the piston might have been connected to some external mechanism, and so part of the work be done externally (in a self-acting manner).

3. There can be little doubt that such work is done in natural processes (in the animal and vegetable world) since plants and organic tissues are distinguished for their *porosity*, and such tissues are permeated with the various gases of the atmosphere, carbonic acid, &c. It may be observed that even without any porous diaphragm at all, or when two gases whose molecules possess different velocities are allowed to diffuse into each other, there is invariably a transference of heat, which is contrary to the second law of thermodynamics, which law assumes that heat cannot pass between two bodies originally at the *same* temperature, or heat cannot pass from a colder to a hotter body. Yet it is evident that as soon as the heat has begun to pass from one of the diffusing gases to the other, the one from which the heat commences to pass is already the colder.

4. Such a principle is evidently capable of an enormously wide application in nature. It is only necessary for example for the constituents of the universe to be *diverse*, to get any amount of work by diffusing them together, even if all originally at the *same temperature.* The principle of *the tendency to the uniform diffusion of Matter*, is capable of completely overthrowing *the tendency to the uniform diffusion of Energy;* for even if energy were uniformly diffused, the uniformity could be upset by the diffusion of matter (*i.e.* provided matter were not already all uniformly diffused or homogeneous): and, as we have seen, the quantity of work to be derived by the diffusion of matter is limited only by the quantity of matter at disposal.[1] In order that all capacity for work might cease in the universe, it would be necessary not only that there should be a uniform diffusion of energy, but also a uniform diffusion of matter. Heterogeneity confers a capacity for work, as well as inequality of temperature. Heterogeneity, as far as is known, is one of the distinguishing characteristics of the material universe. Any dissimilarity of molecular mass, which (by equality of temperature) is necessarily attended by dissimilarity of molecular *velocity*, confers a capacity for work. The dissimilarity of *velocity* is evidently the efficient cause in determining the work, and therefore in the exceptional case where dissimilarity of molecular structure is not attended by inequality of mass (and consequently not by inequality of velocity), work could not be derived. We may note, therefore, that inequality of molecular *velocity*, as well as inequality of molecular *energy*, confers a capacity for work, and in order that all capacity for work should cease, not only must molecular *energy*, but also molecular *velocity* be uniformly distributed, or the molecules of matter which (by equality of temperature) possess unequal velocities, must be uniformly diffused.

5. We may observe that gravity which does not interfere with the uniform diffusion of *energy*, does interfere with the uniform diffusion of *matter.* Thus, for example, the energy (heat) of the atmosphere tends to be uniformly diffused throughout a vertical column of the atmosphere, in spite of the action of gravity. But the uniform diffusion of matter (*i.e.*, the uniform mixture of the gases of the atmosphere through each other) is prevented by gravity. For by the well-known law of Dalton (which accords with the result of the kinetic theory of gases), each gas arranges itself as a layer upon the earth's surface, precisely as it would do if no other gas were present. Thus (as is known), owing to [the fact that a greater quantity of nitrogen exists in the atmosphere than oxygen, the nitrogen consequently rises to a greater height than the oxygen, so that at considerable heights the nitrogen predominates. Thus the uniform diffusion of the constituents of the atmosphere through each other is prevented by gravity. It may, perhaps, be just as well to note in connection with this point that those gases which are observed at the surface of nebulæ are not necessarily at the surface because of their greater *lightness*, but this is also determined by *quantity;* for as we have observed, each gas (according to the known conditions of equilibrium) arranges itself about a centre as if no other gas were present; and therefore each gas must penetrate to the centre of the nebula, and therefore could not reach as far as the surface unless its *quantity* were sufficient (though, no doubt, by a greater lightness a less quantity of gas will suffice for that purpose). There might possibly be a tendency to assume (unless the consequences of the above principle were rigidly kept in view) that the light gas observed (such as hydrogen) was floating on the surface of the nebula. We know that according to the conditions of gaseous equilibrium this is wrong, and that each gas (if freed from other disturbing causes) will have its basis at the centre of the nebula, where, therefore, the composition or mixture of gaseous matter is uniform, but nowhere else (excepting in the very improbable case where the quantities and densities of all the gaseous constituents are the same). If gravity were to cease (and the gaseous constituents of the nebula were supposed confined or prevented from expanding), the constituents of the nebula would uniformly diffuse themselves throughout the entire mass, and this act of diffusion would be attended by a transference of heat, even if all the gaseous constituents were at the same temperature.

6. Thus we may observe that by merely modifying the action of gravity or by altering the position of a portion of gas relatively to gravity, work may be derived through diffusion. Thus if we suppose a portion of gas to be moved to different positions in a nebula, the constitution of the portion of gas or the mixture of its constituents is changed according to its position, and in these changes work is derived, or available. Only when the portion of gas is situated at the centre of the nebula are its constituents uniformly diffused through each other; less and less so towards the outside.

7. It would thus appear to follow that, as far as present knowledge goes, a uniform diffusion of *matter* as well as a uniform diffusion of *energy* would be at least required, in order that all capacity for work and physical change should cease in the universe. At the same time does it not rather behove us to look to a time when, through *increase of knowledge*, a means for recurrence may possibly be discovered, whereby physical change is continued, rather than to look to the purposeless end of a chaos of uniform temperature and uniform distribution of matter? Humboldt says relatively to this point (Preface to "Cosmos"): "I would therefore venture to hope that an attempt to delineate nature in all its vivid animation and exalted grandeur, and to trace the *stable* amid the vacillating ever-recurring alternation of physical metamorphoses, will not be wholly disregarded at a future age."

S. TOLVER PRESTON

---

[1] Since the first draft of this paper was written, I have been informed that the question of the quantity of work to be derived by diffusing gases has been treated of by Lord Rayleigh (*Phil. Mag.*, April, 1875), but he does not apparently mention the bearing of the case on the second law of thermodynamics.

MUSIC A SCIENCE OF NUMBERS[1]

THE subject which I submit for your consideration this afternoon is the influence of numbers in music, as in the various combinations of consonances and dissonances which we hear every day, and to show how these are explained by the fundamental laws of the science.

---

[1] Read before the Musical Association of London, November 5, 1877, by W. Chappell, F.S.A.

Although music has appeared to many persons a difficult subject, it is really one of the most easily intelligible and one of the most firmly grounded of sciences. It is purely a science of numbers.

The consonances which charm the ear, such as the octave, twelfth, fifth, fourth, and the major and minor thirds, have two concurrent sets of vibrations; the one set produced by the lower string or pipe, and the other by the upper. Although they vibrate at different rates, yet there are periodical coincidences of vibration between them, and these coincidences sound with much more power upon the ear than the vibrations which are non-coincident, or sound apart. It has been calculated that two hammers striking simultaneously upon an anvil have, through the greater displacement of air, fourfold loudness, instead of merely double. The same law applies to musical sounds. Coincidence of vibration is more briefly expressed by its synonym, "consonance;" and all non-coincident vibrations are included in "dissonances," meaning only that they sound apart. In a musical sense, dissonance is the medium between concord and discord, running from one into the other; for, in the most pleasing intervals, there are some non-coincident vibrations, and when these become very numerous, they overpower all concord. This will be shown in the sequel.

Suppose we take one long pianoforte string or an organ-pipe. The lowest sound it can produce will be that of its whole length, and this may be made the foundation of an entire scale of consonant notes, for every aliquot part of the length, being such as will measure without any remainder, will be also a multiple of the vibrations of No. 1. Thus No. 2, the octave, is half the length and vibrates twice as fast as the whole string. No. 3, the so-called twelfth, or octave and fifth, is a third of the length of No. 1, and it vibrates thrice as fast. Then, if we sound No. 3 with No. 2 instead of No. 1, we throw off the lower octave and have the fifth only, or 3 to 2. It is essential for consonance that the intervals should be aliquot parts of No. 1, for if otherwise, we should only create discord. The musical law is expressed very simply, that the number of vibrations is in inverse ratio to the length of a string.

The scale of all consonances is called the harmonic scale, copies of which are before you. It is exemplified by string or pipe. Let us consider, first, the Æolian harp, on which the winds alone produce the consecutive sounds. The strings are tuned in unison, except the two outmost, one on each side, and those are covered with wire, and tuned an octave lower. When the wind blows quickly enough to sound the bass strings, which we will suppose to have tuned to C on the bass clef, with 128 vibrations in a second of time, it is the whole string which sounds first, and the rapidity of the wind must be doubled before the harp will sound any change of note, and that note will be the octave above the first. It has already been said that the octave is produced by half the length of a string, and that it vibrates twice as fast as the whole—but mark the coincidence between the music and consecutive numbers; 1 and 2 have no note between them, although the sound jumps from the whole length to that of the half! When the bass strings sound the half length they have divided themselves into equal halves by a node, and that node creates tension in opposite directions, the one ventral segment pulling, as it were, against the other. These self-forming nodes may be easily seen by daylight, and at night by throwing a light upon the string. They were shown at our first *conversazione* in these rooms by Mr. Spiller, and at the Edinburgh meeting of the British Association by Mr. Ladd. The gust of wind which sounds the octave, or half length of the bass strings of the Æolian harp, sounds at the same time the whole length of the gut strings, because they are tuned to that pitch. Then, as the wind rises, subdivision goes on in both with every multiple of 128 vibrations for the bass, and of 256 vibrations for the tenor strings.

The reason for tuning the Æolian harp to a low pitch is, that the strings may be more easily acted upon by the wind. We read, poetically, of hanging one in a tree, but it requires a much stronger draught than it will get there, except during a hurricane, when no one will care to go to listen. Our late lamented Vice-President, Sir Charles Wheatstone, F.R.S., fixed a single violin string under a very draughty door, as an Æolian harp, and he calculated the increase of draught caused by lighting a fire in the room, and by the opening of an outer door, by the rising pitch of the note. The varieties produced by this string have been described as "simultaneous sounds," but they were purely consecutive. Anyone may satisfy himself that it could only be so, by repeating the experiment with a good violin string. The change of note is simultaneous with the change of nodes in the string. Mere undulations, or irregularities of vibration, will not change the note, but injure the quality of the tone. All the curves that a string may describe in vibration have been calculated by mathematicians, but only when nodes are formed are they of any importance in music.

Often have I experimented upon harmonics or natural sounds, in former years, and have watched the changes of node, and have heard the simultaneous change of note. The experiments may be tried by any one who has access to a harpsichord, or a very old grand pianoforte. The tension is too great in modern instruments to allow free play to the string. Raise the damper and strike one of the longest uncovered strings with a hard pianoforte hammer near the bridge. The changes follow in numerical order, 1, 2, 3, 4, 5, as in the paper before you, and the sounds ascend by octave, fifth, fourth, major and minor third, harmonic seventh, to the third octave, and then to the major and minor tones. It is difficult to attain the highest of these numbers, but the harmonic seventh, No. 7, is readily distinguished by its unusual sound.

In the Æolian harp the rising pitch of the sounds is caused by the increasing rapidity of the wind; but it is not so on a pianoforte. It is there due to gradual contractions of the string till it ceases to vibrate, and sinks to rest. The vibrations of a long string are widely discursive, but they become gradually more and more contracted as the nodes of the string diminish in length. The point to be remarked is that the sounds jump over intermediate discords—all are consonances—all aliquot parts: all the sounds are multiples of No. 1. It matters not whether it be wind, string, or pipe; in each of them nature teaches us the scale which is to resolve all musical doubts, all disputed chords. She indicates all the basses for musical intervals, the more remote ones adapted only for melody, and the nearest for consonant harmony.

To prove the case further we may take an illustration from a pipe. It must not be from those which have lateral openings, or keys, because they shorten the column of air artificially, but from such instruments as the coach horn, or hunting horn, the so-called French horn, or the trumpet without valves.

The fundamental tone, No. 1, or lowest sound it can produce, is derived from the whole column of air within the tube. To produce No. 2 the rapidity of the breathing must be doubled, and then the column of air within the horn divides itself into two equal halves, and the sound is an octave above; so that, if the first note be tenor C with 256 vibrations in a second of time, this treble C requires to be blown at the rate of 256 vibrations to produce it. Here, again, we arrive at the identification of sounds with numbers; for, just as there is no intermediate number between 1 and 2, so is there no intermediate sound between 1 and 2, its double in vibrations, produced by half its length, upon the horn. The numbers run both ways. They are fractions as to length of tube, and multiples as to vibrations. Again, just as there *is* an intermediate number between 2 and 4 (the second octave), so is there one intermediate sound, and one only; it is No. 3, which is produced by a third of the length of the tube, and is the fifth above No. 2. The fifth and fourth divide the vibrations of the octave equally between them, so that the fifth is three times No. 1, and the fourth immediately above it is four times;—this, notwithstanding the diminution of the musical interval. The names which we have adopted for musical intervals are usually calculated from the keynote, as from C to E a third, from C to F a fourth, and from C to G a fifth, but these names are not real quantities, and are rather confusing than an assistance. The octave is not an eighth, but half, and the double octave is not a fifteenth, but a quarter of the length of No. 1, and vibrates four times as fast. Octaves are powers of 2, thus 2, 4, 8, 16, and 32 are successive octaves. But the octave 4 to 8 has only four sounds, and these are our major and minor third, and two others, divided by the harmonic seventh, which we do not use. From 8 to 16 are eight sounds, of which we use three, the major and minor tones, and the so-called diatonic semitone, as from B to C. It is really the smallest of the eight tones, and not a semitone. The next octave is from 16 to 32, and that is all of semitones, while 32 to 64 is all of quarter-tones. After that, the octave is divided into eighths, sixteenths, and thirty-second parts of tones, among which it is only useful to note (and that only among musicians and mathematicians, that the so-called "comma," having the ratio of 80 to 81, is the eighth of a tone above the third of any key—as it is above E in the key of C. We have lately had mathematicians among us who are not *μουσικοί*, and who have, therefore, proposed to divide an octave into "twelve *equal* semitones." This is pure geometry, and not music. In music there cannot be even two equal semitones within an octave. If our friends will only change their theme from twelve equal semitones into twelve *equally tempered* semitones, and give us their experience of the proposed sounds when heard *with the bass* (which seems not to have yet been taken into account), we shall gladly avail ourselves of their research, on the grounds of modern expediency. In the meantime we must be content to leave the tempering of a scale in the hands of experienced practical men, who, judging only by their ears, as they always will, have hitherto satisfied our immediate requirements.

The interval of a fifth is 2 to 3 in ascending and 3 to 2 in descending, but, as the figures are usually placed over the upper note in scales, the 3 is written above the 2 as in the scale in your hands (the third of them), where it appears over G, referring to C as 2.

And now for the practical use of these figures, for although the harmonic scale may be referred to, they are most easily remembered. All young pupils are taught the difference between an octave, a fifth, a fourth, and a third, upon the pianoforte, and it is only to associate the numbers with those intervals, to find out the best bass, and *every admissible bass*. All octaves are in the ratio of 2 to 1, whether it be 4 to 2, 8 to 4, or 16 to 8. All fifths are in the ratio of 3 to 2, all fourths in that of 4 to 3 all major thirds 5 to 4, and minor thirds 6 to 5.

For instance, in the key of C, C to the F above it is a fourth, and F is No. 4, therefore, the F, two octaves below, is the consonant bass; whereas, if we strike G with the C above, C becomes the natural bass to that interval. The most consonant basses are always found in the lowest numbers, because the proportion of consonant vibrations is there greatest. Thus, from D to C is also a fourth, in the key of C, but the numbers are 9 to 12, with a remote bass in C, and there will be 21 vibrations, of which only two will coincide in every cycle—1 of the 8, with 1 of the 9. Then, the proportion of non-coincidence will be so great as to make the sound unpleasing to the ear. But as 9 to 12 is in the *ratio* of 3 to 4, we have the best bass in these lowest numbers, and take G. By the various basses to intervals we modulate into other keys.

At the International Exhibition, held at South Kensington in 1862, Mr. Saxe, the eminent inventor of Saxe horns, exhibited an immense horn with an exceedingly long coil of tube, and perhaps standing six feet in height. When asked by the jury the object of this excesssive size and length, he answered, "C'est pour jouer dans le cinquième étage"—"It is for playing in the fifth octave," and he produced with facility any of the sixteen tones and semitones of that octave from it. Half the length of any open conical tube is expended upon its second note, the octave. No human power could have blown the low notes of that horn. Supposing it to have been tuned to the lowest C upon the pianoforte, with thirty-three vibrations in a second, as the usual French pitch, it would have had 66, 132, 264, and 528 for its first, second, third, and fourth octaves, while its fifth octave would commence on treble C, with 528, and extend to C above the lines with 1056 vibrations in a second of time. It would thus be within the power of the lungs. He utilized only from the 16th to the 32nd part of his enormous tube, but it gave him the command of the semitones.

This great incumbrance of length is not necessary in a cylindrical stopped tube. It will take up its own octave according to the ratio of its length to its diameter. We have here an example in a resonating tube invented by Charles Wheatstone just fifty years ago. The lecture for which he invented it was afterwards reported in the twenty-fifth volume of the *Quarterly Journal of Science, Literature, and Art*, January to March, 1828. Both he and I knew Eulenstein, an accomplished musician, whose admirable skill in playing upon the Jew's harp was the inducing cause of that particular lecture. Eulenstein had a peculiar facility for contracting and expanding the cavity of his mouth, through the pliability of his very thin cheeks and by the management of his tongue, so that he could fit them for any harmonic note within a certain compass. Wheatstone then gave the law, that a perfect harmonic scale might be drawn from a single tuning-fork, or from the vibrating tongue of a Jew's harp, by resonators adapted, or adapting themselves, to *multiples* of the original number of vibrations. "I took," said Sir Charles, "a tube, closed at one end by a movable piston, and placed before its end the branch [or prong] of a vibrating tuning-fork of the ordinary pitch—C. The length of the column of air [within the tube] was six inches. On diminishing the length of the column of air to three inches [by moving up the piston], the sound of the tuning-fork was no longer reciprocated [in unison], but its octave was produced."

"It is therefore evident from experiments," says he "that a column of air may vibrate by reciprocation, not only with another body whose vibrations are isochronous [or in unison] with its own, but also when the number of its own vibrations is any multiple of the sounding body." Again, he says: "No other sounds can be produced by reciprocation from a column of air, but those which are perfectly *identical with the multiplications* of the original vibrations of the tuning-fork or the tongue of the Jew's harp." I produced the original tube in this room about two years ago, to check a recent theory—that resonators strengthened the ear, and answered only in unison, and Sir Charles ordered this one for me, made by Mr. Groves, under his own superintendence. The improvement in this is, that the piston now works in a groove and is not liable to stick. Two octaves are produced from the tongue of one Jew's harp as rapidly as the piston can be moved up and down. There is no slurring between one sound and another, but clear jumps from one multiple to another, and every one of them may be arrested and heard by itself by checking the piston. But, although I am glad to produce this tube before those who were not present on the last occasion, and to do honour to the memory of our eminent vice-president, who declined to refer in any way to himself, I have another motive also. This is a principle which has never been utilised. We have had pipes stopped at the top, like the usual pitch-pipe, but they have been found too slow in action to be suitable for any other purpose. This is rapidity itself, and might surely be utilised for some such purpose as pedal-pipes for an organ. The piston can be balanced outside to the greatest nicety, and one such pipe will take the scale of C, and another that of F. All that is required is to blow across the top in the manner of the Pandean pipes, or, as it appears, better still, to set free a fan or cogged wheel at the mouth tuned to each of the two fundamental notes. The wheel might be set free by the action of the foot upon the pedal. It is now well known that the length of a 32 or a 16 foot pipe may be greatly reduced by breadth of scale. We Europeans have made little, if any, use of resonators, and yet they have been long in use in Java. The drawing on the wall is of an instrument brought from Java by Sir Stamford Raffles more than half a century ago. There is one of the same kind in the British Museum. But this is perhaps of greater interest, as it may have suggested to Wheatstone the *principle* of the resonating tube. The natives of Java cast metal plates which they suspend in a row upon strings, and strike them with drum-sticks, which are fitted into circular heads. As all cast metal is more or less false in tone, owing to inequalities and lack of homogeneity, they place some of the largest bamboos, cut to short lengths, and placed upright, under the metal to make the true sounds of these resonators to overcome the false harmonics of the metal plates.

Resonators were used in the theatres of ancient Greece—we here find them used in Java; but these powerful auxiliaries to tone still await their development in modern Europe.

And now, in conclusion, permit me to draw your attento a harmonium with two keyboards, the upper one having four octaves of our scale tuned without tempering, and the lower with the five octaves of the harmonic scale, and the sixteen notes in the fifth octave. Much has been said of the harmonic scale, and this is perhaps the only instrument on which the harmonics can be fully heard and sustained for experimental use.

ROBERT SWINHOE, F.R.S.

WITHIN the last thirty years or so their respective vocations happen to have called two able lovers of natural history in the direction of the Celestial Empire—Mr. Robert Swinhoe, from England, and the Père Armand David, a Frenchman. The simultaneous investigations of these two biologists have added immensely to our knowledge of a country whose fauna not long ago was thought to be in no way interesting, because the huge population had succeeded in extirpating all the indigenous species. How far from the truth such an assumption is, has been demonstrated by the researches of the two naturalists above mentioned, the lamented death of the former of whom, at the early age of forty-one years, we recorded last week.

Mr. Swinhoe was born at Calcutta on September 1, 1836, and was educated at King's College, London, whence he matriculated at the University of London, in 1853. The next year he went, as supernumerary interpreter, to Hong Kong, being transferred to Amoy in 1855, and to Shanghai in 1858. In the same year he was attached to the Earl of Elgin's special mission to China, and afterwards to H.M.S. *Inflexible* as interpreter in a circumnavigating expedition round Formosa, in search of certain Europeans said to have been held in captivity at the sulphur mines on the island.

In 1860 Mr. Swinhoe attended Gen. Napier, and afterwards Sir Hope Grant, the Commander-in-Chief, as interpreter, and received a medal for war service. At the end of the same year he was appointed Vice-Consul at Taiwan, Formosa, and in 1865 to the full Consulship. In 1866 he was Consul, temporarily, at Amoy, and in 1868 went to explore the Island of Hainan. From May, 1871, to February, 1873, he was acting Consul at Ningpo, and at Chefoo until October of the latter year, when he had to retire from the service, on account of increasing paraplegia, from which he died on October 28 last.

Mr. Swinhoe was a Fellow of the Asiatic Societies of China and of Bengal, as well as of many other societies, having been elected into the Royal Society in 1876.

By far the majority of Mr. Swinhoe's scientific communications—fifty-two in number—mostly on the mammalia and birds of China, are to be found in the *Proceedings* of the Zoological Society of London between 1861 and 1874. Other papers appeared in the *Ibis* and the *Annals and Magazine of Natural History* within the same period. Among the most important of these are the "Catalogues" of the mammals and birds of China and its islands, in which are to be found descriptions of many new species of both classes, among which are St. John's Macaque (*Macacus sancti-johannis*), the Water Deer of Shanghai (*Hydropotes inermis*), the Mantchurian Deer (*Cervus mantchuricus*), the Orange-bellied Helictis (*Helictis subaurantiaca*), the Superb Flying Squirrel (*Pteromys grandis*), Boyce's Stork (*Ciconia boyciana*), together with a great number of other birds, for a complete account of which we cannot do better than refer our readers to a work upon the birds of China, by M l'Abbé David and M. E. Oustalet, published at Paris a week ago.

Michie's Deer (*Lophotragus michianus*) is the name given by Mr. Swinhoe to a small deer from Ningpo, with antlers more diminutive than many other species. This, or a very closely-allied species, was previously sent to Paris by Père David, and described by M. A. Milne-Edwards under the name *Elaphodus cephalophus*.

Mr. Swinhoe, besides the collections which he made, was indefatigable and particularly successful in his endeavours to send living animals from China to this country, and there are many species, including *Cervus swinhoii*, *Hydropotes inermis*, and *Ciconia boyciana*, which were first procured by him

It will be some time, we fear, before so enterprising a naturalist as Mr. Swinhoe takes up his residence in China, and employs every available opportunity for the prosecution of his favourite line of research.

DOUGLAS A. SPALDING

OUR readers must be familiar with this name as that of an occasional contributor to NATURE of thoughtful and acute articles in the department of mental science; they will be sorry to hear—but those who knew him will not be surprised—that Mr. Spalding died on October 31, at Dunkirk, just as he was preparing to go to the Mediterranean coast to spend the winter. Not much is known of Mr. Spalding's early life, but we are told by one who ought to know that his parents, belonging to Aberdeenshire, were in very humble circumstances, and that he was born in London about the year 1840. He himself spent his early years in Aberdeen as a working slater, doing his best to educate himself. By the kindness of Prof. Bain Mr. Spalding was allowed to attend the classes of Literature and Philosophy in Aberdeen University free of charge, in the year 1862. After that he got some teaching about London, and worked very hard to support himself, and even managed to keep his terms as barrister, though he never practised. It was during this period of privation that he contracted disease of the lungs, from which he suffered greatly up to the time of his premature death. The first thing that brought him to the notice of the scientific world was his experiments on the instinctive movements of birds, which were first described at the Brighton meeting of the British Association in 1872, and published in *Macmillan's Magazine* for February, 1873. From a series of interesting experiments on chickens he showed that the only theory in explanation of the phenomena of instinct that has an air of science about it is the doctrine of inherited association. Instinct, he maintained, in the present generation of animals, is the product of the accumulated experiences of past generations. In another paper at the Bristol meeting of 1875 he communicated the results of further experiments, some described in NATURE, vol. viii. p. 289, bearing out still more strongly the conclusions he had already reached, and which he summed up in the statement that "animals and men are conscious automata." The Brighton paper brought Mr. Spalding into deserved repute. While travelling in France he became acquainted with John Stuart Mill, and through him afterwards with many other distinguished men, who all treated Spalding with great respect. Through Mill also, we believe, he became acquainted with Lord and Lady Amberley, with whom he lived as companion and tutor to their children from 1873 until the death of Lord Amberley. Mr. Spalding was appointed guardian to the children, but was ultimately compelled to withdraw from this office owing to his religious opinions, Earl Russell, however, allowing him to retain for life the salary settled upon him by Lord Amberley. For the last two years Mr. Spalding has lived mostly in the south of France, bearing his fatal and protracting illness with the greatest equanimity, regretting only his powerlessness to work and his enforced absence from London.

As to the value of his scientific work our readers having the material before them are able to judge. By his experiments on animals he did much not only to clear up the nature of what is called instinct, but also to shed a new light on certain mental phenomena in man himself. His papers in NATURE, mostly reviews of works connected with psychology, on the metaphysics of instinct and evolution—of the latter doctrine he was a warm advocate—were good specimens of clear and close reasoning. That he had a tender side to his character is evident from even his Association papers, and still more so from the interesting letters written by him to NATURE, last April, on the swallows and cuckoos at Menton. All who knew him felt that had his health permitted he would have added largely to scientific knowledge in the special department to which he had devoted himself—physiological psychology.

OUR ASTRONOMICAL COLUMN

THE SOLAR ECLIPSE OF 1878, FEBRUARY 2.—The eclipse of the sun in February next will be annular, but the central line passes at such high southern latitudes that the annular phase is not likely to be observed unless it be in the western parts of Tasmania near sun-set. Thus the central eclipse will commence in longitude 103° 0′ west of Greenwich, latitude 73° 8′ south, and will end in longitude 149° 25′ east, latitude 40° 58′, and the eclipse is central at noon in longitude 112° 27′ west, and latitude 84° 3′ south. Another point upon the central line is in longitude 145° 25′ east, and latitude 42° 25′, where the sun's altitude, however, will be less than 4° ; this point lies on the west coast of Tasmania. Launceston is near the central line, but at the middle of the eclipse the sun at that place is almost in the horizon.

A large partial eclipse will be visible over the southern parts of Australia. At Melbourne it will commence at 6h. 1m. P.M. local mean time, at 120° from the sun's north point towards the west, and will attain its greatest magnitude 0·91, just before sunset, or at 7h. 4. At Adelaide the eclipse will begin at 5h. 44m. local time and will be greatest about 6h. 45m., when the magnitude will be 0·85, with the sun at an altitude of between 5° and 6°. At Perth, in Western Australia, the whole eclipse will be visible; greatest about 5h. 25m. local time, magnitude 0·66, with the sun at an elevation of 23°.

The next *total* eclipse of the sun visible in those parts of the earth will take place on the morning of September 9, 1885. At Wellington, New Zealand, the eclipse begins about a quarter of an hour after sunrise; totality commences at 7h. 42m. A.M., but continues only about forty seconds; in 175° 3′ east, and 40° 34′ south, on the central line, the duration of totality is 1m. 54s. It should be stated that these figures are founded upon the tables of Damoiseau and Carlini.

THE MINOR PLANET EUPHROSYNE.—It does not frequently happen that we have to look for a planet at 60° of north declination; such, however, will be the case at the end of the present year, and in the first days of 1878 as regards Euphrosyne, No. 31 of the group, which was discovered by Ferguson at Washington, on September 1, 1854. The planet will be in opposition on December 18, with the brightness of a star of the tenth magnitude. The following are its calculated positions when passing its greatest northern declination.

12h. Berlin M.T.		Right Ascension. h. m s		Declination. ° ′ ″		Distance from the Earth.
1877, December 31	...	5 20 17·1	...	60 2 56	...	1·613
1878, January 1	...	5 18 49·5	...	60 2 59	...	1·614
,, ,, 2	...	5 17 24·1	...	60 2 38	...	1·618

The star L. 10067 in Camelopardus, which Lalande calls an eighth, and Argelander a seventh, will be a good guide for identifying the planet in this position. At midnight at Greenwich on January 1, by calculation, Euphrosyne will precede the star seven seconds in R.A., seven minutes to the south of it.

The latest elements of this body which, it will be seen, approaches much nearer to the pole of the equator than the generality of the small planets, are as follows, according to the computations of Mr. S. W. Hill:—

Epoch 1877, December 18 0 M.T. at Berlin.

		° ′ ″
Mean Longitude	... .	90 10 23
Longitude of Perihelion	... ...	93 17 30
,, Ascending Node	... ...	31 33 23
Inclination	... ...	26 28 34
Eccentricity	... .	0·222786
Semi-axis major	... ...	3·14902

COMETS OF SHORT PERIOD IN 1878.—Of the comets known to be performing their revolutions in periods of less than ten years, two are due in perihelion again in the ensuing year, probably within a few days of each other. According to Dr. von Asten's elements of Encke's comet at its appearance in 1875, the next perihelion passage, neglecting perturbation, would fall about July 27·0, which involves an apparent track in the heavens unfavourable for observation. In 1845, when the conditions were more nearly the same than at any of the comet's returns since its periodicity was first ascertained, only four observations were secured between July 4 and 14—at Rome, Philadelphia, and Washington. If the comet is not observed before the perihelion in 1878, while at a considerable distance from the earth, it may be found at the observatories of the southern hemisphere, after perihelion, or in the latter part of August, when it makes its nearest approach to us, although its distance at that time will not be less than the mean distance of the earth from the sun. The second comet, which is due in perihelion in 1878, is that discovered by Dr. Tempel on July 1, 1873. The period of revolution assigned by Mr. W. E. Plummer from observations extending to October 20, is 1,850 days; and the comet, neglecting perturbations which are not likely to be material, would be in perihelion again about July 20; this date, however, will be uncertain, as thus far no definite discussion of the observations in 1873 has been published. Some time since it was stated that Herr Schulhof, of the Vienna Observatory, was at work upon this comet. With the above date for perihelion passage, the apparent path would be favourable for observations, and the comet would approach the earth almost as closely as is possible with the actual form of orbit.

NOTES

THE session of the Royal Society opens next Thursday with the Bakerian Lecture On the Organisation of the Fossil Plants of the Coal Measures, Part ix., which will be delivered by Prof. W. C. Williamson, of Manchester, F.R.S.

WE learn from the *Times* that the following is the list of the new Council which will be submitted to the Royal Society for election at their anniversary meeting on St. Andrew's Day next, the 30th instant:—President, Sir Joseph Dalton Hooker, C.B., K.C.S.I., M.D., D.C.L., LL.D.; Treasurer, William Spottiswoode, M.A., LL.D.; Secretaries, Prof. George Gabriel Stokes, M.A. D.C.L., LL.D., Prof. Thomas Henry Huxley, LL.D.; Foreign Secretary, Prof. Alexander William Williamson, Ph.D.; other members of the Council—Frederick A. Abel, C.B., V.P.C.S., William Bowman, F.R.C.S., Frederick J. Bramwell, M.I.C.E., William B. Carpenter, C.B., M.D., LL.D., William Carruthers, F.L.S., William Crookes, V.P.C.S., Prof. P. Martin Duncan, M.B., F.G.S., William Farr, M.D., D.C.L., Prof. William H. Flower, F.R.C.S., Prof. G. Carey Foster, B.A., F.C.S., John Russell Hind, F.R.A.S., Lord Rayleigh, M.A., Vice-Admiral Sir G. H. Richards, C.B., Prof. Henry J. Stephen Smith, M.A., Prof. Balfour Stewart, M.A., and Prof. Allen Thomson, M.D., F.R.S.E.

MR. F. M. BALFOUR, Fellow and Lecturer of Trinity College, Cambridge, has joined the editorial staff of the *Quarterly Journal of Microscopic Science*. The journal will in future be conducted by Prof. Ray Lankester as responsible editor, with the co-operation of Mr. Archer in Dublin, Mr. Balfour in Cambridge, and Dr. Klein in London. The volume for the year just concluded shows an increase in the number and efficiency of the lithographic plates. Instead of sixteen octavo plates as usual four years ago, there are twenty-five, many of which are double sized, and some coloured.

MADAME LEVERRIER, the widow of the astronomer, died on November 1, at the age of fifty-eight years. This lady was suffering from a protracted illness, when the loss of her husband produced a shock from which she was not able to recover. She was a daughter of M. Choquet, an eminent professor of mathematics in Paris. Her father, about eighty years old, was present at the funeral. On the very day that Madame Leverrier died, the *Journal Officiel* published a decree, signed by M. Brunet, the Minister of Public Instruction, ordering the bust of Leverrier to be placed in the Palace at Versailles, where are to be collected the memorials of the great Frenchmen of the nineteenth century. This honour has been decreed to a number of other men who have ranked foremost amongst *littérateurs*, artists, or politicians. M. Leverrier, it is strange to say, has been chosen as the only representative of science.

THE French Academy of Medicine has been authorised by the ministry to accept a legacy of 4,000*l*. bequeathed by Dr. Demorquay, to help them to build a hall of meeting.

M. FAYE, Inspector-General in Science of Secondary Education in France, has been appointed to a similar office for superior education in succession to the late M. Leverrier. M. Fernet has succeeded to M. Faye's post.

M. WATTEVILLE, director of Arts and Sciences in the French Ministry of Public Instruction, has issued a circular notifying that a special exhibition will be held at the Champ de Mars, for collecting the results of the scientific missions granted by the French Government in 1867. Almost every country, civilised and barbarian, near or remote, has been visited.

M. BERTRAND, the perpetual secretary of the French Academy of Sciences, has been appointed by M. Bonnet member of the International Metric Commission.

COMMANDER GUISEPPE TELFENER has announced his intention of placing at the disposal of the Italian Geographical Society a sum of 40,000 francs to found a section of commercial geography and organise at Rome a museum to contain specimens of all the products which Italy exports and imports.

AT a meeting held at the London Library on October 26 (Mr. Robert Harrison in the chair), it was determined to form an Index Society, with the immediate object of compiling subject indexes and indexes of standard books of facts, to be printed and circulated among the members; and with the ultimate object of building up a general index of universal literature, which can be referred to at the office of the society during compilation. The great aim of the society will be the gradual accumulation of aids towards the preparation of a key to all knowledge, and with this object a library of indexes will be commenced. The subscription will be one guinea. Subscribers' names and suggestions on the subject of the proposed society will be received by Henry B. Wheatley, hon. sec. *pro tem.*, 5, Minford Gardens, West Kensington Park, W. The utility of such a society and such an index to scientific men of all classes and grades will be obvious, and the effort now being made deserves their hearty support.

THE system under which the official addresses are made at the annual meeting of the American Association for the Advancement of Science seems curiously complicated, and sometimes is a puzzle even to the old members of that body. The retiring president, who has been the presiding officer in the preceding year, makes the opening address, which is the presidential address for that year. The presidents of the sections, on the other hand, who have just entered on their duties, open their sections respectively with an address. There are only two sections, A and B; other divisions are parts of these, and are characterised as sub-sections. Section A has charge of mathematics, astronomy, physics, chemistry, and microscopy; Section B of zoology, botany, geology, palæontology, ethnology, and archæology. There is a further complication in the circumstance that the presidents of the sections are also the two vice-presidents of the Association. To illustrate this arrangement, we may cite proceedings at the meeting of last August at Nashville. Prof. W. B. Rogers, who was the president of the Association last year, and president at the Buffalo meeting, was expected to open the Nashville meeting with the presidential address, but was prevented by illness. Professors E. C. Pickering and O. C. Marsh are respectively presidents for the present year of Sections A and B, and also vice-presidents of the Association. The address on "The Introduction and Succession of Vertebrate Life in America," by Prof. Marsh, which we recently published in full, was his official address as the president of Section B, delivered at the opening of the Section. To carry the illustration further, it may be added that Prof. Marsh, who was elected at this year's meeting, president of the Association, will not preside till next year at St. Louis, and will not be expected to deliver his presidential address until the meeting of the following year, 1879.

THE death is announced of Dr. Henry Lawson, until recently editor of the *Popular Science Review*.

MR. JAMES FLOWER, for many years the articulator of the skeletons at the Royal College of Surgeons, has just died from carcinoma of the rectum, from which he had been suffering for some time past. Mr. James Flower was seventy-seven years of age, and had served in the army in his younger days.

FROM statements made at a meeting of the California Academy of Sciences, the eucalyptus tree may be enumerated among the means for checking fire. Eucalyptus shingles are said to be fire-proof. A tree of this species was exposed to the San Francisco fire of 1876, and is still flourishing. The notion is urged that the spread of fires in cities could be checked by setting out such trees for shade and ornament. All varieties of the eucalyptus are said to possess this valuable property.

THE first examination of Surveyors and Inspectors of Nuisances by the Sanitary Institute of Great Britain, took place on Monday, October 29. Eight candidates presented themselves, five of whom were successful in obtaining certificates of competence, namely, Mr. H. M. Robinson, Surveyor, Ulverston; Mr. J. Parker, ditto, Bridgwater; Mr. F. Booker, Inspector of Nuisances, Bradford; Mr. W. S. Prebbles, ditto, Blackburn; Mr. Thomas Blanchard, ditto, Evesham. Fifteen candidates have already entered their names for the next examination.

NEWS has been received, the *Geographical Magazine* states, from M. Kelsief, who has been making researches during the past summer along the Murmanian coast and in Lapland, for the Moscow Anthropological Exhibition of 1870. M. Kelsief had been travelling with M. Singer, secretary of the Natural History Society; and the two had, up to the time of their parting company on the borders of the White Sea, made a good collection of stone implements and other prehistoric remains, M. Kelsief then took a cruise in a small vessel, and traversede with considerable difficulty, about 800 versts in all in the White and Polar Seas, and passed the whole of the summer within the Arctic circle. Along the Murmanian coast he visited the Lapps, who inhabit there subterranean dwellings, grouped at intervals of between 70 and 100 versts. He was accompanied by only one servant, and after enduring considerable hardships through exposure and insufficiency of food, he started on August 29 for the north of Finland, where he proposes to visit the Lapps of Lake Enara, and to return to St. Petersburg by way of Tornea.

THE portion of the Indus River where it emerges from Kashmir territory and flows through the mountainous region of Gilgit and Chilas to rejoin our frontier near Darband—a strip in all of about 120 miles in length—has just received, we learn from the *Geographical Magazine*, detailed exploration at the hands of a Punjab surveyor. This piece of work will complete our geographical knowledge of this river, and will contribute useful topographical information to our future maps, though it must be remembered that the general course of the river had been pretty accurately determined in 1870 by Capt. Carter's careful triangulation of the peaks flanking its eastern and western banks.

THE London papers contain frequent announcements of expected high tides, which are no doubt useful to many as fore-warnings of danger. But we cannot understand why the burden of such predictions should fall solely upon Capt. Saxby. Is he the only one qualified and concerned to make such predictions?

WE have received a reprint of four important papers which originally appeared in the *New York Tribune*, and which are now sold separately by that paper at the insignificant price of 10 cents. The papers are on the Evolution of Life, by Dr. Draper; Ancient Life in America, by Prof. Marsh; Catastrophism and Environment, by Mr. Clarence King; and the Peabody Museum (illustrated), by Mr. Wyckoff. This is No. 37 of these science numbers of the *Tribune*; evidently, then, it is the interest of the management to find space foi so much science.

A COMMITTEE has been formed in Holland under the patronage of Prince Henry of the Netherlands, and 24,000 florins have been collected, to send out in May of next year a small but strong sailing vessel to the west coast of Spitzbergen, with the view of reaching the mouth of the Yenissei. The objects of the expedition are to explore the new commercial route to the Siberian rivers, to train sailors who might ultimately be intrusted with the formation of a scientific station, and to erect a few monuments to the memory of the early Dutch arctic navigators.

THE celebrated mammalian and reptilian remains obtained by Mr. Beckles from the base of the middle Purbecks at Durdlestone Bay, and described by Prof. Owen in the Palæontographical Society's *Memoirs* were acquired last year by the British Museum. Under the care of Mr Davis they have been carefully cleaned, mounted, and labelled, and are now being placed in cases. The total number of specimens acquired was about 2,000, but only some of the best are exhibited.

THE tank prepared at the Westminster Aquarium for the whale is now used as a seal pond. Its large size gives ample scope for the gambols of the young seals, which can now be seen under circumstances more favourable than have before been offered in London.

MR. O. H. A. MOGGS writing to the *Times* from Bullpits, Bourton, Dorset, states that that place was visited on Friday last by what seemed to be two shocks of an earthquake. The first occurred at about 8.10 A.M., and was accompanied by a rumbling sound, which lasted about ten or twelve seconds. The vibration of the ground was very slight, although it could be distinctly felt. The second shock was felt at 11.20 A.M. The vibration of the ground was very violent, causing houses to shake and the windows to rattle. This lasted about six seconds, and was accompanied by a rumble like the former, only heavier, which lasted about eight or ten seconds.

A SLIGHT shock of earthquake was felt on Sunday afternoon at New York. It was also felt in New Brunswick and Quebec.

MESSRS. J. AND A. CHURCHILL have published in a separate form, for the use of students, the valuable "Notes on Embryology and Classification" by Prof. Lankester, from the current number of the *Quarterly Journal of Microscopical Science*.

UNDER the title of "The Lazy Lays and Prose Imaginings, written, printed, published, and reviewed by William H. Harrison," of Great Russell Street, the author has published a collection of verse interspersed with short prose pieces partly sentimental but mostly intended apparently to be funny. Scientific men and matters are in one or two cases alluded to, and the imprint bears that the work is published "A.D. 1877 (popular chronology); A.M. 5877 (Torquemada); A.M. 50,800,077 (Huxley)." We believe our readers may derive a little amusement from a perusal of the volume.

THE additions to the Zoological Society's Gardens during the past week include an Anubis Baboon (*Cynocephalus anubis*) from West Africa, presented by Mr. Ward; a Macaque Monkey (*Macacus cynomolgus*) from India, presented by Dr. W. B. Stirling; a Grey Ichneumon (*Herpestes griseus*) from India, presented by Mrs. Henry Jephson Mello; a Central American Agouti (*Dasyprocta isthmica*) from Central America, presented by Mr. A. Stradling; three Sclater's Curassows (*Crax sclateri*) from Paraguay, presented by Mr. Alex. F. Baillie; a Puff Adder (*Vipera arietans*) from South Africa, presented by Mr. A. Biden; a Pike (*Esox lucius*) from British Fresh Waters, presented by Mr. A. D. Bartlett; an Axis Deer (*Cervus axis*) from India, a Three-banded Armadillo (*Tolypeutes conurus*) from La Plata, deposited; a Cape Buffalo (*Bubalus caffer*), two Coatis (*Nasua nasica*), born in the Gardens.

AMERICAN SCIENCE

THE chief signal officer of the U.S. army has been urging that physical observations of the sun be made, as of sun-spots, faculæ, protuberances, &c., in reference to their supposed influence upon terrestrial meteorology, and has offered to publish the results monthly, or such of them as may be considered desirable by the observer, in the *Monthly Weather Review*. The United States Naval Observatory at Washington has already accepted this proposition, and it is considered very desirable that some other observatories in the east, and at least one on the western coast, co-operate in this undertaking.

Dr. C. A. White, palæontologist to the United States Geological and Geographical Survey of the Territories, has spent the past season making a critical study of the mesozoic and cainozoic strata of the great Rocky Mountain Region, and the results have tended to confirm in a remarkably clear manner the statement often expressed by Dr. Hayden in his annual reports, that the entire series of deposits are consecutive from the Dakota group of cretaceous age below, to the Bridger group of tertiary age above. The sedimentation was evidently continuous through all the changes, from marine to brackish, and from brackish to fresh waters, that successively took place in that great region, although those changes in aqueous conditions produced corresponding changes in the then prevailing forms of invertebrate life.

The annual report of the Board of Regents of the Smithsonian Institution for 1876 has been published, and, as usual, contains a great deal of matter interesting to men of science. The portions of the volume detailing the operations of the institution for 1876 is more especially occupied with an account of what was done in connection with the International Exhibition of 1876, at Philadelphia, and especially of the very extensive and valuable presents made to the United States by the various foreign commissions, and taken charge of by the institution, in accordance with the law of Congress. Reference is made to an application for an appropriation to erect an additional building to accommodate these objects, for which it is estimated that a floor space of 80,000 square feet will be required. Until this is done the collections in question must remain in their original packages, more than 4,000 in number, which are stored on four floors of a separate building, 50 by 100 feet, and filling them completely from floor to ceiling. As usual, the funds of the institution are reported as being in a favourable condition, the income not being exceeded by the expenditure, and an available balance even remaining in hand at the end of the fiscal year. The second part of the volume embraces biographical notices of Dom Pedro II., and also of Gay-Lussac, articles on the kinetic theories of gravitation, the revolutions of the crust of the earth, the asteroids between Mars and Jupiter, and a number of papers on ethnology and archæology. Of these the most important is by Prof. Mason on the Latimer collection of antiquities from Porto Rico, in which the more interesting objects of this unique series are figured. Other papers on ancient mines and mounds, implements of various kinds, &c., are also contained in the volume.

We have to record the death of Mr. Timothy Abbott Conrad, one of the oldest and most accomplished palæontologists of the United States. Mr. Conrad was born in 1803, and commenced his investigations early in the century, beginning with the tertiary and cretaceous formations of the United States. In 1832 he commenced an illustrated work on the "Fossil Shells of the Tertiary Formations of the United States," which was, however, preceded in 1831 by his "American Marine Conchology." Most of his papers appeared in the *American Journal of Science and Arts*, and in the *Proceedings* and *Memoirs* of the Academy of Natural Sciences, Philadelphia. He also contributed largely to the reports of the various government exploring expeditions.

The Nation announces the death of Mr. John G. Anthony, for many years a devoted coadjutor of Agassiz in the Museum of Comparative Zoology at Cambridge, where he had charge of the conchological department. Long residence and extensive travel in the Ohio Valley had made him the first authority in the United States on fresh-water shells. He accompanied the Thayer expedition to Brazil, but sickness prevented him from taking part in it after its arrival. In addition to his special work Mr. Anthony always maintained an interest in Botany and horticulture. He was a native of Rhode Island, and was in the seventy-fourth year of his age.

Prof. Marsh makes the announcement of the interesting discovery of the remains of two species of fossil bison in the lower pliocene of Nebraska and Kansas. They were much larger than the existing bison, with more powerful horns.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIDGE.—The Vice-Chancellor, Dr. Atkinson, on resigning his office on November 3 (he has been re-elected) spoke of the progress of scientific teaching in the University. The efficiency of the University as a school of natural science has been greatly promoted, Dr. Atkinson stated, during the past year by the erection of the new buildings for the department of comparative anatomy and physiology. Although the whole building is not yet completed, many of the rooms are already in use, and the accommodation which is thus provided for both teachers and students will be of the greatest advantage. In connection with this subject Dr. Atkinson referred to Prof. Clerk Maxwell's announcement that His Grace the Chancellor has now completely equipped the Cavendish Laboratory with all the apparatus and instruments which the professor considers that a first-class institution of this kind ought to possess. This singular munificence, continued so steadily and ungrudgingly for such a number of years, is but one of the many proofs which His Grace is constantly giving of his unwearied care and concern for the welfare of the University.

The following gentlemen have been elected to fellowships at St. John's College:—Arthur Milnes Marshall, B.A., Senior in Natural Science Tripos, 1874, and Donald M'Alister, B.A., Senior Wrangler and First Smith's Prizeman, 1877.

OXFORD.—AT a special meeting of the Town Council held at Oxford on Monday it was resolved to establish a first-class grammar school, the Corporation granting a site in the centre of the city of nearly an acre in extent, 4,000*l.* towards the building, and 100*l.* per annum towards its maintenance. There are to be fifty free scholarships tenable for three years, thirty of which are to be filled up from the public elementary schools.

LONDON.—The Council of University, College, London, have appointed the Rev. T. G. Bonney, B.D., of St. John's College, Cambridge, Professor of Geology and Mineralogy for five years.

ST. ANDREWS.—Mr. George Chrystal, B.A., Fellow and Lecturer of Corpus Christi College, Cambridge, has been appointed to succeed Prof. Fischer in the chair of mathematics.

Among the names likely to be brought forward by the students for the honorary and honourable post of rector of the University, that of Prof. Tyndall is mentioned.

SCIENTIFIC SERIALS

Morphologisches Jahrbuch, vol. iii. Part 3.—R. Bonnet, on the structure of, and circulation in, the gills of Acephala, pp. 45, three plates.—C. Hasse, fossil vertebræ (the Squatinæ), two plates.—R. Wiedersheim, the skull of Urodeles, pp. 97, five plates; a most valuable memoir on Menobranchus, Siren, Proteus, Amphiuma, Cryptobranchus, Menopoma, Salamandrina, Triton, Axolotl, Plethodon, Spelerpes, Ellipsoglossa, Amblystoma.—M. Fürbringer, on the cephalic skeleton of Cephalopods.

Annalen der Physik und Chemie, No. 9.—On discontinuous liquid motions, by M. Oberbeck.—Explanation of Dufour's and Merget's experiments on the diffusion of vapours, by M. Kundt.—On the diffusion of liquids, by M. Johannisganz.—On the internal friction of solid bodies, by M. Schmidt.—On the photo-electricity of fluorspar, by M. Hankel.—On the resistance of flames to the galvanic current, by M. Hoppe.—On the electro-chemical process at an aluminium anode, by M. Beetz.—Further experiments on galvanic expansion, by M. Exner.—Reply to Zöllner's objections against my electro-dynamic views, by M. Clausius.—On a mode of inference employed by Prof. Tait in the mechanical theory of heat, by M. Clausius.—On the sounding of air in pipes, by M. Ciamician.—The spectrum of nitrous and hyponitric acid, by M. Moser.—On optical illusion, by M. Trappe.

Beiblätter zu den Annalen, &c., No. 8.—On the equilibrium of a drop between two horizontal plates, by M. Bosscha.—On cylindrical sound-waves, by M. Grinwis.—Application of the galvanic current to investigation of the spheroidal state of some liquids, by M. Hesehus.—On the tenacity of copper and steel, by MM. Pisati and Saporita Ricca.—On the polymorphism of crystals, by M. Moutier.—The heat of solution of chlorine, bromine, and iodine compounds, by M. Thomsen.—New saccharimeter, by M. Laurent.—Lecture experiment on the colour-change of certain double iodides, by M. Boettger.

No. 9.—On physical isomerism, by M. Lehmann.—On the elasticity of gypsum and mica, by M. Coromilas.—On the influence of pressure on the temperature at which water shows a maximum density, by M. Van der Waals.—Apparatus for measurement of the expansion of rigid bodies by heat, by M. Reusch.

SOCIETIES AND ACADEMIES

LONDON

Chemical Society, November 1.—Dr. Gladstone in the chair.—The following papers were read:—On some hydrocarbons obtained from the homologues of cinnamic acid, by W. H. Perkin. These hydrocarbons were prepared either by heating the acids or by treating the hydrobromo acids with bases. The following acids were prepared and examined:—Hydrobromocinnenylacrylic, hydrobromocinnenylcrotonic, hydrobromocinnenylangelic. The following hydrocarbons were obtained:—Isopropylvinylbenzene, isopropylallylbenzene, isopropylbutenylbenzene, allylbenzene, and butenylbenzene; the dibromides of these bodies were also prepared and examined.—On anethol and its homologues, by W. H. Perkin. By heating methylparoxyphenylacrylic acid, vinylic anethol was obtained, similarly allylic or ordinary anethol and butenylic anethol were prepared. In conclusion the author discusses the formation of the hydrocarbons from the hydrobromo acids, and concludes that they are formed simply by the separation of hydrobromic acid and carbonic anhydride.—On two new methods for estimating bismuth volumetrically, by M. M. P. Muir. To a solution of bismuth in nitric acid an excess of sodium acetate is added, and then a measured volume of standard sodium phosphate solution also in excess; the bismuth is precipitated, the precipitate filtered off, and the excess of phosphoric acid determined in the filtrate by uranium acetate. The other method given does not yield such accurate results.—On the oxidation of ditolyl, by T. Carnelly. By the oxidation of solid ditolyl the author obtained diparatolylphenylcarbonic acid and diparadiphenyldicarbonic acid; liquid ditolyl yielded orthoparatolylphenylcarbonic acid, orthoparadiphenylcarbonic acid, and finally terephthallic acid.—On a new manganese reaction, by J. B. Hannay. If a solution of a manganous salt in strong nitric acid is warmed in the presence of an iron salt with some crystals of potassic chlorate, the iron and manganese are precipitated as a double manganate of iron and manganese. The author proposes this reaction for separating iron from aluminium, &c.

PARIS

Academy of Sciences, October 29.—M. Peligot in the chair.—The following papers were read:—*Résumé* of a history of matter (second article), by M. Chevreul.—On the solar photospheric system, by M. Janssen.—The telephone of Mr. Graham Bell, by M. Breguet.—On the determination of the quantity of mud contained in current water, by M. Bouquet de la Grye. He uses an instrument named a pelometer (πῆλος, mud), consisting of a V-shaped vessel whose rectangular faces, inclined one-tenth, are of thin glass, while its sides are of copper or white iron. One glass face has a centimetre scale commencing from the angle. The pelometer is filled and held vertical; it then presents a succession of vertical layers of increasing thickness upwards, and, by comparison with glass-ended tubes containing muddy water of various known densities, the proportion of mud may be ascertained. Other methods are given. Experiments made at Rochelle show that the quantity of mud per litre varies from one to ten times according to the depth. He considers regular measurements of the kind on watercourses desirable for agriculture, &c.—On an American vine-stock not attacked by phylloxera, by M. Fabre. This vine belongs to the species *Riparia*. Among other merits (besides its immunity) it gives cuttings readily, receives grafts from French species better than any other American variety, thrives in most arid soils, compact clays, and soils long exhausted by vine cultivation, and grows very rapidly.—On treatment of phylloxerised vines with sulphocarbonate of potassium applied with the distributing pail, in 1876-77, by M. Gueyraud.—Observations of the planet (175) Palisa, made at the Paris Observatory, with the west equatorial of the Garden, by MM. Paul and Prosper Henry.—Stellar systems of 36 Ophiuchus and 40 Eridan, by M. Flammarion.—General form of coefficients of certain developments, by M. André.—New mode of plane representation of classes of graduated surfaces, by M. Mannheim.—Experiments on the disruptive discharge made with the chloride of silver battery by MM. Warren de la Rue and H. W. Müller.—Rheostatic machine, by M. Planté. He combines a number of condensers (made of mica and tin), so as to be easily charged, from a secondary battery, in *quantity* and discharged in tension. The commutator is a long cylinder of hardened caoutchouc, having longitudinal metallic bands, and traversed by bent copper wire (for the two objects named). Metallic springs are connected with the two armatures of each condenser, and fixed on an ebonite plate on each side of the cylinder, which is rotated. A series of sparks can be got between the branches of the exciter in this arrangement, quite like those from electric machines with condensers. The discharges are always in the same direction, and the loss of force is less than in induction apparatus. A great many discharges can be had without the secondary battery being perceptibly weakened, as each discharge removes only a very small quantity of electricity.—On semi-diurnal barometric variations, by M. de Parville. The tropical hours may present, at a few days' interval, divergences amounting, during the great period, to forty-five minutes. The barometric variations in the tropical hours are not uniform; the maximum of descent of the mercury column occurs about three o'clock. Equality between the periods of day and night has never occurred. The amplitude of the variation is greater by day than by night, and during the dry season than during the wet.—On the action of anhydrous acids on anhydrous bases, by M. Bechamp. They are capable of uniting wholly.—On the determination of reducing sugar contained in commercial products, by M. Girard.—On the reducing sugar of commercial products in its relations to saccharimetry, by M. Morin. He shows the optical inactivity of this sugar.—On the production of racemic acid in the manufacture of tartaric acid, by M. Jungfleisch.—On some physical properties of *quercite*, by M. Prunier.—Action of solar light with variable degrees of intensity on the vine, by M. Macagno. Diminution of intensity hinders the production of glucose; the other elements (produced or assimilated) are in direct ratio of the luminous intensity. A portion only of potash is in inverse ratio of the luminous intensity: the contrary occurs in the case of potash combined with tartaric acid.—On the Orthonectida, a new class of animal parasites of Echinoderms and Turbellaria, by M. Giard.—On the calcareous algæ belonging to the group of verticillate Siphoneæ (Dasycladeæ, *Harv.*), and confounded with the Foraminiferæ, by M. Munier Chalmas.—Effects of faradisation in a case of hydrophobia in man, by M. Menesson. Considerable sedative effects were obtained; the patient, however, died after two days through a sudden stoppage of the heart's contractions.

BREHM'S THIERLEBEN

Die Säugethiere, von Dr. A. E. Brehm, 2 vols.; and *Die Insekten*, von Dr. E. Taschenberg, 1 vol. (Leipzig: Verlag des bibliographischen Instituts, 1877.)

THE three fine volumes of Natural History with the above titles form part of Brehm's well-known "Thierleben," a book which has had a well-merited success in Germany and on the Continent generally. The volumes on the mammalia, of which those under consideration are new and enlarged editions, and which contain the Quadrumana, Chiroptera, Carnivora, Insectivora, Rodentia, Edentata, Marsupialia, and Monotremes, had been well appreciated in this country on account of its excellent illustrations, trustworthy anecdotes, and general literary merits. The new edition issued in 1876 surpasses the old, for not only are the additional and new drawings of first class art and most truthful, but much of the context is more decidedly scientific than before. Brehm, with his practical knowledge of animals, especially of some important groups, and his literary powers and judicious choice of illustrative anecdote, was just the man to undertake a popular natural history; and the success of the very bulky attempt not only is greatly to his credit, but is a testimony of the love of good reading amongst the mass of his countrymen. A familiarly written introduction on the structure and physiology of the Mammalia occcupies the first chapter, and then the Primates are considered. There are two plates of sitting, standing, jumping, climbing, and swinging Anthropomorpha which are exquisite, and evidently carefully taken from the life. The rare Troglodytes Tschiego, the *Nschiego mbouvé* anatomised by Duvernay, is delineated in four attitudes, and the reach of the fingers below the knee is well shown; below it are three capital chimpanzees, but none of them equalling Wolf's admirable swinging chimpanzee in the possession of the Zoological Society of London. The orangs with their globular heads, projecting lips, and hirsute arms, are drawn with great force, and three gibbons, spidery and dangling, complete the show. A plate of hands and feet illustrates this part of the book, and the transition from the highest hand, probably that of *T. tschiego*, for it is more symmetrical than that of gorilla, to the lowest paw amongst the American marmosets is admirably shown. The dwindling of the thumb, the gradual equalisation in length of the three middle fingers, and the march first on the knuckles, and then, in the lower groups, on the palms are carefully demonstrated. Osteological anatomy is not much cared for, and therefore the skeleton of gorilla is not worthy of the book; but in the chapter on this great ape there are some very remarkable plates which enable us to approach the truth.

The chimpanzee comes next—and oh! there is such a sly-faced fellow in a woodcut, utterly beyond the capacity of any British cutter on wood—illustrating the genial species, after which, instead of before, as one would think ought to have been done, comes Du Chaillu's bald Troglodyte, the *T. tschiego*. With regard to this little-known beast, Brehm gives some more information about its size and general zoology, but he does not enlarge on the *Troglodytes aubryi* of Gratiolet and Alix. A group of Entellus monkeys, with their forehead tufts rather exaggerated, illustrates in part the few pages on the Semnopitheci, and the Macaci are finely delineated, a life-like savagery being given to the Rhesus and pig-tailed kinds. Brehm's anecdotes about the baboons are first-rate, and although the drawings of Hamadryas and the mandrill are slightly in exaggeration of what is common, they give a capital idea of the impudence of the one and the brutality of the other.

Brehm has collected all the good anecdotes and descriptions from Humboldt, Schomburgk, Rengger, and Hensel about the Howlers, and in spite of the silence of those in captivity in Europe we can imagine the terrific noise of a tree full of the adults of *Mycetes caraya*. Bartlett is fully and deservedly quoted in illustration of the natural history of the spider monkeys, and the delineations of the group are fairly done, ease of position being often wanting in the illustrations, however. The short-tailed Brachyures are for once described and drawn not in caricature; the context is mainly from Bates, and the sketch looks like a monkey and not like the distressed old man with a tail like an American vegetable marrow which is usually given in books. The Saimaris are introduced under the generic title Pithesciurus to which, and indeed to much of Brehm's zoological nomenclature, we demur. The marmosets are grouped, as by Huxley, as Arctopitheci, a name given to some sloths by Gray, and there is much confusion in introducing new generic terms to the genera Hapale and Midas. The use of the term Leopithecus for Hapale, of Hapale for Midas, for instance, shows the necessity for a final zoological arrangement of these small monkeys. No less than 239 pages are devoted to the apes and monkeys, and then the Lemuroida are commenced under the old-fashioned terms Hemipitheci or Prosimii. Sonnerat, Pollen, and Peters are Brehm's authorities for the natural history of this group, and he does not appear to have had the advantage of studying Mivart, Murie, Grandidier, and Owen; nevertheless the article is of good scientific value and of course the illustrations are superexcellent. There is, however, the old jumble of synonyms for the genus Indris, and Lichanotus and Propithecus are put in most unadvisedly. The queer Stenops, oddly named *gracilis*, Galago with his ears on the move and a bogie of *Tarsius spectrum*—if it were as big as a man how truly hobgoblin-like it would be—are excellent pictures. There is nothing new, however, about the group, and really more good information on anatomical and physiological subjects might have been given without detracting from the popular nature of the book. The Chiroptera are arranged in rather an old-fashioned manner, and are rather curtly treated; and then the second part of the volume opens with the Carnivora, to the exclusion of the Insectivora. The lion of course comes first, and although there is nothing to notice particularly in the context, every one must admire *Leo capensis* and the lioness of *Leo senegalensis*, although the specific determinations should sink into those of varieties. The sequence of species then becomes rather strange to English natural history, the puma and *Felis eyra* preceding "*Tigris regalis*" or *Felis tigris*. The clouded tiger comes next as "Neofelis," and the illustration is hardly that of the short-legged meek-looking creature in the Zoological Gardens. The jaguar, as drawn in the next page is too long in the neck, but the rounded top to the head is well given; the anecdotes and general history of this fine South American beast are beyond ordinary praise.

Brehm has paid unusual attention to the smaller cats, and the pages devoted to them are amongst the most interesting in the book, and when telling of the lynx, he gives a wood engraving by Beckmann of the common form which is wonderful in its details of face-expression and fur (p. 490). The Cheetahs, so interestingly numerous just now in our Zoological Gardens, are fully considered, and in the illustration there is the upward whisk of the tail given to perfection, but the muzzle of the beast is too long, and the fore legs hardly long and stilty enough. Cryptoprocta concludes the Felidæ, and *Canis primævus* of Cashmir commences a most interesting article on the dogs. Amongst other beauties there is "Der Bulldogg oder Boxer," and Mr. Bill Sykes would have been surprised to have learnt that it is called *Canis familiaris molossus gladiator*. It is "ein wuthendes, unzugangliches und stumpfsinniges Thier." Then there is its relation, *Mops*, with its sharply curled-up tail and black short nose, the tiny tongue tip not, however, being shown in the engraving, which tells the ladies of the period that Pug's real name is *Canis familiaris molossus fricator*. Amongst other dogs a sketch of a pointer by Beckmann is capital; he is pointing, and just a little in doubt, the tail dropping slightly and the head being not over-expectant. The first volume concludes with the natural history of *Otocyon* and *Canis procyonides*.

The second volume commences with a notice of the hyænas, and although there is not much to be said in praise of this contribution to their literature, still the delineations of *H. crocuta* and *H. brunnea* place the distinctions between the species plainly. *H. crocuta* is admirably drawn and the artist has managed to give it the peculiar weak look of the hind legs and drooping quarters of the caged animal. The Viverridæ are shortly treated, and one of the few doubtful drawings of the work is in illustration of *Cynogale bennettii*. The genus *Herpestes*, the habits of some of whose species have taxed the imagination of Europeans as well as that of Eastern races, follows; it is judiciously described and the anecdotes are good. The fur-yielding martens and their allies and other small carnivora valuable to the furrier are well illustrated, but Brehm had not the valuable volume on their natural history, lately issued by the American Survey, to learn from. The bears form a very interesting part of the book, but many of the illustrations have the positions of the animals rendered awkward by the attempt to give prominence to specific and peculiar structural points. Thus the polar bear in the water is wretchedly done, thanks to the endeavour to render the claws and narrowish snout very definitely comprehensible. The moles and hedgehogs are fairly noticed, but want of space begins to affect the treatment of these lower groups, but Galeopithecus, very shortly described, is properly placed at the head of the Insectivora. The Rodentia are of course full of anecdote and light literature, but Brehm's illustrations are by no means as good as those of the other groups; perhaps the most striking is that of *Cercolabes prehensilis*. A capital plate of the sloth shows the short snout which almost looks moist, and for once in a way amongst books of this kind, there is a truthful rendering of the long narrow wrist with its two claws. The essay on the sloths and ant-eaters is admirable, but the anxiety to show the peculiar progression of the last group, on the anterior extremities and the position of the claws, has often led the artist to exaggerate. The Marsupials are well illustrated and with great ability, but we miss some of Gould's most life-like sketches so familiar in most popular works. The pages devoted to the Monotremes contain the usual stories, and unfortunately were written before those important additions to their natural history were published, and which have lately been noticed in NATURE.

The other volume (the ninth of the work) before us is by Taschenberg, of Halle, and is a second edition of the part containing the Insecta, Myriopoda, and Arachnida. The species representing groups are of course well chosen as types, and the author has often taken pains to place novelties before the reader, especially in the way of illustration. The short anatomical introduction is sufficient for the general reader, but barely so for the young student. Amongst unusual forms, or rather unusual to the common routine of book making, is *Mormolyce phyllodes*, from the upper hill country of Java, with its wide leaf-looking elytra and long antennæ, and the very common and opposite-looking *Scarites pyracmon*. The burying propensities of Necrophorus are told and illustrated, and there is a very curious and striking plate of a mole hanging by the neck in a trap, with a crowd of Silphidæ (shield beetles) and larvæ, besides blow-flies, on and about it, doing their best to turn its protoplasm into theirs. Some pests to museum-keepers and housekeepers are especially figured in the act of working away at a hare's foot which rests on pen, ink, and paper *Anthrenus musæorum* larva and adult, *Attagenus pellio* and *Dermestes lardarius* are there in full enjoyment of their mischievous propensities. The natural history of Lampyris, Meloe, and Sitaris, is cut too short, doubtless for want of space, but their interesting life cycles merit more attention than that of many others which are barely more than mentioned by name and might be left out. *Apoderus longicollis*, a Javanese species looking like a cameleopard amongst beetles, and unfortunately little known, has an interesting engraving; and equally good is that of the langkafer Brenthus. Amongst the Hymenoptera the habits and nests of *Bombus terrestris*, of *Odynerus parietum*, and of the curious Belonogaster and the Sandwasp are very well explained and drawn; and great praise must be given to the delineations of the life cycle of Othalia and Cimbex.

The only fault to be found in the treatment of the Lepidoptera is that the article is too short, but the illustrations are very good. A plate of a rush of a myriad of the maggots of *Sciara militaris* is a strange subject, but very effective, and the long crowd of closely-packed dark-headed long things looks as if short work was to be made of carrion. Amongst the leaf insects there is *Mantis religiosa* preying rather than praying with a fly in its clasp, and a host of larvæ escaping from a mass of eggs; and there is an equally interesting cut of *Bacillus Rossii*, one of the Phasmodea. A short chapter on the unsavoury subject of Pediculi precedes a sketch of the Cochineal insects, and then, after noticing the Chermes that attacks that very strong food the larch, we come to a full description of *Phylloxera vastatrix*. The Hemiptera are shortly mentioned, and then the Myriopoda. There is a good picture of Geophilus clinging around its great prey, a large earthworm, and also of a Polydesmus. Amongst the Scorpions the long-armed Phrynus and Gonoleptes, and amongst the Spiders a long Tetragnatha and the extraordinary-bellied Gasteracantha, form admirable illustrations. A short chapter on Pycnogonum and Nymphon concludes this really wonderful volume. P. M. D.

OUR BOOK SHELF

Heat. By B. Loewy (Lardner's Handbook of Natural Philosophy. Crosby Lockwood and Co., 1877.)

THIS, though not a bulky book, is a sort of miniature Encyclopædia of the subject. So far as we have read it it seems to have all the faults of the original (?) work to which Lardner's name was prefixed, with the important exception of the inaccuracies. These have been to a great extent removed, and the work has been brought up to date, but there is still the woeful want of order, or indeed of any guiding principle whatever which distinguished the former editions. It is a very curious mixture of good and bad, and cannot be called, in any sense, attractive to the reader. Numerous tables of experimental data are given, but they are in many cases carried to a number of places of figures quite beyond the present power of experimental science. Two, or perhaps three of the figures in the earlier places of each number are probably correct; the others give a show of minute accuracy which may altogether deceive the beginner. The treatment of the theoretical part is very meagre, but in the experimental part many curious facts not usually known are given. The book may be useful as a work of reference to those who are not in possession of Balfour Stewart's treatise, but we cannot say more in its favour.

Ferns, British and Foreign. The History, Organography, Classification, and Enumeration of the Species of Garden Ferns, with a Treatise on their Cultivation. By John Smith, A.L.S., Ex-Curator of the Royal Gardens, Kew. New and Enlarged Edition. (London: Hardwicke and Bogue, 1877.)

THAT Mr. Smith's "Ferns, British and Foreign" should have reached a new edition in a comparatively short time is no small tribute to its value as a book of reference for amateurs and fern cultivators. The chief portion of this very neatly got up work is occupied by an enumeration of cultivated ferns. The different genera, as understood by the author, who was one of the foremost pteridologists of his day, are described and figured, while a list of the cultivated forms, with synonyms and range of geographical distribution, follow under each genus, no attempt being made to give a diagnosis of the species. The scope of the work is therefore entirely different from that of the "Synopsis Filicum" of Hooker and Baker. The classification adopted is that propounded by Mr. Smith in his early publication on ferns, an arrangement not much used by modern writers. An appendix of recently-introduced ferns is given. These have been collected and arranged under their respective genera and tribes, as their names have from time to time been noticed in the horticultural journals and in nurserymen's catalogues. The list has thus no pretensions to be a critical one. The most interesting part of the book is the history of the introduction of exotic ferns, a subject about which, probably, no man living knows more than Mr. Smith. This is followed by an explanation of terms used in describing ferns, perhaps the least satisfactory part of the whole volume, as many of the terms are more or less obsolete, or only used in the book now before us. In this section nothing is said about the recent researches into the nature of the prothallus, construction of the reproductive organs, and morphological nature of the sporangia. The last part of the work is occupied by an essay on the cultivation of ferns, reprinted without alteration from the first edition, but giving the results of long experience of the successful cultivation of all groups of ferns. As a work of reference and guide to the cultivation, this book will most undoubtedly be of great service to the fern-growing public.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.]

The Radiometer and its Lessons

I HAVE little doubt that Prof. Osborne Reynolds is much more competent than I am to say what is or is not consistent with the kinetic theory of gases, but I hardly think that he gives evidence of this in his letter to last week's NATURE (p. 27). Unless my ignorance of the matter is more complete than I am aware of, the law that the rate of communication of heat to a gas is independent of the density, applies only when the space occupied by the gas is so great, or the variations of density so small, that these variations do not alter the temperatures of those portions of the gas which are at each instant respectively receiving and giving out heat. This condition cannot, I imagine, be fulfilled in the radiometer, where it seems to me inevitable that an action of the kind to which Mr. Johnstone Stoney called attention must take place. G. CAREY FOSTER

P.S.—Since writing my previous letter to NATURE, a fortnight ago, I have read a paper by Mr. R. Finkener, in *Poggendorff's Annalen* (vol. clviii. pp. 572–585). This paper contains, besides a theoretical investigation of the motion of the radiometer founded on the kinetic theory of gases, an experimental proof that the action becomes much less when an extremely high degree of rarefaction is reached. The paper itself is not dated, but, as the Part of the *Annalen* which contains it was "closed" on July 31, 1876, the experiments described in it cannot have been much, if at all, subsequent to those (communicated to the Royal Society, June 13, 1876) which led Mr. Crookes to a like result. G. C. F.

UNTIL I read Dr. Carpenter's letter in your issue of the 8th inst., it had never occurred to me that his "special purpose" was to bring out strongly my "thoroughly scientific and philosophical method!" This is an act of disinterested kindness which recalls to me the exquisite truth of Dean Swift's remark, "No enemy can match a friend'

Dr Carpenter's only reply to my letter which appeared in your issue of the 1st inst. is contained in the following passage:—"If I had not found," he says, "after the publication of my Lectures, that he had himself been 'digging up the hatchet,' which I was quite disposed to keep buried, by giving his public attestation to the 'spiritualistic' genuineness of what had been proved to be a most barefaced imposture, I should not have again brought his name into the controversy."

Further on Dr. Carpenter paraphrases passages from his article in *Fraser's Magazine* for this month, in which he goes more into detail touching this "public attestation," of which in his eyes I stand accused.

"Eva Fay," he says, "returned to the United States, carrying with her a letter from Mr. Crookes, which set forth that since doubts had been thrown on the Spiritualistic nature of her 'manifestations,' and since he in common with other Fellows of the Royal Society had satisfied himself of their genuineness by 'scientific tests,' he willingly gave her the benefit of his attestation. This letter was published in *facsimile* in American newspapers."

My answer to this calumny shall be brief.

It is untrue that I dug up the hatchet—Dr. Carpenter's expression—in the interval between November 30, 1875, when he proposed it should be buried, and the time of his first subsequent attack upon me.

It is untrue that during this interval, or at any other time, I gave my "public attestation to the spiritualistic genuineness of what had been proved to be a most barefaced imposture."

It is untrue that I gave Eva Fay a letter, speaking of the "Spiritualistic nature of her manifestations," and referring to "Fellows of the Royal Society."

It is untrue that Eva Fay "returned to the United States carrying with her" such a letter.

It is untrue that "this letter was published in *facsimile* in American newspapers."

When Dr. Carpenter limits himself to definite statements, my task is not difficult. It is, however, less easy to answer a *rumour* of *something* which *somebody* told Dr. Carpenter I *privately* admitted.

"It has been rumoured," says Dr. Carpenter, in *Fraser's Magazine*, "that Mr. Crookes has *privately* admitted that some of his 'mediums,' when they could not evoke the 'manifestations' by *fair* means, have done so by *foul*."

I admit that such a rumour respecting Eva Fay was circulated in the United States, and a Boston gentleman wrote and asked me if there was any truth in this statement. I replied as follows under date November 8, 1875:—

"In reply to your favour of October 25, which I have received this morning, I beg to state that *no one* has any authority from me to state that I have any doubts of Mrs. Fay's mediumship. The published accounts of the test *séances* which took place at my house are the best evidence which I can give of my belief in Mrs. Fay's powers. I should be sorry to find that any such rumours as you mention should injure Mrs. Fay, whom I always found most ready to submit to any conditions I thought fit to propose."

Considering that this was a private letter from one gentleman to another, written *currente calamo* without any thought of subsequent publication, few of your readers, I believe, will see much harm in it. Not being aware that private communications were less sacred in America than in England, I was certainly surprised one morning to receive a copy of an American newspaper containing a *facsimile* of this private letter.

It will be observed that this letter is dated November 8, 1875, whereas the "bury-the-hatchet" episode took place on November 30, 1875; this therefore cannot be the letter which convicts me of attesting to a "barefaced imposture" subsequent to November 30.

Moreover, this letter does not contain the words "Spiritualistic nature of her manifestations." Neither does it allude to "Fellows of the Royal Society." Nor did Eva Fay return to "the United States, carrying with her this letter." Nor was it even addressed to Eva Fay. It is then impossible that this can be the letter to which Dr. Carpenter refers, and I demand that he prove the truth of his allegation by producing a copy of the "American newspapers" containing a *facsimile* of a letter written by me answering his description, containing the words which he professes to quote from it, and justifying his defamatory remarks.

In your issue of last week (p. 26) Dr. Carpenter says nothing about this *facsimile* letter, but lays stress on an article written by me ten months previously. Does he seriously mean that the publication in March, 1875, of an account of some test experiments is a breach on my part of his "bury-the-hatchet" offer made the following November?

I have evidently been labouring under a misapprehension as to what Dr. Carpenter meant when he proposed to "bury the hatchet." I supposed he intended to cease misrepresenting my views and falsifying my experiments at his public lectures, and never afterwards to repeat such calumnies on my scientific position as he had anonymously contributed to the *Quarterly Review* for October, 1871. It seems, however, that Dr. Carpenter really meant that I was no longer to go poaching on his own special preserve, and was to abstain for the rest of my life from writing even a private letter on a subject which he has investigated for more than thirty years, and about which he is now writing and lecturing with redoubled vigour.

Dr. Carpenter refers to an offer made in May, 1875, "by Eva Fay's manager, that for an adequate sum of money the 'medium' should expose the whole affair," and he vouches for its truth by saying he has seen "copies of the letters." I can supply, not *copies*, but *original* letters. I have before me letters from Eva Fay, dated Birmingham, May, 1875, speaking bitterly of the temptations and persecution to which she was being subjected to induce her to join in the scheme, to which she was no party.

But how, may I ask, does an abortive conspiracy to complicate "*six big guns*" prove that my "scientific tests"—which with all deference to Dr. Carpenter's "good authority" can *not* be evaded by a "dodge"—were useless, and that in spite of them Eva Fay cheated me?

I am weary of protesting against the imputation which Dr. Carpenter conveys in the words "scientific advocates of the system." I emphatically deny that I have ever advocated any "system" in connection with the phenomena ascribed to spiritualism. I have never for one moment doubted that this name has covered an enormous mass of fraud and trickery; but being convinced that amidst all this falsehood—which it is Dr. Carpenter's mission to denounce in the most fervid eloquence at command—there was a solid nucleus of fact, and believing that every unrecognised fact is a reproach to science, and every uninvestigated phenomenon is a probable mine of discovery, I considered myself not merely entitled, but almost bound in scientific honour, to attempt the solution of the question. My attempt to bring the so-called supernatural within the realm of fact, to turn the light of science on a problem that required investigation, has exposed me to many misrepresentations, but especially to the ire of Dr. Carpenter, who never tires of repeating every idle tale from hearsay evidence. I look back to the days of the alchemists, and find the very same kind of fraud, mysticism, and trickery, differing but little from the impostures of the present day. But then, as now, there were a few earnest students who detected the germs of truth amidst the ravings and juggleries of the gold makers; they cherished these germs, and although the Dr. Carpenter of that period would doubtless have denounced those students as "scientific advocates of the system" of alchemy, and felt it his duty to "undermine" their reputations, they persevered through calumny and ridicule, and thereby laid the foundations of our modern science of chemistry.

The readers of NATURE have now before them ample illustration of the falsity of the accusations with which I have been persecuted for so many years. A calumny once born, said the Great Napoleon, can never be killed. I have, however, done my utmost to prove the groundlessness of the very serious charges Dr. Carpenter has brought against me, down to the grave indictments in your issue of last week (p. 26). There is not a single charge which Dr. Carpenter has ever brought against me that I am unable to answer with like completeness; and, judging from long experience, I venture to say that any future charges he may bring will be equally unfounded. But I cannot, out of regard for your readers, to say nothing of the sacrifice of time, continue to defend myself from every petty accusation; and unless really forced by some imputation too serious to pass over, this must be my last letter on a subject which to me involves painfully too much self-reference. I have been constrained, in self-defence, to speak in somewhat downright fashion, but Dr. Carpenter's industrious misconstruction has drawn this protest from me. Misstatements expressed in a few lines may require pages to refute them. A calumny which takes a minute to write may demand days to answer. Memories of half-forgotten occurrences have to be revived, conversations recalled, old letters hunted out, journals exhumed, and, in fact, as much time and trouble expended as if getting up evidence for an important legal trial. So great a tax for so trivial a purpose is monstrous in its disproportion, and I can waste on this fruitless discussion no more precious time—time stolen from my physical work in the laboratory, already too much curtailed by the pressure of outward business.

November 10 WILLIAM CROOKES

THE latter half of Dr. Carpenter's letter in last week's NATURE (p. 26) consists of almost verbatim extracts from his article in this month's *Fraser*. I beg to refer your readers to a reply to Dr. Carpenter's attack, and a full exposure of his false accusations against Mr. Crookes and myself, which will appear in the next issue of that magazine. They will then see *who* has been led by "prepossession" to adopt "methods which are thoroughly *un*scientific," and *whose* are "the statements which ought to be rejected as completely untrustworthy."

ALFRED R. WALLACE

Experiment on Fluid Films

I AM experimenting on the optical phenomena exhibited by thin fluid films in a state of vibration, and have just obtained some beautiful results, including the formation of fixed straight and curved coloured bands, arranged in symmetrical figures, and of pairs of colour-vortices rotating in opposite directions.

Unless these results prove to have been already described, I shall shortly publish an account of my experiments.

SEDLEY TAYLOR

Trinity College, Cambridge, November 12

Expected High Tides

IN your "Notes" last week you say that you cannot understand why the burden of such predictions should fall solely upon Capt. Saxby. This is what many of the public also do not understand. Why does not, say, the Meteorological Office take the matter in hand, and not leave it to some private individual? There can be no doubt the forewarnings are often of the greatest service and have saved the public tens of thousands of pounds and prevented a great deal of misery. What I think Capt. Saxby is to be blamed for is the desire—it may be only apparent—to make a mystery of his predictions with the general public; and what gives weight to this is the fact that the Astronomer-Royal and the heads of the Meteorological Office and Society do not offer the public any aid in what is a purely scientific and eminently practical subject, in which Londoners are more interested than in the transit of Venus, and quite as much as in the storm-warnings for the Channel.

When in March, 1874, Capt. Saxby came forward and in an oracular way predicted a great tide on the 20th, he gave no reasons. This many felt was unsatisfactory. Knowing that it must result from the action of natural laws curiosity led me to investigate the matter, and I found that the subject of extraordinary tides was a matter of much simplicity; that the chief factors reside in the moon with its varying distances and declinations; the next in the sun and the seasons; the next in the winds and atmosphere; and the next, perhaps, in the action of the planets, as Venus and Jupiter, the former of which we know affects the orbit of the earth, and both have probably some power in producing the atmospheric disturbances in the sun.

With these factors I predicted a year in advance the extraordinary tide of November, 1875, which had escaped Capt. Saxby's notice. I was also able to say that there are two unusually high tides revolving through the year, exactly six-and-a-half synodic months apart, each forty-eight days after the same tide of the previous year; that these with the preceding and succeeding tides are chiefly those which may with bad weather develop into extraordinary ones; and that the next great one—a very giant among tides—will be on March 20, 1878.

If Capt. Saxby has some knowledge on the subject which others have not, how is it he did not predict the unusually high tide of October 26 last, which happened when the moon was neither full nor new, nor in perigee? Why it happened is somewhat of a mystery; the only explanation I can suggest is, that the moon had her highest northern declination on that day, and that a barometric depression passed over the North Sea the previous day, both which would tend to heighten the tide.

The Towering of Wounded Birds

LAST season I fired at a song thrush at a distance of fifty yards, but the bird continued its course, as if uninjured, for upwards of 200 yards, when it suddenly "towered" in the air, and as suddenly fell to the ground. Upon examination the bird was found to have been shot through the lungs alone, and had bled internally, the throat being full of clotted blood. The head was totally free from any injury. I have known similar instances occur in the pigeon, swallow, and starling. In all these cases the head remained uninjured, and death occurred through internal hæmorrhage. In the case of the starling one pellet entered the spine; the bird continued its course for a few yards, towered, and suddenly fell to the ground dead.

Should you consider these instances bearing on the matter of sufficient importance for an insertion in NATURE they may prove acceptable to those who are interested in the subject.

Heeley, near Sheffield CHARLES DIXON

Cruelty to Animals' Act and Physiological Teaching

I AM desirous of knowing through your many readers if, amongst physiologists, the belief is anything like general, that showing under the microscope the circulation of the blood in a web of a frog's foot is a contravention of "The Cruelty to Animals' Act, 1876."

Dr. M. Foster, in his "Primer of Physiology" (Macmillan and Co., 1877), advises the reader to "go and look at it at once; you will never know any physiology till you do;" and some naturalists here say if no incision is made, the animal being merely tied down, the exhibition of the phenomenon is quite legitimate, while, on the other hand, Prof. Huxley, in his paper before the Domestic Economy Congress (reported in NATURE, vol. xvi. p. 234) states it as his opinion that a teacher is "open to the penalty of fine and imprisonment if he *uses*" a frog "for the purpose of exhibiting one of the most beautiful and instructive of physiological spectacles."

It was this, the expressed opinion of so distinguished an authority as Prof. Huxley, which caused me first to doubt the teacher's right to exhibit the experiment, and it is because of the differences of opinion I have mentioned that I seek to know through your columns, if a teacher is or is not at liberty to illustrate the blood circulation by this harmless experiment.

FRANK W. YOUNG

High School, Dundee, November 12

Smell and Hearing in Moths

NUMBERS of moths, of many different species, are attracted into my room on summer evenings by the light; and they are fond of resting on the lamp shade. One night I was using some very strong ammonia solution—and by way of driving them off I held a 3-ounce bottle of it with the open mouth almost close to them. To my surprise they seemed quite unconscious of it *as a smell*; they would bear it unmoved for a minute, or sometimes for two or three minutes, and they then merely walked an inch or two further away from it. I have since tried the experiment repeatedly, and with several different species; but none of them seem to detect the presence of ammonia except as a man might detect the presence of carbonic acid or of nitrogen in excess, that is, by their effects on his system generally.

The common black and white "magpie moth," it is well known, often feigns death when captured. I caught two, one after the other; both pretended to be dead, and I laid them gently on the table a few inches apart. They had remained motionless for ten minutes, when I took up a wine glass by the stem, and gave it one sharp stroke with a pencil, about six inches away from them. Both moths flew off at the instant the sound was heard. I repeated this many times with the same result—both with these and with other individuals of the same species; and I also found that merely holding the glass near them and waving the pencil about noiselessly, did not arouse them.

Loughton J. C.

Bees Killed by Tritoma

IN a friend's garden here where there are quantities of Tritomas or "red-hot-pokers," hundreds of bees have been this year destroyed by them. The honey produced by the flower is very abundant, and the bees enter the tube of the corolla to get at it; but the tube, which is only just large enough at the mouth, tapers gradually, and so the bee gets wedged in and cannot extricate itself. I saw numbers so caught, some in the fresh flower, while others remained in the completely withered and decaying blossoms. Perhaps it may be due to the fine warm days we have had this autumn, inducing the bees to work too late after our native honey-producing flowers have been destroyed by the wet and frosts; or is it a regular thing which happens every year? If so bee-keepers should discourage the Tritoma, or set to work to select varieties with flowers large enough not to kill their bees.

ALFRED R. WALLACE

Dorking, November 3

Lecture Experiment

THE experiment described below illustrates in a very striking manner the particular instance of the "conservation of energy" exhibited by the equilibrium of liquids of unequal densities, in communicating vessels.

The apparatus consists of a two-necked bottle, having in one neck a very strong glass tube half a metre, or more, in length, and terminating above in a funnel of 200 c.c. capacity, while its lower end nearly reaches the bottom of the bottle; in the other neck is a piece of glass tube, drawn to a jet, and passing only a short distance into the bottle. As the pressure inside the apparatus is considerable, the corks by which these tubes are fixed must fit very tightly.

In using the arrangement the bottle is filled with water, the jet is then closed with the finger, and the funnel, which should be supported on the ring of a retort stand, is filled with mercury; on removing the finger from the jet the mercury falls into the bottle, expelling the water which rises in a fountain to a height depending upon that of the column of mercury, but rather less than is theoretically possible, the height of the fountain being ten or eleven times that of the fall of mercury. By employing mercury as the falling liquid in Hero's fountain a similar increase of effect may be obtained with that apparatus.

W. A. SHENSTONE

Fownes' "Manual of Chemistry"

IN my review of Fownes' "Manual of Chemistry" are two mistakes which I beg to correct. On page 25, line 1, read *improbable* instead of improvable; and line 6, *dimorphides* instead of isomorphides.

THE REVIEWER

OUR ASTRONOMICAL COLUMN

THE TRANSIT OF MERCURY, MAY 6, 1878.—The transit of Mercury, which will occur on May 6 in the ensuing year, is the last during the present century in which the planet can be observed upon the sun's disc for any length of time in this country, and on that occasion the nearest approach of centres will take place only half an hour before sunset; owing, however, to the long duration of the transit, 7h. 35m. geocentric, Mercury will have been upon the disc more than four hours and a quarter when the sun sets. Reducing to Greenwich by the *Nautical Almanac* data it appears the first external contact will occur at 3h. 10m. 58s. mean time, and the first internal contact at 3h. 14m. 4s., or the planet will be 3m. 6s. in wholly entering upon the disc. The least distance of centres will occur at 7h. 0m., and sun-set at 7h. 29m. The duration of the transit is longer than in any other of this century, or indeed than in any one that has occurred since the year 1756.

Up to the present year twenty-four transits of Mercury have been more or less observed; in this number are included that of 1631, November 7, predicted by Kepler, when the planet was seen upon the sun's disc for the first time by Gassendi, at Paris, who observed on the dark-chamber method—by allowing the sun's light to pass into the room through a small aperture in the window, and throwing his image upon a white screen; that of 1651, November 3, imperfectly seen by Shakerley at Surat, and that of 1707, May 6, which was observed through clouds by Roemer at Copenhagen near the egress. Of these *twenty-four* transits it is singular that only *eight* have taken place at the descending node or in May, as will be the case next year. Two-thirds of the number have therefore occurred in November, when we might have expected the hindrances to observation to have operated unfavourably in these latitudes.

Of the three transits of the present century subsequent to 1878, that of 1881, November 7, will be wholly invisible in this country, the ingress taking place at 10h. 16m. and the egress at 15h. 37m.; in the transit of 1891, May 10, the egress occurs soon after sun-rise; and in that of 1894, November 10, it occurs near sun-set. The reader who is curious respecting the transits of Mercury in the next century may consult a communication from the Rev. S. J. Johnson to the Royal Astronomical Society in the *Monthly Notices*, vol. xxxvii. p. 425; and for an account of Gassendi's long watch for the transit of 1631, and his successful observation of it, he may be referred to Prof. Grant's classical work, the "History of Physical Astronomy."

NOVA CYGNI, 1876.—Prof. Julius Schmidt mentions that the star which he first remarked on Novemb[illegible], 1876 (and which is not found in the *Durchmusterung*) diminished very regularly from January to August of the present year; it exhibited none of the slight oscillations in brightness which are still seen in T Coronæ, and we may add in other "Novæ." With the Athens refractor he has observed three small stars near the variable, with the following differences of right ascension and declination:—

					s.			
13m	...	y =	Nova	−	1·0	...	Nova	− 45″
13	...	z =	,,	−	1·6	...	,,	− 81
12·5	...	x =	,,	+	4·6	...	,,	+ 20

It will be remembered that this star suddenly shone out of 3·4 magnitude, and had diminished to the limit of naked-eye vision soon after the middle of December. Its mean place for 1880·0 is in R.A. 21h. 36m. 59·9s., N.P.D. 47° 42′ 16″.

COMET 1873, IV.—M. Raoul Gautier has worked out definitive elements of the comet discovered by M. Borrelly on August 20, 1873, and finds the observations best represented by an ellipse with a period of 3,277½ years, the probable errors of perihelion distance and eccentricity limiting the period between 3,012 and 3,585 years. This comet, however, was observed for one month only, or through an orbital arc of only 58°, and such results of calculation in the present case are not perhaps to be allowed any great weight. There are many other comets which we imagine would better have repaid the labour expended by M. Gautier upon Comet 1873, IV. Expressing his best *parabolic* elements in the manner adopted in catalogues of comet-orbits, we have the following figures:—

Perihelion Passage, 1873, September 10 83679 M.T. at Berlin.

		°	′	″	
Longitude of perihelion	... ...	36	48	40	M.Eq 1873 0
,,	ascending node . .	230	38	4	
,,	inclination	84	0	50	
Log. perihelion distance	... ...	9 899956			

Motion—retrograde.

MINOR PLANETS.—A remark in this column some time since upon the probability of several discoveries of so-called new planets proving to be observations of bodies previously detected, appears to be justified by recent experience. Thus the object announced as a new planet by Prof. Watson and M. Borrelly in August last was shown by Herr Knorre, of Berlin, to be identical with No. 141, detected by M. Paul Henry at Paris, on January 13, 1875, and it is now stated that the small planet remarked by Herr Palisa at Pola on October 2 is really No. 161, which was discovered by Prof. Watson on April 18, 1876, and received the name *Athor*. As was to be expected from the rapidity with which discoveries of small planets have succeeded one another of late years, calculation is now considerably behind observation, and we are still without published elements of a number of the bodies lately brought to light.—Prof. Peters states that he has proposed the name *Iduna* for the planet discovered by him on October 14, which is No. 175, a name which he says will be understood by those members of the "Astronomische Gesellschaft" who, at their late meeting at Stockholm, participated in the hospitality of "Ydun."—There is now a strange confusion of mythologies and systems of nomenclature in the minor-planet group, a state of things that at one time might have been readily avoided.

THE ROYAL DUBLIN SOCIETY

A SCHEME for the reorganisation of this society as a branch of the National Museum of Science and Art established by the Government has been under consideration for some time, and a report of the council on the subject was submitted to the society at its meeting on November 8. The scheme includes a recommendation in favour of the amalgamation of the agricultural department of the society and the Royal Agricultural Society, under the title of the Royal Irish Agricultural Society; after some discussion the report was carried. The following are the principal points involved in the reorganisation:—

In accordance with the agreement entered into with the Government, the principal conditions of which are embodied in the "Act for the Establishment in Dublin of a Science and Art Museum and the Development of the Library of the Royal Dublin Society into a National Library," the property of the society in land, buildings, and collections has passed into the possession of the Government. The society will, in accordance with such agreement, receive the sum of 10,000*l.*, which will be invested in such security as, subject to the approval of the Treasury, may be selected; it will continue to be provided with the requisite accommodation in Leinster House; the members will have free access to the several departments as heretofore, whilst the existing members, as well as all those who shall be admitted before January 1 next, will have the right to borrow books from the National Library. In order to assist in the more complete development of that part of the society's work which is devoted to the promotion of science and the useful arts, it has been arranged that all the scientific serials and transactions of learned societies, as well as all duplicates in the library, shall remain the property of the society; the Lecture Hall and Laboratory will be reserved for its use; and the collections in the Botanic Garden and Museum of Natural History will be available as formerly for the illustration of papers read before the society. The most important condition, however, for the successful prosecution of the society's scientific work, pure as well as applied, is that for five years the cost of printing the scientific papers read before the society will be defrayed by the Government. Concessions equally favourable have been obtained for the agricultural department. Thus in lieu of the premises around Leinster House, which will be required for museum buildings, &c., the Government has undertaken to provide accommodation for agricultural shows elsewhere, and to reimburse the society for any pecuniary loss it may sustain in consequence of the change of site from the city to the suburbs. In order to develop the scientific work of the society, and thus secure to the fullest extent the great advantage of having the scientific papers read before it, printed, the Committee of Science have submitted a scheme for the complete reorganisation of the department under their superintendence. Thus, the meetings for the discussion of subjects connected with science pure and applied will be held in these sections:—1. For the physical and experimental sciences. 2. For the natural science, including geology and physical geography. 3. Science applied to the useful arts and industries. The papers to be read at these sectional meetings will be published in 8vo, as the Scientific Proceedings, the more important to be published in 4to, under the title of "Transactions." In order to consolidate and economise both work and time other scientific bodies have been invited to associate themselves with the work of the sections, the meetings of which will be held simultaneously on the third Monday of each month, an invitation to which the Royal Geological Society and the Scientific Club have responded. A special committee is now engaged in considering the measures most advisable to adopt with regard to the future of the society, so as to maintain it as an object of attraction to the educated classes, and a preliminary report has been presented to the council, in which it is advised that in addition to the more complete organisation of the scientific department steps should be taken to render the reading-rooms more efficient, to establish a lending library for the use of future as well as present members, to arrange for the delivery of lectures for the elucidation of the latest discoveries in science, and to hold occasional *conversaziones*. According to one of the conditions contained in Lord Sandon's letter of February 9, 1876, the National Library will be placed under the superintendence of a council of twelve trustees, eight of whom are to be nominated by the Royal Dublin Society and four by the Government.

Then followed the Report of the Committees of the Royal Dublin Society and of the Royal Agricultural Society on the subject of amalgamation, which, as we have said, was adopted. The two societies will to some extent remain connected; the Agricultural Society, Lord Powerscourt stated, would be a branch of the Royal Society, though under different management.

ON THE EOCENE FLORA OF BOURNEMOUTH

DURING this last summer and autumn I have seized several opportunities of continuing my examination of the Bagshot Beds of Hampshire and the Isle of Wight, some of the results of which I think may interest your readers. This series is, as is now well known, of great importance from the fact of its being almost the only series from the tertiaries whose absolute relative geological age is positively known, it being under and overlapped on the mainland by the London clay and Bracklesham beds respectively, whilst in the Isle of Wight, occurring in a complete series of eocene strata, upheaved vertically, its true position is even still more plainly seen. It is further important as exhibiting in gradual sequence the change from an upland to a swamp flora, and represents very fairly the local flora of a long period and of an entire continent that has passed away. Of the richness and completeness of the flora an idea may be formed from the fact that I can reckon in my own collection not less than 10,000 selected specimens, many of large size, exclusive of twice that number which I have discarded, whilst there are also local collections at Bournemouth, a splendid series in the Cambridge Museum, and a scarcely less important one from Alum Bay, at the British Museum. But perhaps the most valuable discovery—to the botanist, at all events—is that of various beds containing well-preserved fruits above the horizon of the leaf-patches, identifiable with fruits from Sheppey which are found in the London clay, and therefore below the leaves. We thus appear to have at Bournemouth the leaves of trees which may be descended from those whose fruits are imbedded at Sheppey. The assistance, it will be readily seen, of the Sheppey fruits will be of the greatest value in determining the genera of the Bournemouth leaves and flowers. At Bournemouth about sixteen kinds of fruit may be collected in the seed-beds just mentioned, including Nipadites, Hightea, Cucumites, and Petrophiloides, quite sufficient to establish the fact that no break took place in the succession of the London clay flora.

The number of forms also common to Bovey Tracey is worthy of note. The most abundant fern at either locality is *Pecopteris lignitum* (now believed to be an Osmunda). *Palmacites dæmonorops* of Heer, from Bovey, is no other than the Cactus of which I have frequently made mention. The dicotyledons of Bovey ascribed to Laurus, Ficus, Daphnogene, Dryandroides, &c., appear also to be identical with those of the Bagshots, and it is therefore not at all improbable that the miocene age of the Bovey Tracey beds, determined, as it seems to me, on most slender grounds, will have to be reconsidered.

The extremely local distribution of the leaves in patches, each with its distinguishing group of plants, has again in fresh instances come prominently under my notice. At Studland, in one bed, fan palms with a three-foot radius lie massed together, but in a decomposed state; and I only succeeded by using the utmost care in extracting one specimen showing the full length of the leaf. At

Bournemouth a small bed of dark clay was found full of leaves of feather palm, crossing each other in every direction; the tip of a frond in my collection measures four feet in length, by three feet broad. Amongst other interesting specimens is a Smilax leaf of larger dimensions than any now living, and a twig of Dryandra, with many leaves attached, from Alum Bay, which unites in itself several of M. Watelet's species from the Grès du Soissonnais. The discovery of a finely preserved neuropterous wing, and of two apparently hemipterous abdomens, are of interest in connection with the large series of insect remains from Garnet Bay, Isle of Wight, lately deposited in the British Museum.

The history remains to be written of the subsidence of the great continent, whose further limits Edward Forbes surmised are yet traceable in the banks of Gulf Weed, ranging between the 15th and 45th parallels. Many, however, have written on Atlantis, but lacking the direct proof of its former existence in comparatively recent times, which has since come to light. The disappearance of almost an entire continent, is not a more startling proposition than the elevation of the Alps, Pyrenees, Apennines, and Carpathians, over whose highest summits the sea rolled at this period. Of the history of this disappearance Bournemouth presents us with but a page, still a page full of meaning. The incoming and disappearance in succession of oaks and beeches, figs and laurels, palms and delicate ferns, the swamp-loving aroids and Eucalyptus, Chrysodeum and Osmunda, on the same spot; the appearance in masses of the fruit of Nipa, which is stated by travellers to be found in brackish estuaries; the incoming of shore crabs and mud-boring crustacea, sea-shells and Flustra, shingle beeches and deeper sea deposits, are each well-marked stages in the history of the disappearance of this continent, whose existence at this and a later period may be gathered from the writings, made from different standpoints, of Prestwich, Godwin-Austen, Sorby, and many others. The Bournemouth and Sheppey vegetable remains were brought down by one of the rivers draining this continent, which at a later period silted over the reptiles of Hordwell and the estuarine shells of the fluvio-marine series. That the oscillations which gradually led to the disappearance of the land, vestiges of which remain in Cornwall, the Channel Isles, Brittany, Madeira, &c., have not ceased, even in historic times, there is ample local evidence to show. This branch of the subject, however, is scarcely yet ripe for discussion, nor would space here allow it to be fully entered into.

Baron Ettingshausen and myself are preparing a monograph upon the ferns of this flora which I hope very shortly to place in the hands of the Palæontographical Society.

J. S. GARDNER

THE TELEPHONE

AT the Society of Telegraph Engineers on the evening of October 31 a lecture of great interest was given by Prof. Graham Bell on the Telephone, with the invention and improvement of which his name is so intimately connected. The lecture was largely illustrated by diagrams, to which Prof. Bell made constant reference, and with these illustrations will be published at length in the forthcoming part of the *Journal* of the Society. We have already given a full account of the telephone and its principles, and will only now refer to some of the interesting episodes which occurred in the course of Prof. Bell's experiments.

Prof. Bell's account of his experiments for devising methods of exhibiting the vibrations of sound, specially for use in teaching the deaf and dumb, is very interesting. For some time he carried on experiments with the manometric capsule of Koenig, and with the phonautograph of Léon Scott. He was led to the idea of constructing a phonautograph modelled closely on the mechanism of the human ear, and at the suggestion of Dr. C. J. Blake, he made use of the human ear itself, a specimen of which was prepared by Dr. Blake, for conducting these experiments.

It occurred to him that if a membrane as thin as tissue paper could control the vibration of bones that were, compared to it, of immense size and weight, why should not a larger and thicker membrane be able to vibrate a piece of iron in front of an electro-magnet, in which case the complication of steel rods in his first form of telephone could be done away with, and a simple piece of iron attached to a membrane be placed at either end of the telegraphic circuit.

The form of apparatus he was then employing for producing undulatory currents of electricity for the purposes of multiple telegraphy he describes thus: a steel reed was clamped firmly by one extremity to the uncovered leg of an electro-magnet, and the free end of the reed projected above the covered leg. When the reed was vibrated in any mechanical way, the battery current was thrown into waves, and electrical undulations traversed the circuit, throwing into vibration the corresponding reed at the other end of circuit. He immediately proceeded to put his new idea to the test of practical experiment, and for this purpose he attached the reed loosely by one extremity to the uncovered pole of the magnet, and fastened the other extremity to the centre of a stretched membrane of goldbeater's skin. He presumed that upon speaking in the neighbourhood of the membrane it would be thrown into vibration and cause the steel reed to move in a similar manner, occasioning undulations in the electrical current that would correspond to the changes in the density of the air during production of the sound; and he further thought that the change of the intensity of the current at the receiving end would cause the magnet there to attract the reed at that end in such a manner that it should copy the motion of the reed at the transmitting end, in which case its movements would occasion a sound from the membrane there similar in *timbre* to that which had occasioned the original vibration.

The results, however, were unsatisfactory and discouraging. With a reduction, however, in the size and weight of the spring employed, distinctly audible effects were obtained. "I remember," Prof. Bell said, "an experiment made with this telephone, which at the time gave me great satisfaction and delight. One of the telephones was placed in my lecture-room in the Boston University, and the other in the basement of the adjoining building. One of my students repaired to the distant telephone to observe the effects of articulate speech, while I uttered the sentence, 'Do you understand what I say?' into the telephone placed in the lecture-hall. To my delight an answer was returned through the instrument itself, articulate sounds proceeded from the steel spring attached to the steel membrane, and I heard the sentence, 'Yes, I understand you perfectly.' It is a mistake, however, to suppose that the articulation was by any means perfect, and expectancy no doubt had a great deal to do with my recognition of the sentence; still, the articulation was there, and I recognised the fact that the indistinctness was entirely due to the imperfection of the instrument." After a time he produced a form of instrument which served very well as a receiving telephone; and it was in this condition his invention was exhibited at the Centennial Exhibition in Philadelphia. It was in this condition also that Sir William Thomson exhibited the instrument to the British Association in Glasgow.

In pursuing his investigations Prof. Bell has come across many interesting facts which we regret we cannot refer to in detail. It has long been known that when an intermittent current of electricity is passed through the coils of an electro-magnet a musical tone proceeds from the magnet. "I have discovered," he said, "that these sounds are not due wholly to sudden changes in the magnetic condition of the iron core, as heretofore supposed, but that a portion of the effect results from vibrations in the insulated copper wires composing the coils. An electro-magnet was arranged upon circuit unto an instrument for interrupting the current, the rheotome being placed in a distant room so as to avoid interference with the experiment. Upon applying the ear to the magnet a musical note was clearly perceived, and the sound continued after the iron core had been removed from the coils. The effect may probably be explained by the attraction of the coils for one another during the passage of the galvanic current and the sudden cessation of such attraction when the current ceased. It is probable, too, that a molecular vibration is occasioned in the conducting wire by the passage of an intermittent current. I have found that very distinct sounds proceed from straight pieces of iron, steel retort-carbon, and plumbago, when an intermittent current is passed through them."

When a powerful current is passed through the body a musical note can be perceived when the ear is closely applied to the arm of the person experimented upon. The sound seems to proceed from the muscles of the forearm and from the biceps muscle. Mr. Elisha Gray has also produced audible effects by the passage of electricity through the human body. An extremely loud musical note is occasioned by the spark of a Ruhmkorff's coil when the primary circuit is made and broken with sufficient rapidity; when two rheotomes of different pitch are caused simultaneously to open and close the primary circuit a double tone proceeds from the spark.

A curious discovery has been made by Prof. Blake. He constructed a telephone in which a rod of soft iron, about six feet in length, was used instead of a permanent magnet. A friend sang a continuous musical tone into the mouth-piece of a telephone, which was connected with the soft iron instrument alluded to above. It was found that the loudness of the sound produced in this telephone varied with the direction in which the iron rod was held, and that the maximum effect was produced when the rod was in the position of the dipping needle.

This curious discovery of Prof. Blake has been verified by Prof. Bell.

"Prof. Peirce has observed the most curious sounds produced from a telephone in connection with a telegraph-wire during the aurora borealis; and I have just heard of a curious phenomenon lately observed by Dr. Channing. In the City of Providence, Rhode Island, there is an over-house wire about one mile in extent with a telephone at either end. On one occasion the sound of music and singing was faintly audible upon one of the telephones. It seemed as if some one were practising vocal music with a pianoforte accompaniment. The natural supposition was that experiments were being made with the telephone at the other end of the circuit, but upon inquiry this proved not to have been the case. Attention having thus been directed to the phenomenon, a watch was kept upon the instruments, and upon several subsequent occasions the same fact was observed at both ends of the line by Dr. Channing and his friends. It was proved that the sounds continued for about two hours, and usually commenced about the same time. A searching examination of the line disclosed nothing abnormal in its condition, and I am unable to give you any explanation of this curious phenomenon. Dr. Channing has, however, addressed a letter upon the subject to the editor of one of the Providence papers, giving the names of such songs as were recognised, with full details of the observations, in the hope that publicity may lead to the discovery of the performer, and thus afford a solution of the mystery."

Prof. Bell referred to some experiments made by Mr. F. A. Gower and himself to show the slight earth connection required to establish a circuit for the telephone.

"One experiment which we made is so very interesting that I must speak of it in detail. Mr. Gower made earth connection at his end of the line by standing upon a grass plot, whilst at the other end of the line I stood upon a wooden board. I requested Mr. Gower to sing a continuous musical note, and to my surprise the sound was very distinctly audible from the telephone in my hand. Upon examining my feet I discovered that a single blade of grass was bent over the edge of the board, and that my foot touched it. The removal of this blade of grass was followed by the cessation of the sound from the telephone, and I found that the moment I touched with the toe of my boot a blade of grass or the petal of a daisy, the sound was again audible."

Prof. Bell concluded as follows:—"The question will naturally arise, through what length of wire can the telephone be used? In reply to this I may say that the maximum amount of resistance through which the undulatory current will pass, and yet retain sufficient force to produce an audible sound at the disturbed end, has yet to be determined; no difficulty has, however, been experienced in laboratory experiments in conversing through a resistance of 60,000 ohms, which has been the maximum at my disposal. On one occasion, not having a rheostat at hand, I may mention having passed the current through the bodies of sixteen persons, who stood hand in hand. The longest length of real telegraph line through which I have attempted to converse has been about 250 miles. On this occasion no difficulty was experienced so long as parallel lines were not in operation. Sunday was chosen as the day on which it was probable other circuits would be at rest. Conversation was carried on between myself, in New York, and Mr. Thomas A. Watson, in Boston, until the opening of business upon the other wires. When this happened the vocal sounds were very much diminished, but still audible. It seemed, indeed, like talking through a storm. Conversation, though possible, could be carried on with difficulty, owing to the distracting nature of the interposing currents.

"I have had the opportunity of testing the telephone upon the artificial cable owned by Sir William Thomson. No difficulty was experienced in conversing through the equivalent of 120 miles of submarine cable. Vocal sounds were audible when the equivalent of the whole Atlantic cable was interposed between the two telephones, but the sounds were so faint that conversation could not be carried on. Songs that were sung into one telephone were readily recognised at the other end of the circuit, and the articulation of pre-arranged sentences was readily recognised. That the sounds were electrically produced was evident from the fact that they ceased when the circuit was broken and when the coils of the telephone were short circuited. No difference was observed between the pitch of the note which was transmitted through the artificial cable and the same note when transmitted directly through the air. The artificial cable experimented upon had four times the resistance of the Atlantic cable, and one-fourth its electrostatic capacity. I am informed by my friend, Mr. Preece, that conversation has been successfully carried on through a submarine cable, sixty miles in length, extending from Dartmouth to the Island of Guernsey, by means of hand telephones."

In a lecture on the 8th inst. at Glasgow, Prof. Bell, referring to the use of the telephone in mines, pointed out how the instrument might be of the greatest service in determining whether the ventilation of a mine was perfect or not; for by listening to the telephone, if the mine was in good order, a little sound could be heard every moment.

AFRICAN EXPLORATION

MR. STANLEY'S letter and the map in the *Telegraph* of Monday enable us to realise somewhat more fully the nature and extent of the discoveries made by the intrepid traveller. Mr. Stanley is bent on calling the great river, so much of which he has explored, by the name of Livingstone. As a rule we think it a mistake to change native geographical names where these can be satisfactorily ascertained. In the case of the Lualaba-Congo, however, the river seems to have quite as many names as there are tribes or villages on its banks, and it would be a happy solution of the difficulty to confer upon it the most memorable name among African explorers. Mr. Stanley himself has taken great pains to obtain accurately the native names of tribes and places, and he animadverts with severity on geographers for crowding the map of Africa with names that probably correspond to nothing. For this they cannot be greatly blamed, neither need he be too hard on previous travellers for misunderstanding the significance of native words.

A glance at the map, notwithstanding that it is based to some extent on conjecture, shows at once the vast importance of Mr. Stanley's discovery. Great tributaries join the main river from both sides, and we are assured there are many more besides these shown on the map. For more than 800 miles of its course, above the Yellala Falls, the river looks more like a long winding lake than anything else, forming a magnificent channel for navigation. Above the upper cataract, again, about the equator, many other long reaches are capable of navigation, while the affluents will afford over 1,200 miles, and perhaps much more. Some idea of the increasing magnitude of the river below Nyangwe may be obtained from Stanley's statement that at Nyangwe the volume is 124,000 cubic feet per second, while Behm's calculation on the basis of Tuckey's trustworthy observations makes its volume at the mouth to be 1,800,000 cubic feet per second. Poor Tuckey comes in for a share of Stanley's castigation, because, according to Stanley, the former mistook the number of stages of the Yellala Rapids; even if Tuckey was a little out in his counting, which we doubt, he will still be found to have been, all circumstances considered, an accurate observer. Many points, also, in connection with the map, show how true was Livingstone's geographical instinct, and how near the truth his inferences came from the information obtained from the Arabs and natives. Stanley is probably right in conjecturing that the Aruwimi, coming from the north-east, and joining the Livingstone a little north of the equator, is the Welle, and that the Ikelemba is the lower course of the Kasai. The water of the latter is of the colour of tea, and does not thoroughly mingle with the main stream until after 130 miles below the confluence. The banks of the great river are thickly populated by what appear to be industrious people living in extensive and well laid out towns, and naturally jealous of intruders. The three most powerful tribes on the middle and lower rivers are the Wa-Mangala, the Warunga, and the Wyanzi.

The Livingstone, Mr. Stanley found, is subject to periodical rises mainly owing to the rains, and varying from eight to fifty feet. The entire length of the Livingstone Mr. Stanley calculates at 2,900 miles, and its basin at 860,000 square miles. The extreme sources of the Bemba Lake, from which the Luapula flows, are in 33° E. long. Lake Bemba, or Bangweolo, Stanley states—and there appears to be good ground for the belief—is the residuum of an enormous lake that in very ancient times must have occupied an area of 500,000 square miles, "until by some great convulsion the western maritime mountain chain was riven asunder, and the Livingstone began to roar through the fracture." As to the "great convulsion" and the "fracture," geologists may be able to decide when they are in possession of full information as to Mr. Stanley's observations. Nyangwe, Mr. Stanley informs us, is in 4° 16′ S., and 26° 5′ E.; but by an unaccountable mistake in another place he gives the latitude as 26° 15′ 45″, and that, too, while pointing out, in his peculiar way, a slight mistake in the position on Stanford's map of 1874. The position then was perfectly correct according to the data, and in the latest editions the position is exactly as Stanley gives it.

Mr. Stanley insists on the importance of the river as a commercial highway, the country traversed by it being abundantly rich in products that would find a ready market in Europe. Naturally, on Monday night, Africa was the burden of the president's address at the opening of the Geographical Society. Sir Rutherford Alcock insisted that it now remained with the merchant, aided if need be by Government, to open up Africa still further. Indeed the country is now being attacked by national and private expeditions on all sides, and if a basis for minute exploration were formed by trading stations under government sanction and regulation, along the Livingstone, our knowledge of the country would grow rapidly, and the benefits to commerce would be incalculable. Only, however, could the natives have fair play by governmental regulation of private enterprise. There is no danger of extinction for the native African, and it would be both prudent and just to protect him from the horrible cruelties at which Mr. Stanley hints in the conclusion of his letter.

It is worth noticing that in the map the Lukuga runs boldly from Lake Tanganyika and joins the Lualaba, and the source of the Alexandra Nile is brought to near 4° south on the east side of the lake.

According to latest intelligence Mr. Stanley is at the Cape wanting to get his followers sent back to Zanzibar. In his letter in yesterday's *Telegraph* he gives an interesting account of his companion, Frank Pocock, of whom he speaks in the highest terms, and whose death is a real loss to African exploration.

The *Daily News* Alexandria Correspondent writes (on the 5th) that Signori Gessi and Matteucci have just started from Cairo for Khartum, *viâ* Assouan, by the Nile, instead of taking the shorter route by the Red Sea to Massowa. They are provided with the newest and most improved scientific instruments, and having promised to keep up constant communication with the Geographical Society at Rome, interesting accounts of their movement and progress will be looked for.

MODERN TORPEDO WARFARE

TWO elements have contributed to make torpedo warfare what it is: electricity and the new explosive compounds. It is true that in the Whitehead or fish torpedo recourse is had only to the latter of these, but it is the sole material exception, and all the mischief effected by this branch of marine warfare has been, so far, the result of electric torpedoes. Both on the Danube and in the last American war, when no less than twenty-five ships were sunk by the Confederates, the electric torpedo has worked extensive injury, and it is no wonder therefore that a keen interest should be taken in all that pertains to so novel and destructive a method of killing and wounding.

We have called the torpedo a novel weapon, and the instruments that go by the name to-day undoubtedly are so. At the time of the Crimean war, we had to do with torpedoes of a kind; nay, even so far back as the beginning of the seventeenth century, floating charges, called petards, were employed, but these were of too insignificant a nature to merit attention. The "infernal machines" strewn in the Baltic by the Russians twenty years ago were small canisters of powder containing by way of igniting arrangement a mixture of chlorate of potash and sugar, together with a glass bulb with sulphuric acid; and the latter, escaping from its envelope when this was broken by a shock or collision, brought about an immediate explosion. These mechanical torpedoes had two disadvantages; the igniting arrangement was of such a character that it could be set in action just as well by friend as by foe, and the explosion of the gunpowder was insufficient to effect any material injury. All this has been remedied. Electricity is nowadays employed as the igniting agent, and those terribly violent explosives, gun-cotton and dynamite, replace the comparatively innocuous gunpowder.

Electric torpedoes may be broadly divided into two classes: offensive and defensive torpedoes. The latter are employed for the protection of harbours, channels, and roadsteads; the former, in the shape of drifting or spar-torpedoes, are carried to the attack in small swift-sailing steam-launches. In this country we are favourably disposed to the employment of compressed gun-cotton in our machines, while on the Continent they seem to entertain a predilection for nitroglycerine, or rather dynamite. Both compounds are what chemists term nitro-compounds, in contradistinction to gunpowder, which comes under the class of nitrate-compounds, and appear to exercise an explosive force of almost similar violence, measuring the substances weight for weight. Compressed gun-cotton, we need hardly say, is cotton yarn acted upon by nitric and sulphuric acids and then pulped and washed, so that the result is a finely-divided mass which may be made to assume any shape or form. As a rule the material is pressed into cakes of disc-like form, which weigh from a few ounces to a pound, and while still wet the slabs are stored away in the magazines. In this moist condition the compressed pulp is not only non-explosive, but actually non-inflammable, except one possesses the key to its detonation. This is nothing more than a dry cake of the same material, or as the latter is termed in military parlance, a "primer," which on being detonated by a few grains of fulminate, brings about the explosion of any wet gun-cotton in its immediate neighbourhood. Thus if simply a net is filled with gun-cotton slabs and thrown into the sea, the whole charge may be ignited by a primer contained in a waterproof bag having an electric fuze and wire attached. The possibility of communicating explosion in this way by vibration instead of by spark or flame is, too, as we shall presently see, the germ of a system of counter-mining, or torpedo annihilation, which bids fair to develop into a particularly effective means of defence against these terrible machines. Dynamite is similarly exploded to gun-cotton. The active principle in this case is nitro-glycerine, or, if you will, liquid gun-cotton, prepared by simply allowing glycerine to fall drop by drop into nitric acid. As a solid is usually more convenient to handle than a liquid, the use of pure nitro-glycerine has given way to dynamite, which may be described as siliceous earth impregnated with the explosive fluid.

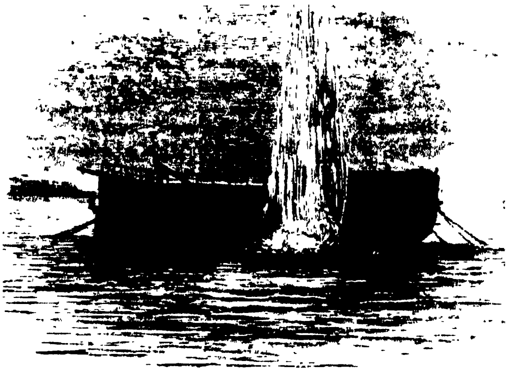

FIG. 1.—Fish Torpedo exploding against a ship.

Dynamite and gun-cotton explode with something like four or five times the force of gunpowder, and for this reason a very destructive charge may be confined within a comparatively small space. Moreover they are peculiarly adapted to submarine mines, since nitro-glycerine is no more affected by water than gun-cotton; and the old adage "to keep your powder dry" does not apply to either of them. In the case of moored torpedoes which are connected with batteries to the shore or carry their own means of generating electricity, as in the Herz topedo of our German cousins, there is no limit to size, and machines containing as much as 500 lbs. of gun-cotton have, in fact, been constructed; but for a spar-torpedo, or in other words one which is thrust under an enemy's keel by means of a thirty-foot pole projecting from the prow of a launch, the charge must be considerably smaller, and for two reasons. A great weight at the end of such a lever could not be properly manipulated, while the explosion, if the charge were a very large one, would destroy both the attacking and attacked. A big moored torpedo of 500 lbs. has been found, when sunk in thirty or forty feet of water, to be fatal to a strong ironclad if the latter happens to be within this distance of the source of explosion; or, in other words, a cushion of water forty feet in thickness is not sufficient to secure the immunity of such a vessel. What would happen if this terrible volcano were to erupt—if we may use the word—in contact with the sides of an armoured ship, must be left to the imagination; but despite Mr. Ward Hunt's opinion to the contrary, we do not think it would require three such torpedoes successfully exploded, to bring our boasted *Inflexible* to grief. And in this opinion our readers, we suspect, will fully agree, when we inform them that a heavy torpedo like this throws up a cone of water sixty feet in height, with a diameter at its base of no less than 220 feet. Such an heaving of waters, if it did not break the back of an ironclad, as there is every reason to suppose it would, must inevitably capsize her without more ado. But it is, of course, only on very rare occasions that such a monster torpedo could be brought to bear, and in all cases of attack the charge must needs be considerably less. The smaller Whitehead torpedoes, which, as our readers know very well, are narrow cigar-shaped weapons, that move through the water by the agency of compressed air, do not in all probability carry more than a 40 lb. or 50 lb. charge in the head, while a spar or drift torpedo of 100 lbs. is already as large as would be convenient to handle. At the same time either of these would quite suffice to fracture an iron plate several inches in thickness, and therefore be fatal, probably, to any ironclad afloat, supposing there was no water-cushion between the craft and the torpedo. We have no definite information respecting the size or weight of the torpedoes which sank the Turkish monitor in the Matchin Canal, but as the expedition was hastily arranged and organised, the charges were, no doubt, not very large.

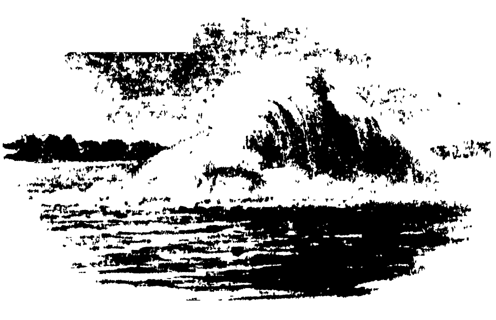

FIG. 2.—A moored Torpedo exploding. Height of column 60 feet, base 220 feet.

The fish torpedo is a rare example of a complicated apparatus coming into practical use, and its elaborate construction and fine workmanship may be imagined when the reader is informed that the machines cost 500*l.* a piece to manufacture. The long tube is divided into three compartments: the head, which contains the explosive charge, the reservoir, in which the compressed air is stored, and the machinery by means of which the stored-up energy is converted into a propelling force. The air is compressed to the extent of 600 lbs. on the square inch, and to bring about this result an exceedingly powerful air-pump is necessary, which forms an additional item of expense in the case of this torpedo. The latter when properly charged will do a journey of a mile, or mile and a half, under water, the first 1,000 yards being got over at a rate of no less than twenty miles an hour, and if unaffected by tide or current, the machine will proceed in a perfectly straight direction. It floats at any distance under water that may be desirable, but is usually made sufficiently buoyant to swim at eight feet from the surface; it explodes on striking any object, but the machine is so contrived that if it fails to strike, then it floats to the surface, and a trigger guard renders the fish at the same time innocuous, and permits of its recapture without risk. Ingenious as the little creature is, there has been, we repeat, no authenticated employment of it during the present war.

On the Danube the spar-torpedo alone seems to have been used against Turkish monitors. As in the case of the *Thornycroft* launch, of which we are to have a flotilla of thirty in the British navy, the torpedo is projected at the end of a spar, and is ignited either by concussion or by electricity. The Turkish ironclad at Matchin was the victim of two torpedoes of this class, the first of which, we are told, was ignited by the crew of the launch by electricity, and the other on concussion with the vessel attacked. These Russian torpedoes are said to be innocuous at a distance of ten feet from the seat of explosion, and hence those in the launch do not suffer much except from the water that is thrown into the air. From the fact that small batteries in the boat are used to fire the charges, we may safely conclude that their explosion is brought about by a platinum wire fuze, which, together with a few grains of fulminate, would determine the detonation of dynamite or gun-cotton. Each launch is provided with a pair of these spar torpedoes, carried, when not in action, on each side, running the length of the boat, and only on making an attack is one or other projected at the bow, the torpedoist being stationed behind a shield, or under an iron screen, where he can make his observations tolerably free from danger.

In the case of moored torpedoes depending for their ignition upon electricity, many points of scientific interest have recently been brought to light. Some experiments undertaken in Denmark two or three years ago showed most conclusively that dynamite torpedoes cannot be placed close together without incurring the danger of one charge bringing about the explosion of others. A dynamite torpedo of 150 lbs. ignited in ten feet of water, was found capable of exploding other charges at a distance of 300 feet by the mere vibration imparted to the water; so that in constructing coast defences with dynamite torpedoes it is absolutely necessary to keep them far apart from one another. Another point was also noted. A current of electricity, if it emanates from a powerful frictional electric machine, traversing one of a bundle of wires, will induce a current in the other wires, and thus bring about the explosion of torpedoes other than that which the operator on shore desires to ignite. It is these facts particularly which have led to the development of a system of counter-attack and have enabled our sailors to devise a means of defending themselves from the terrible sea-monsters. Both dynamite and gun-cotton are peculiarly sensitive to vibration—indeed their detonation, as we have seen, is brought about by no other cause—and hence a captain of a man-of-war by exploding countermines in his vicinity may soon get rid of any lurking torpedoes lying in wait for him, at any rate if they contain a nitro-glycerine compound, and so speedily clear a way for his ship.

This is certainly subject for congratulation, for it seemed at one time as if the poor sailor was absolutely defenceless against these submarine abominations. A crinoline of spars and wire rope may be employed to catch the fish torpedo and explode the vermin harmlessly in its toils, provided the ingenious brute is not a very large one, and the net is at some distance from the ship; but heavy moored torpedoes have been hitherto considered too dangerous to approach, so that marine countermining must prove invaluable. The spar or drifting torpedo cannot be dealt with by nets or booms alone, and in this case the only plan would seem to be to meet attack with attack and beat off launches with other small boats. That all ironclads in time of war will have to be surrounded by lesser craft as a protection is a matter that we may now take for granted, as also that such vessels must be provided with some powerful means of illumination—the electric light, for instance—to prevent swift, low-lying torpedo launches from approaching unperceived at night time.

Special schools of instruction for acquainting officers with the science of electricity and explosives have for some time past been established, and there is indeed scarcely a naval power which has not paid attention to submarine warfare; consequently we may expect to see future battles upon the sea carried on just as much under water as above it. In this country we have a torpedo school on board H.M.S. *Vernon* at Portsmouth, while at the Royal Naval College at Greenwich instruction in the experimental sciences now forms one of the most important items in the curriculum. France has its naval torpedo school at Boyardville, where both officers and seamen are made acquainted with the principles of submarine warfare. Germany, as all the world knows, practised torpedo warfare to such good purpose seven years ago that the magnificent fleet of the French never once ventured to visit the coast of the Fatherland. Both at Kiel and at Wilhelmshaven are to be found torpedo depôts and a well-organised staff of instructors. Lastly the news comes to us from Russia that the Czar has sanctioned the organisation of a distinct torpedo service, and two depôts and instructional schools are to be formed at Kertch and Cronstadt, whence torpedo appliances are to be issued for the defence of the Baltic and the Black Sea.

NOTES

MR. DARWIN will receive the honorary degree of LL.D. at Cambridge on Saturday next, at 2 P.M., at a congregation specially convened for the purpose. In the evening the annual dinner of the Philosophical Society will take place in the Hall of Clare College, when a brilliant gathering is expected to meet the illustrious visitor, among the non-resident guests being Profs. Huxley, Tyndall, and Parker, and Sir John Lubbock.

THE Postmaster-General of the German Empire is about to have an extensive series of experiments made with a view to the introduction of the telephone into the telegraphic service. Several hundred specimens of the telephonic apparatus manufactured by Siemens and Halske have been ordered.

THE French Ministry had granted a pension to the widow of Leverrier. Unfortunately the lady died, as we mentioned in our last number, before the first monthly instalment became due. It is hoped that a part of the pension will go, against ordinary rules, to the son and daughter of the astronomer.

THE Minister of Public Instruction has been authorised by a decree of the President of the French Republic to accept a sum of 8,000*l.*, bequeathed by Madame Thuret, in order to establish at Antibes, in the Department of Alpes Maritimes, an agricultural station connected with the lectureship on Agriculture and Botany of the Paris Museum of Natural History.

MR. PARK HARRISON has completed the exploration of the galleries belonging to the "Cave Pit" at Cissbury—in which rune-like characters were found in 1875—and found that they communicate with galleries connected with other shafts, at distances of from 20 to 30 feet, on the north, west, and east sides. Mr. Harrison thinks there appears to be sufficient evidence that they were used for purposes of shelter or concealment long after they were originally excavated. One of the shafts last cleared out, was found to have been left in an incomplete state, as if the work had been for some reason interrupted. On the south of the cave pit, and immediately adjoining it, Mr. Harrison has discovered several small pits, the largest being 5 feet in diameter, and 4 feet 6 inches deep. All contained flint flakes, sling-stones, and a few bones. In some there were small ornaments, pots of good quality, bone combs, terra-cotta beads, and hard polishing-stones. In one pit there was an iron hook.

THE following testimony from so competent and disinterested an observer as Prof. Monier Williams to the necessity for systematic meteorological observation in India is valuable, and we hope will have weight with the proper authorities. In the last of his series of articles on his second tour in India, in the *Times* of November 7, Prof. Williams writes thus:—"One thing requires instant attention. The connection between agriculture, meteorology, and astronomy is now admitted on all hands, and no country in the world would be benefited more than India by systematic meteorological and astronomical observations carried on under Government direction. Much is already being done in this way. Yet I could only find one effective astronomical observatory, and that not adequately supported by Government, though I travelled from Cashmere to Cape Comorin. It is not generally known that from his observations of the present condition of the disc of the sun, in connection with various atmospherical phenomena, the Madras astronomer, Mr. Pogson, prophesied in 1876 a recurrence of the drought and famine in 1877."

ON October 24, we learn from *L'Exploration*, Signor D'Albertis and Prof. Od. Beccari left Genoa in the steamer *Australia* for a year's voyage round the world. They will first visit Egypt, and thence to India, China, and Japan, returning to Europe by New York. They intend to collect during their voyage birds, mammals, and insects for the museums of Italy, principally for that of Genoa.

FOR several years past Major J. W. Powell, in charge of the United States Geographical and Geological Survey of the Rocky Mountain Region, has been paying particular attention in his researches, to the ethnology and philology of the American Indians; and having received from the Smithsonian Institution an immense mass of material on this subject, collected during a period of many years, he has called to his assistance numerous experts for the purpose of preparing a series of memoirs on these topics. We have now a partial result of his labour in the first of a series of quarto volumes, entitled "Contributions to North American Ethnology," and published in most excellent style, with numerous illustrations, at the Government Printing-office. The present volume is occupied with the Indians of North-western America, embracing several papers by Mr. Dall and others on the tribes of Alaska and adjacent territories, and a number of vocabularies, principally by the late Mr. George Gibbs.

OUR readers may remember that last spring Capt. Burton made an expedition into the Land of Midian, which lies to the south-east of the Gulf of Akaba, in the Red Sea. He was accompanied by a mining engineer, M. Marie, and the two explorers came upon traces of extensive mining operations, the ruins of ancient towns, and many other evidences of a flourishing mining district. They brought back specimens containing gold, silver, copper, and other metals, and were most sanguine as to their discovery. Capt. Burton is now again in Egypt, the *Times*' Alexandria correspondent writes, preparing another expedition to Midian. He is now determined to investigate thoroughly that biblical country of which he only got a superficial idea in his twenty-day visit last spring. His intention now is to penetrate to the mountains in the interior, and thoroughly satisfy himself as to their nature and capabilities. He estimates the distance under twenty days' march. It is a curious fact that these mines were known to the ancients so long ago as the time of Ramses III., whose cartouche is inscribed on the Needle which is on its way to England. In the Harris Papyrus in the British Museum is a passage referring to the copper mines of Akaba.

AT the last meeting of the Russian Geographical Society, the Secretary gave some account as to this year's expeditions sent out by the Society. The results of Prshevalsky's expedition are a survey from Kuldja for 800 miles into the interior of the country, seven determinations of latitudes and longitudes, many barometrical measurements of heights along the route, a botanical collection of about 300 species, a zoological collection, numbering 85 mammalia, 180 species (500 specimens) of birds, 50 specimens of fishes, 150 reptiles, and 2,000 insects. The most important objects in the collection are four skins of wild camels. All the collections are now in Kuldja, and will be forwarded to St. Petersburg during the winter. About the end of August M. Pishevalsky had started for Tibet. M. Potanin has returned without having penetrated far into the interior of Mongolia. He proposes now to go to the sources of the Yenissei. M. Mainoff has returned from his travels among the Mordva population of Eastern Russia with very valuable materials. He has obtained anthropological measurements according to the 126 queries of the programme, of 510 individuals, and he brings detailed answers on the queries of the programme as to the ethnographical and juridical customs of the Mordva, as well as numerous skulls, photographs, tools, and dresses.

A RAILWAY official in Berlin was lately fined by the district courts for appending to his name the title of *doctor juris utriusque*, on the strength of a diploma from the University of Philadelphia. An appeal to a higher court resulted in a confirmation of the sentence.

WE notice a very useful Russian work, just published by the St. Petersburg Committee of Primary Education, being a review of all works that have appeared in Russia in the department of primary instruction. The book, 640 pages, gives a complete catalogue of such works, with critical notices on each of any importance, and it is sold at a very low price, for the use of primary teachers.

A YOUNG schoolmistress of Tlemcen (Algeria) has successfully passed her examinations before the Faculty of Aix for Baccalaureate in Letters, and has been warmly congratulated by the Board.

THE statue of Lagrange, the celebrated mathematician, born in Italy, but a naturalised Frenchman, was erected last week in the hall of the Bureau des Longitudes.

AT a recent meeting of the Paris Academy of Sciences a letter from M. Fabre to M. Dumas was read, referring to an American vine which he had cultivated for a long time in the very heart of phylloxeric centres, but which has escaped the least sign of infection. It flourishes under the most unfavourable circumstances, grows rapidly, and readily receives grafts from French vines.

THE French Association Polytechnique, created in 1830, has just published its programme for 1877-1878. Lectures are given by this institution to working men in each of the twenty municipal districts of Paris, and in almost every manufacturing district of France. For the first time the programme of lectures is uniform, and special text-books are published at a cheap rate under its authority. No salaries are given to teachers, and no fees taken from pupils. It is called "La Sorbonne de l'Ouvrier." All expenses are covered by voluntary contributions. M. Dumas, the perpetual secretary of the Institute has been elected president of the Association. He has filled this important position for a number of years.

THE *Jardin d'Acclimatation* of Paris, as we recently stated, has received a family of Esquimaux, who are quartered alongside the Nubians, who were recently in London. They consist of three men, a woman, and two children, and have charge of a collection of phocas, white bears, and trained dogs. The customary Esquimaux huts have been erected for their accommodation, and their time is spent in the ordinary occupations to which they are accustomed in the Polar regions. The *Société d'Anthropologie de Paris* has appointed a commission to study these unusual visitors, consisting of Dr. Broca, president, and MM. Bordier, Dolly, Girard de Rialle, Mazard, and Topinard.

THE Ministry of Public Instruction has just established, in Paris, a "Bibliothèque Universitaire," containing all works appearing from the pens of the professors of the French University.

AMONG the medals awarded by the Photographic Society in connection with their Exhibition, are one for the best micro-photograph, "Proboscis of a Blowfly," to Mr. Edward Viles, and a special medal to Mr. W. J. A. Grant for his Arctic Views.

THE Institution of Civil Engineers resumed its meetings on Tuesday. Among the papers announced to be read early in the session are, a "Review of the Progress of Steam Shipping during the last Quarter of a Century," by Mr. Alfred Holt, M. Inst. C.E. of Liverpool, whilst the latest development of electrical invention and its application to lighting purposes, will be discussed in a paper by Dr. Paget Higgs and Mr. Brittle, Assocs. Inst. C.E., entitled "Some Recent Improvements in Dynamo-Electric Apparatus."

THE fourth annual meeting of the Dundee Naturalists' Society was held recently. Mr. Grothe, the president, occupied the chair. The secretary read the council's report for the past year, which showed that it had been one of great activity and prosperity. The year began with a membership, including all classes, of 232, but at the date of the report this number had increased to 401, being an increase of 169. The property of the society had also been considerably increased during the year, chiefly by gifts of books and specimens for the society's museum. During the last winter nine original papers had been read by members at the ordinary meetings of the society, treating of geological, biological, physical, and archæological subjects. During the summer the interest in, and work of, the society was kept alive by a series of very attractive excursions. One excursion was a sea-dredging expedition, and opened up for the society a new field for its energies. In order to secure a more exhaustive and systematic treatment of the various branches of natural science, the society was formed into sections, three in number, viz. :—1. Physical and Chemical; 2. Geological; 3. Biological. From this arrangement it is hoped that much good will result. The society is in a very healthy and vigorous condition.

THE following modification of an experiment of Prof. Tyndall's is described by M. Terquem in the *Journal de Physique* for October. A trumpet-bell connected by a thick caoutchouc tube with one of König's manometric flames, is fixed vertically over a square plate, which is vibrated so as to give two nodal lines as in Tyndall's experiment. If the axis of the bell be placed exactly over the centre of the plate, the flame remains quite motionless, and the same if the bell be placed above a nodal line. On the other hand, the flame vibrates when the bell is displaced, however little, and the vibrations become very strong when the bell is placed above a ventral segment. With two similar trumpet-bells placed over two ventral segments having similar, or contrary movements, the vibrations may be united on a single flame, by means of a Y-tube, a drawing-tube being placed in the passage of one of the vibratory movements. The advantage of this arrangement consists in producing very strong separate vibrations; moreover, it is possible to give them exactly the same intensity by displacing laterally one of the bells. To obtain absolute motionlessness in the flame the two combined movements must have exactly the same amplitude. To render the flame more brilliant M. Terquem passes the gas through pumice-stone soaked with benzine or the like, and incloses the jet in a tube through which a current of oxygen is sent. A cylinder of mica blackened interiorly, except on the side next the revolving mirror, surrounds the flame.

A RECENTLY-PUBLISHED report by the Criminal Administration of France gives some curious statistics with regard to suicides in 1874. There were in that year 5,617 suicides, the highest number ever recorded in the country. Of these 4,435 (79 per cent.) were committed by men, and 1,182 (21 per cent.) by women. The ages of 105 of the suicides are unknown. The 5,512 others are thus divided :—Minors of 16 years, 29; 16 to 21 years of age, 193; 21 to 40, 1,477; 40 to 60, 2,214; and beyond 60, 1,599. Among the suicides there are enumerated 1,946 celibates (36 per cent.), 2,645 (48 per cent.) were married, and 881 (16 per cent.) were widowed. Of the number of those forming the last two categories there were 2,259, or nearly two-thirds, who had children. The civil state of 145 individuals could not be ascertained. More than seven-tenths of the suicides were by strangulation (2,472), or by submersion (1,514). The suicides were, as always, more frequent in spring (31 per cent.) and in summer (27 per cent.) than in winter (23 per cent.) and in autumn (19 per cent.). As to the motives, there is no information about 481 of the suicides; the others are classed as follows :—Misery and reverses of fortune, 652; family troubles, 701; love, jealousy, debauchery, misconduct, 815 (of which 572 were brought about by drunken habits); physical sufferings, 798; various troubles, 489; mental maladies, 1,622; suicides of persons guilty of capital crimes, 59.

AT the meeting of the Eastbourne Natural History Society, of October 19, Mr. Roper read an important paper on "The Addition to the Flora of Eastbourne since 1875."

THE additions to the Zoological Society's Gardens during the past week include a Tiger (*Felis tigris*) from China, presented by Mr. A. Forbes Angus; a Macaque Monkey (*Macacus cynomolgus*) from India, presented by Mr. H. W. Henderson; a Saker Falcon (*Falco sacer*) from Egypt, presented by Mrs. Arthur Coote; two Grey Plovers (*Squatarola helvetica*), a Ringed Plover (*Œgialitis hiaticula*), a Dunlin (*Tringa cinclus*), European, presented by Mr. F. Cresswell; a Californian Quail (*Callipepla californica*) from California, presented by Mrs. A. H. Jamrach; a Ring Hals Snake (*Sepedon haemachates*) from South Africa, presented by Mr. Eustace Pillans; a Brown Pelican (*Pelecanus fuscus*) from West Indies, a Cape Zorilla (*Ictonyx zorilla*) from South Africa, purchased; five Reindeer (*Ranifer tarandus*) from Lapland, deposited; a Cape Buffalo (*Bubalus caffer*) from South Africa, received in exchange.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

EDINBURGH.—The Marquis of Hartington has, by a large majority over Mr. Cross, been elected Lord Rector of Edinburgh University.

PRUSSIA.—We notice from the last report of the Prussian Minister of Instruction that the present number of instructors in the ten universities amounts to 896, viz., 466 ordinary professors, 7 honorary, 199 extraordinary, and 224 *privat-docenten.* The philosophical faculties include 400, the medical, 250, the legal, 86, and the theological, 110. The number of instructors varies from 29 at Munster, to 201 at Berlin. The number of students is about nine times that of the professors, viz., 8,209, and includes 1,080 from other countries than Prussia. According to their faculties they are divided as follows: evangelical-theological, 684. catholic-theological, 289, legal, 2,261, medical, 1,340, and philosophical, 3,626. The attendance at the universities during the past summer was Berlin 2,237, Breslau, 1,245, Gottingen, 917, Bonn, 897, Halle, 827, Konigsberg, 620, Greifswald, 503, Marburg, 401, Munster, 315, and Kiel, 241.

In the budget submitted to the present Prussian House of Deputies are the following items:—Erection of the German Industrial Museum, 998,000 mk.; erection of a Polytechnic in Berlin, 8,303,370 mk.; erection of an Ethnological Museum in Berlin, 1,800,000 mk.; and for the Berlin University, erection of a Herbarium, 422,000 mk.; of a Clinic, 1,955,000 mk.; of a new building for a second Chemical Laboratory, as well as of a Technical and Pharmaceutical Institute, 967,000 mk.

BONN.—On entering upon the duties of rector of the University, Prof. Kekulé, the distinguished chemist, delivered, on October 18, a brilliant address on the scientific position of chemistry, and the fundamental principles of this science. He made the following definition of chemistry as distinct from physics and mechanics:—"Chemistry is the science of the statics and dynamics of atoms: physics that of the statics and dynamics of molecules; while mechanics considers the masses of water consisting of a large number of molecules." After rapidly sketching the growth of the present atomic theory, he claimed that the mass of results now obtained showed that chemistry was slowly but surely approaching its goal, the knowledge of the constitution of matter. In opposition to the opinion that theory should be banished from the exact sciences, he regarded it as an actual felt necessity of the human mind to classify the endless series of individual facts from general standpoints—at present of a hypothetical nature—and that it was precisely the discussion of these hypotheses which often led to the most valuable discoveries.

VIENNA.—In Vienna the question is being agitated of separating the natural sciences at the University into a separate faculty, apart from the philosophical faculty, as is the case in Strassburg and a few other universities, which have risen superior to the old mediæval classification.

STRASSBURG.—The imperial authorities have finally decided upon extensive appropriations for the new buildings of the University. They will embrace edifices for lecture-rooms, chemical and physical laboratories, and chirurgical and psychiatric clinics. The new observatory will be completed next year, and the botanical gardens are rapidly being laid out. In 1882 the University expects to occupy its new buildings.

KÖNIGSBERG.—Prof. W. Lossen, of Heidelberg, well known by his researches on hydroxylamine, has accepted a call to the Chair of Chemistry at the University of Königsberg.

UPSALA.—The University is attended at present by 1,395 students, of whom the half are included in the philosophical faculty. The corps of teachers embraces sixty-three ordinary and extraordinary professors, and fifty-four *privat-docenten.* Of these eighty-two are in the philosophical faculty.

ST. PETERSBURG.—The lectures at the St. Petersburg Ladies' High Medical School re-opened this year on October 13. One hundred and eighteen students were admitted, though a far larger number of applicants passed the examination. The number of the students admitted, however, was limited as above because of want of room. A fifth class has now been added, and the students receive, after having finished the studies, the degree of surgeons.

SOCIETIES AND ACADEMIES

LONDON

Linnean Society, November 1.—Prof. Allman, F.R.S., president, in the chair.—Messrs. S. M. Samuel and P. Wyatt Squire were duly elected fellows of the Society.—A communication was read by Dr. G. King on the source of the winged cardamom of Nepal. By Dr. Pereira it had been regarded as the produce of *Amomum maximum*, Roxb.; but this is indigenous to Java. Roxburgh named two Indian species, *A. aromaticum* and *A. subulatum*, and Dr. King shows that the latter is the so-called winged cardamom of Nepal, its true habitat being the Morung mountains and not the Khasia hills as asserted by Voigt.—There followed a paper by Capt. W. Armit on Australian finches of the genus *Poephila.* Mr. Gould had recognised two birds, *P. gouldiae* and *P. mirabilis*, as good and distinct specific forms, a statement questioned by Mr. Diggles at the Queensl. Phil. Soc., 1876. Capt. Armit having studied the live birds in their native haunts gives his evidence in favour of Mr. Gould as to the just separation of the said Australian finches.—The self-fertilisation of plants formed the subject of an interesting paper by the Rev. G. Henslow, a notice of which we shall give elsewhere.—Mr. Ed. J. Miers gave a revision of the Hippidea." This group of the Anomourous Crustacea, although, by their elongated carapace and antennæ bearing considerable resemblance to certain of the Corystoidea, to wit the Chilian, *Blepharipoda spinnimana* and *Pseudocorystes sicarius*, yet the author considers their true affinities to be with the Oxystomatous Brachyura, through the Raninidæ. The Hippidea inhabit all the warmer temperate and tropical seas of the globe. Their life history and habits lately have received considerable elucidation at the hands of Mr. S. J. Smith, of Connecticut, in a study of the development of the common species of the eastern shores of the United States. Their limits are restricted northwards by the cold winters. The *H. talpoida* lives gregariously, burrowing in the loose, changing sands near low-water mark. Other species, however, inhabit deep water, such as the *Albunea guerinii* in the Gulf of Algiers, &c.—Mr. E. M. Holmes laid before the meeting the late Dr. Hanbury's collection of cardamoms (from the Pharmaceutical Society) in illustration of Dr. King's paper above mentioned; he also drew attention to an undetermined fungus in a sugar cane, which mould had caused the destruction of a plantation in South India.—The Rev. T. H. Sotheby exhibited branches of two remarkable shrubs, *Colletia cruciata*, Hook., and *C. Bictonensis*, Lindl., grown in Lady Rolles' garden at Bicton. These South American plants it seems, are not unknown in this country (one Fellow present stating he possessed them now in flower), but the history of their introduction, nevertheless, is a curious one.—Dr. Masters showed an unusual specimen of a grape within a grape, viz., adventitious fruit developed in place of the normal seeds; he also explained the *rationale* of adventitious tubers producing buds on the root of some examples of *Brassica Rapa* exhibited by him.—Some twigs and flowers of British grown gum trees were shown by Mr. A. O. Walker, among others *Pentstemon Clevelandii* said to have flowered here for the first time.

Physical Society, November 3.—Prof. G. C. Foster, president, in the chair.—The following candidate was elected a member of the Society: Alexander Jesseman.—Prof. McLeod described some experiments he has recently made to determine the exact number of vibrations of tuning forks by means of the apparatus he exhibited to the Society on April 28 last, and which was designed for determining slight variations in the speed of machinery or other analogous purposes. He has studied two sets of forks belonging to the Physical Laboratory at [illegible] his results exhibit a remarkable concordance, the extreme results in the worst set of observations on a fork of 256 complete vibrations only differing by 0·005 per cent., and in a good set they agreed within 0·00078 per cent. Examining the new series from 256 to 512, he found them to give from 0·3 to 0·5 of a vibration more than was anticipated, but as this variation may be due to a difference between the temperature and that at which they were adjusted, he is waiting to ascertain what this was. He considers also that the manner in which the fork is held has an effect on its vibrations, and he hopes to be able to get some information as to the effect of temperature on elasticity.—Dr. Huggins exhibited some artificial gems recently prepared by M. Feil, the well-known glass manufacturer of Paris, who has succeeded in crystallising stones of the corundum class.

Y 23353

Rubies, as well as a topaz and emerald, were exhibited. Dr. Huggins believes that the colour is imparted by small quantities of metallic oxides, and that the mass is mixed with boracic acid and maintained in a fused condition for a considerable period. M. Feil hopes to obtain larger stones by maintaining the heat constant for several weeks consecutively.—Dr. Lodge then read a communication from Professors Ayrton and Perry, of the Imperial College, Japan, in continuation of one read to the Society on May 26 last, on ice as an electrolyte, and since published in the *Philosophical Magazine*. The experiments therein described led them to expect a very sudden rise in the specific inductive capacity as the temperature of the ice increased through zero and it became water. Recent results have shown that, though rapid, this increase is not as great as they anticipated, and, whereas at - 12° C. the capacity is 0·002 microfarads, at + 5° C. it is 0·1185 microfarads, and after this temperature the increase was so rapid as to render exact readings difficult. Referring to Prof. Clerk Maxwell's theory in which he compares electromagnetic disturbances with light vibrations, they point out that he exclusively regards a conducting medium. But they showed in a former paper that no dielectric can be considered non-conducting, hence they conclude that the measured specific inductive capacity can never be even approximately equal to the square of the index of refraction. Prof. Foster mentioned that he recently had occasion to collect as many results as possible on specific inductive capacity and refractive index, and he found that, where these figures were low, the agreement with the law was fairly close, but with greater values the inductive capacity and the square of the refractive index separate very rapidly.—Prof. Guthrie described a simple means for showing the interference between two plane waves by means of two long cords vibrating side by side. If a vibration of considerable amplitude be imparted to them, and the plane in which they travel be carefully examined, two faint black lines will be seen, which cross and recross each other more rapidly as the cords are less and less in unison, and with perfect unison remain stationary.

Royal Microscopical Society, November 7.—Mr. H. C. Sorby, president, in the chair.—A paper was read by Mr. Thos. Palmer on the study of evergreens by means of the micro-spectroscope, in which he described the results of his examination of solutions of the colouring matters, oils, &c., from the leaves in various stages of growth. The paper was illustrated by drawings and by the exhibition under the micro-spectroscope of some of the solutions referred to.—A paper by Mr. F. A. Bedwell on the building apparatus of *Melicerta ringens*, was read by the secretary. It minutely described the structure and functions of those organs, and was an important addition to the number of contributions to the history of this beautiful rotifer. The paper was illustrated by drawings, some of which were enlarged upon the black board by Mr. Charles Stewart.—A paper was taken as read on the lachrymal gland of the turtle, by Mr. Charles Stewart.

PARIS

Academy of Sciences, November 5.—M. Peligot in the chair.—The following papers were read:—On some applications of elliptic functions (continued), by M. Hermite.—*Résumé* of a history of matter (third article), by M. Chevreul. This comprises from the thirteenth to the seventeenth century.—On the hydrogenation of benzine and aromatic compounds, by M. Berthelot. The experiments show that the action (sufficiently intense and prolonged) of hydriodic acid brings all these carburets to the composition of carburets absolutely saturated, such as hydride of hexylene, $C_{12}H_{14}$, volatile about 69°.—Reply to a recent note of M. de Parville, "On the semi-diurnal variation of the barometer," by M. Faye.—The echidna of New Guinea, by M. Gervais. This animal is very different from the echidna of Australia. *Inter alia*, it is larger and has darker hair; the claws (which are strong and adapted for digging) number three on the fore as on the hind feet; and the (black) muzzle is much longer than in *E. aculeata*, and sensibly arched; the tongue is also much longer and very slender, and the horny papillæ are differently arranged; the number of vertebræ and ribs is different, &c. M. Gervais regards the animal as belonging to a separate genus, termed *Acanthoglossus*.—On a project of an inter-oceanic canal; studies of the international commission of the Isthmus of Darien, by M. de Lesseps. This relates to a report of recent scientific exploration by Lieut. Wyse (of the French Navy). The project comprises a tunnel of about 17 kilometres, the remainder of the length being about 55 kilometres. The total cost is estimated at 600,000,000 francs.—Stellar systems formed of stars associated in a common and rapid proper motion, by M. Flammarion.—On the order (or class) of a plane algebraic curve, of which each point (or each tangent) depends on a corresponding point of another plane curve and on the tangent at that point, by M. Fouret.—Applications of a mode of plane representation of classes of ruled surfaces, by M. Mannheim.—On the liquefaction of acetylene, by M. Cailletet. The gas was compressed by means of a hydraulic pump through mercury, in an apparatus of special form. Acetylene is liquefied, *e.g.*, at + 1° under 48 atm., at 18° under 83 atm., at 37° under 103 atm. The liquid is colourless and extremely mobile; it seems very refringent, and is lighter than water, in which it can be largely dissolved. It dissolves paraffin and fatty matters. Hydride of ethylene was liquefied in the apparatus at a slightly higher pressure than that of acetylene. The tensions of these two carburets and ethylene are but little different about zero. Reaction of chlorhydric acid on two isomeric butylenes and on olefines in general, by M. Le Bel. The ethylenic carburets combine with cold chlorhydric acid; on the contrary, the hydrocarbons $CH_2 = CHR$ and probably those with the formula $CHR = CHR'$ are not attacked.—On the alteration of eggs produced by mould from without, by MM. Béchamp and Eustache. Hen's eggs may remain long in a medium filled with infusoria without these organisms penetrating. The shell and its lining membrane can be traversed by mucedineæ, which develop abundantly on the inner face of the latter. The yolk-membrane, however, is impenetrable by mucedineæ or any other microzoa or microphytes. The mediate relations of mucedineæ with the yolk produce a true fermentation apart from any organic ferment except microzymas. The acidification of the white is due exclusively to the mycelium of the mould. The production of bacteria in the yolk is due to development of the normal microzymas of the yolk.—On a new function of the genital glands of sea-urchins, by M. Giard. During part of the year these glands play the part both of excretory organs and of deutoplasmigenic organs. This fact presents a new point of relation between echinoderms and annelids, and even arthropods.—Causes which determine the liberation of agile bodies (zoospores, antherozoids) in the lower plants, by M. Cornu. The exit is not the result simply of a physical phenomenon of endosmose, but is at least partly due to the activity of the corpuscles themselves. This activity requires a sufficient temperature, or a certain quantity of oxygen (furnished directly or by oxidation of the green parts), for its exercise.—Meteorological observations made in a balloon, by M. Terrier. This ascent was made on October 18, at 3.30 P.M., from Paris. It is affirmed that the temperature of the atmospheric layers at sunset decreases uniformly with increase of height (the decrease was 1° per 100 metres). The lower winds are less stable than the upper, and it is necessary to interpret the latter for weather prognostication. The aerial currents of small height and velocity are influenced and notably deflected by the inequalities of the ground.

DANISH GREENLAND

Danish Greenland; its People and its Products. By Dr. Henry Rink. Edited by Dr. Robert Brown, F.L.S. With Illustrations by the Eskimo and a Map. (London: Henry S. King and Co., 1877.)

THERE is a strange fascination about Greenland, which may be partly owing to the mystery that shrouds its early history,—partly to its being an almost Arctic country, the scanty population of which seems to furnish an example of a nation in the enjoyment of a very primitive culture; and partly because it seems very probable that it was from it started the voyagers who were the first discoverers of what is now called America.

Our knowledge of the early history of Greenland is limited to what we can gather from the Icelandic sagas or popular tales, and from these we find that about the year 986 an Icelander called Erik the Red, who had been outlawed, sailed to the west to look for some land which had some years previously been sighted by Gunbjörn, the son of Ulf Kraku, another Icelander who had once been driven far westward by a very fierce storm. Erik found the land, made a two winters' stay thereon, giving names to many places, and returning to Iceland called this new country Greenland, because, said he, people would sooner be induced to go thither in case it had a good name.

This first colonisation of Greenland seems at the time to have been fairly successful, and several ruins are still to be found which throw a light on the habits of these seafaring people. The present Eskimo station, Igaliko, situated on an isthmus between two fjords, is thought to have been the ancient residence of Erik. One of Erik's friends, named Herjulf, had a son called Bjarni, a promising youth, and very fond of travelling abroad. One year he would spend in Iceland, another with his father in Greenland. Wishing, however, to spend one Yule-tide with his father, he set sail for Greenland, where his father was, with a crew who had never been in the Greenland Ocean before, and the consequence seems to have been that he found himself after many days near a country covered with wood, which was certainly not Greenland, and turning his back upon it to hasten to find his parent, he succeeded in landing at the very spot where his father lived. It is probable that during this voyage he had discovered the tract of country stretching from Connecticut to Newfoundland.

The news of Bjarni's venturesome voyage spread to Iceland and to Norway, and Leif, the son of Erik the Red, bought his ship, and set sail for the new country, on which they landed, and which, from finding on it a species of "fox-grapes," they called Vinland. Returning the next year to Greenland, it was no wonder that Vinland was all the talk, and Thorvald, about 1002, went to settle there and finally had a battle with the natives, in which he was killed. This Vinland was probably the present Massachusetts. Half a century later tidings from the Greenland colonies suddenly became rare, but in 1126 the then pope sent them a bishop, the ruins of whose church are still pointed out, and about 1261 the Greenlanders became subjects of Norway. From this date to 1450 tidings of the colonists, stories of their doings, and records of their misfortunes, came less and less frequently to Europe. The very sailing route passed into oblivion, and the country was only again re-discovered in 1585 by John Davis, whose name will be for ever remembered in connection with the Straits also discovered by him. Another century-and-a-half passed away before the present European stations in Greenland were founded by the well-known Danish missionary, Hans Egede, who in 1721 landed on an island at the mouth of the Godthaab-fjord and founded a regular colony. From then until now, with many a vicissitude; an epidemic of small-pox in 1734, a total interruption with Denmark (1807–1814) on account of the war; the colonies have struggled on. The trade was for some part of the former century made a private monopoly, but in order to keep up the commerce, the government was finally obliged to take it in hand, and since 1774 it has continued to be a royal monopoly. Following the steps of the extending trade, the missionary institutions have gradually incorporated the whole population into Christian communities.

Dr. Rink's book tells us in a very succinct though most interesting manner, of the results of the European transactions thus carried on in Greenland, for now over a century, and he describes the present state, and hints at the future prospects of the population. More than this, he gives us in well-written chapters, an account of the configuration and general physical features of this almost frozen up island, he tells of its "inland ice," and of the origin of the "floating icebergs." We read of the temperature, prevailing winds, the wonderful changeableness of its weather, and we find here a *résumé* of all that is known about its lakes and streams, its mysterious fjords, and of its great fields of drifting ice. Nor is the natural history of the country overlooked, for we have a chapter on its geological and mineral products. Of these latter cyolite appears to be the only one that has become a regular article of trade, about 10,000 tons thereof being exported each year. There are also chapters on its plants and animals, with special ones on the capture of whales and seals, and on the Greenland fisheries.

From an Eskimo point of view the commercial importance of the seal and whale fisheries is very great. The flesh and blubber of these animals not only supply the Greenlander with nutritious food, but also provide him with heat and light. The sealskins too afford material for clothes, boats, and tents, and whaleskin called "matak," yields a favourite article of diet. It may give some idea of the vast numbers of these animals killed yearly to summarise the average annual catch as follows: Of *Phoca fœtida*, 51,000; of *P. vitulina*, 2,000; of *P. groenlandica*, 33,000; of *P. barbata*, 1,000; of *Cystophora cristata*, 3,000; and of narwhals, white whales, and walruses nearly 1,000. The right whale has nearly disappeared and the mean annual catch of the "humpback" whale is scarcely over two.

The most important fisheries in addition appear to be those of the cod fish, the halibut, and the capelin.

Perhaps there was not much to be said about the manners and customs of the people in the olden time; the change in religion seems to have very early modified the social condition of the people, and this portion of Dr.

Rink's book is the one that satisfied our curiosity the least. The sketches of Greenland life by natives, as translated from the "Greenland Journal," are interesting, but they tell us of very little except marvellous escapes from snowstorms and icebergs. The great endurance of suffering, as detailed in some of these stories, demonstrates that heroes can be found even in Greenland; the sublime spirit of martyrdom seems to breathe in the account of the "Kayakers cast ashore in a snowstorm."

Scattered through this volume are some sixteen plates, representing Greenland ways of life. These are exact copies of partially coloured drawings executed by natives entirely after their own ideas. The greater number are the work of a seal-hunter living in Kangek, who, falling sick, could not leave his bed. With the drawing which forms plate 16, he wrote to say that increasing illness prevented him from doing more, and he ended the letter with "from exhaustion I must cut my letter short, this too will be my future fate," and shortly after he died.

E. P. W.

OUR BOOK SHELF

A Sketch of the Geology of Leicestershire and Rutland. By W. J. Harrison. (Sheffield: W. White.)

THIS is a creditable compendium of what is known regarding the geology of the two countries of which it treats. It was originally prepared by its author for White's "History and Gazetteer of the Counties," and has been reprinted in a separate form. It can be had embellished with twelve photographs of various parts of the crystalline nucleus of Leicestershire. These are not particularly successful. Mr. Harrison has done well to put the best of them as a frontispiece. It represents the "coarse ashy slates" of Charnwood Forest. As a local guide this book may no doubt be useful; fuller information can be found in the works which Mr. Harrison cites, and especially in the maps and memoirs of the Geological Survey.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.]

Expected High Tides

IF I may judge from the note published in your issue of November 8 (p. 38), and Mr. Jenkins' letter in the last number of NATURE (p. 45), it would appear that the general public are unaware of publications which contain information respecting high tides.

The Admiralty tide tables contain the time and height of every tide in the year for twenty-four of the principal ports of the United Kingdom. There are also numerous other tide tables published, which give the *heights* as well as the *times* of high water. Amongst these may be mentioned Holden's Liverpool tables, which contain, besides Liverpool, eight other ports (London included), and at Liverpool are held in higher estimation than the Admiralty tables, inasmuch as Holden's predictions take into account the effect of the diurnal inequality at Liverpool, which heretofore has been neglected in the Admiralty tables. There are also published at South Shields, Ainsley's, and at Hartlepool, Pearson's tables, and at Bristol, Arrowsmith's tables (formerly Bunt's), which have deservedly a high reputatation for Bristol and the Bristol Channel ports generally.

Any one who will select from these publications the highest perigean spring tides about the time of the equinoxes, and will send them to the papers, can apparently earn for himself the credit of "predicting" high tides.

The increased range of tide in the Thames of about twenty inches during the last twenty years, is undoubtedly due, among other improvements, to the construction of the embankments, the increased water-way at the bridges at Westminster, and notably at Blackfriars, the improved line of wharfage continually being carried out, and the removal from the Pool of the colliers, which at low water acted as a dam, and prevented the improvement of the bed of the river.

An overflow in the Thames at above-average spring-tides is now a matter of meteorological circumstances only. It has been observed, I believe, without exception that the overflows have been caused by a strong northerly wind; the most disastrous overflows, however, have followed a strong south-west wind, changing suddenly to a stiff north-west wind. The reason is obvious. An increased amount of tidal water with a south west wind and generally low barometer, is carried from the Atlantic to the northern parts of the North Sea, a sudden change in the wind to north-west brings the whole of this water to the southward, with probably little or no disastrous effects until it reaches the mouth of the Thames, where it meets with the tidal water of the English Channel brought through the Straits of Dover. It then rushes up the Thames, and an additional height is given to the water, amounting sometimes to as much as four feet or more if there is much flood water meeting it, and an overflow is the consequence. I find the effect of a south-west wind on the tide in the Thames, as traced on a self-registering tide-gauge I have placed at Greenwich pier, is to depress the water considerably. The high water of Monday morning succeeding the heavy gale of Sunday, November 11, was nearly two feet below the predicted height, the extreme pressure of wind, as registered at the Royal Observatory, being 31 lbs. on the square foot. In the middle of October the effect of a south-west gale was still greater, probably owing to its longer continuance, although the registered pressure did not exceed 23 lbs. No overflow need therefore be feared from a continued south-west gale.

Mr. Jenkins is perhaps unaware that Mr. Saxby has "predicted" high tides for many years, and that on one occasion, I believe in September or October, 1869, the Astronomer-Royal wrote reassuring the public that there was nothing extraordinary in the then forthcoming spring tides to occasion unnecessary alarm. If Mr. Saxby has discovered some law by which he can foretell the direction and force of the wind he will undoubtedly confer an inestimable boon by its publication, but from the following extract from the *Times* of November 5 he does not appear to claim any such knowledge:—"Capt. Saxby further states: 'If the wind should blow from a northerly quarter on either the 7th of November or 22nd of December next, very full tides may be reasonably expected.'" The spring tides about December 22 are slightly below average, and as no overflow has yet occurred with below-average spring tides, but little apprehension need be felt respecting them.

With respect to the actions of Venus and Jupiter; although theoretically they cause tides, the values have hitherto not been evaluated, being almost insensible.

The high tide of October 26th was entirely due to the northerly wind; the effect due to the maximum northern declination of the moon is very small in the Thames, and is more than counterbalanced by its effect in decreasing the value of the lunar semidiurnal tide.

Mr. Jenkins' statement respecting two great tides revolving through the year exactly six-and-a-half synodic months apart is merely on account of thirteen semilunations being very nearly equal to seven anomalistic months, and therefore the lunar perigee has again the same phase with respect to new or full moon. I may mention that ninety-nine semilunations exceed four years by about eighteen hours only, and also fifty-three anomalistic months by less than thirty-three hours. So that after a cycle of four years the perigean spring-tides fall very nearly on the same days of the year. This of course fails to take into account the variations due to the moon's declination.

The following table of the heights of the above-average spring-tides for London for next year may be useful not only to riverside owners and dwellers, but also to marine naturalists, who will on these days have unusually favourable opportunities at low-water of engaging in their pursuits. If at such times the barometer should be high the low-water level will be still further depressed. It will also act as a guide to tourists wishing to avail themselves of the best chances of witnessing the bore in rivers, notably on the Severn, which, according to Mr. Alfred Tylor, F.G.S., is seen to best advantage with a rising sun from Stonebench Inn, about three miles below Gloucester.

From the above table it appears that the highest tides of the year will occur on March 20-21 and September 28. The heights will be found probably to exceed those of the Admiralty Tables, as I have employed larger factors in the necessary corrections to the semi-menstrual inequality.

As a London tide table appears to be a desideratum, I have been induced to publish one for next year, in which the "danger" tides will be distinguished in a new, bold, and unmistakable manner.

EDWARD ROBERTS

3, Verulam Buildings, Gray's Inn, November 17

Rainfall in the Temperate Zone in Connection with the Sun-spot Cycle

THIS month's number of the *Nineteenth Century* contains an article on the connection of rainfall with the eleven years' cycle of sun-spots. It takes a carefully-selected area in which such a coincidence, if it existed, would be well marked. The great tract of water spreading southwards from Asia to the southern pole affords an arena for the undisturbed play of solar activity. It may readily be understood that any excess of solar energy has a more direct and uniform influence upon the rainfall gathered from this vast aqueous expanse, than it would have upon smaller areas of water intermingled with tracts of land, and cut off from each other by ranges of mountains, as in the European and American continents. Other reasons exist which would render solar influence a more directly potent factor in the rainfall gathered from the Indian Ocean than in that of the temperate zone. Without doing more than alluding to the fact that sun-spot activity is confined to a belt of considerable thickness on either side of the sun's equator, there are several well-ascertained causes which would render an excess of solar activity more directly felt in the equatorial regions of our earth than in those nearer the poles. While, therefore, I believe that the coincidence of a rain cycle and of a cycle of wind disturbances with the eleven years' cycle of sun-spots, has now been established as regards the Indian Ocean and the Madras rainfall, I am anxious to guard against the conclusion being pushed too far. The article in the *Nineteenth Century* proves much, but it would be a misfortune at this still early stage of the inquiry, if wider inductions were drawn from it than are justified by the evidence which it brings forward.

It seems right, therefore, to state that so far as my investigation of the rain returns of the temperate zone yet enables me to form an opinion, the cyclic coincidence of the rainfall with the eleven years' cycle of sun-spots, seems to shade off in extra-tropical regions until it ceases to exist at all. This opinion is based upon an examination of the returns of between one and two hundred stations in different parts of the world, but only with regard to one-third of them is the evidence sufficiently complete as to raise more than a presumption either for or against the existence of a cycle. Further, I have not yet been able, except in comparatively small groups of stations, to examine the monthly returns or to separate the winter from the summer rainfall. This separation forms one of the first essentials to arriving at a final opinion on the question. Subject to these remarks, I beg to state the facts with regard to the rainfall of the northern extra-tropical zone in India, Europe, and America. It is chiefly with the first and last-named countries that the present contribution will deal.

In my "Cycle of Drought and Famine," printed in India on the commencement of the late dearth, I mentioned that the rainfall which, in periods of minimum sun-spots, passes uncondensed over the Southern Presidency, might possibly "fall in the temperate zone. The excessive rain, if it takes place anywhere, will probably be found in India between the 22nd and 32nd degree of north latitude, to the south of the great Himalayan partition wall." The conjecture was based upon the configuration of the Indian continent, which, in its lower and middle regions, receives the rainfall gathered from a vast ocean, and is provided with a barrier at the upper end to arrest the rain-clouds on their further progress northward. Prof. Archibald's examination of the rainfall in Northern India now throws a clear light on this side of the question. He has published in the leading Calcutta paper, the *Englishman*, a series of carefully-compiled returns from stations within the ten degrees of latitude above mentioned. He shows that the rainfall of the sub-tropical region, from 22° to, say, 30°, is in some respects (but only in some respects) complementary to the rainfall of Southern India, and in a recent letter to me he thus summarises his conclusions:—First, the winter-rainfall of Northern India varies inversely with the sun-spots in a well-marked manner at all the stations. Second, the summer rainfall varies directly with the sun-spots, in a manner well marked in the north-western provinces, by no means marked in the lower provinces of Bengal, but sufficiently well marked when the returns of the several stations are combined.

Let us examine the meaning of these facts. The returns from Madras and Bombay (lately published in NATURE and elsewhere) prove that when the summer monsoon strikes Southern India, its aqueous burden varies directly with the sun-spots. Prof. Archibald's returns now show that the rainfall brought by the summer monsoon to Northern India also varies directly with the sun-spots. But they prove more than this. They show that the rain-clouds which, in years of minimum sun-spots pass over India without dropping their watery burden, are found, on their being stopped by the Himalayan partition wall, to be charged with a more than average surplus (so to speak) of moisture. In Northern India, therefore, the summer monsoon, on its passage up, brings, as in Southern India, a rainfall varying directly with sun-spot activity; but the winter rainfall, *i.e.*, the immediate rebound of the rain-clouds from the Himalayan barrier, varies inversely with sun-spot activity. I say the immediate rebound, for it must not be forgotten that the north-eastern monsoon (October to December), when it strikes Madras in its full development, after collecting its aqueous freight from the Bay of Bengal, follows the same law as the summer monsoon (May to September), and varies directly with the sun-spots.

Passing from the sub-tropical region of Northern India (22° to 32° lat.) to the temperate zone, we find the evidence of a cycle either very faint or altogether wanting. With regard to Europe, I am not yet prepared to offer any new facts. The existing evidence only amounts to this: (1) Mr. Baxendell, from observations for a comparatively short period but very carefully recorded and scrutinised, came to the conclusion that even at an English station, notwithstanding the manifold disturbing influences incident to our insular meteorology, changes take place in the rainfall as well as in the temperature and barometric pressure, which correspond closely in their maxima and minima periods with those of sun-spots. (2) A more comprehensive survey of the European rainfall has so far failed to establish this correspondence. Dr. Jelinek's examination of fourteen stations, from 1833 to 1869, showed that the coincidence held good in fifty-two cases, but failed in forty-two. While frankly accepting this as evidence against a real coincidence, it should be remembered that a general law such as a common periodicity in sun-spot activity and terrestrial rainfall will be subjected to, and sometimes overruled by, the local surroundings of individual stations. (3) On the other side, Gustav Wex, from the recorded depths of the Elbe, Rhine, Oder, Danube, and Vistula, for six sun-spot cycles (1800–1867), found that the maximum amount of water occurred during periods of maximum sun-spots, while the minimum levels were reached in the periods of minimum sun-spots. The evidence, as regards Europe, is, therefore, conflicting; and it is safer for the present to reckon it as against a well-marked common periodicity. I hope at no distant date to submit the results of a new and more exhaustive examination of the European rain-registers.

I now proceed to the North American rainfall. Here, as in Europe, the question is complicated not merely by disturbing meteorological influences, such as the Gulf Stream, but by the uncertain value of the rain-returns. These are causes which even at a carefully supervised station render it difficult to estimate the number of inches yielded by long-continued or very violent snow-storms. At badly supervised stations, or in the case of private gauges where the supervision is apt to be of a still more hap-hazard character, these difficulties often suffice to render the returns quite worthless. Yet it is the latter class of records on which we have chiefly to depend in an attempt to deal with the American rainfall during a long series of years. Nowhere does meteorology now receive more careful and scientific study than in the Western Continent, but in many of the most valuable series the element of time is still necessarily wanting. The evidence hitherto received from America has, on the whole, been favourable to the existence of a common periodicity. Mr. Dawson, Geologist to the British North American Boundary Commission, found a correspondence, although by no means an absolute one, between the fluctuations of the great lakes and the sun-spot periods. This question has been lately revived and interpreted afresh by a distinguished meteorological observer in Northern India. Prof. Brocklesby's contributions to the *American Journal of Science* also point to a connection between variations in the sun-spot area and annual rainfall.

It was with a knowledge of these statements that I undertook a systematic inquiry into the American rain-returns. I ought at once to say that the result of that inquiry altogether fails to establish the existence of a common cycle, so far as concerns the temperate zone. I divided the American stations into four groups. The first group consisted of eleven stations in east coast or Atlantic States, lying between 40° and 45° N. latitude. The second group consisted of seven stations in Inland States, from 38° to 48°. The third group was intended to consist of stations in the West Coast or Pacific States, but I have obtained the returns (and those for a period altogether too brief) for only a single West Coast Station, San Francisco. I give them, however, for what they are worth. The fourth group consists of three coast-stations in the Southern States, between 30° and 33°; or just above the sub-tropical region with which Mr Archibald's returns for the Bengal stations deal.

The results of the examination of the four American groups may be summarised thus: (1) Taken as a whole, the returns from the twenty-two stations do not exhibit any common periodicity between the rainfall and the sun-spots; nor do they disclose an eleven year's cycle corresponding to the one which I have shown to exist in the rainfall (at Madras and elsewhere) gathered from the Indian Ocean. (2) That as regards the three northern groups, stretching across the continent from 38° to 48° N. lat., the rainfall, so far as any symptoms of periodicity can be detected at all, tends to vary inversely with the sun-spots; but that it is impossible to discover any real periodicity whatever. (3) On the other hand, that as regards the southern group, between 30° and 33°, there are symptoms of a periodicity tending to coincide with the sun-spot variations; but that these symptoms are not sufficiently uniform in the small number of southern stations which I have examined, to justify any conclusion.

The calculations on which these results are based would occupy many pages, but their general line may be indicated in a few sentences. Thus the mean rainfall at the twenty-two stations during the years of *maximum* sun-spots for which the records have been obtained, was 37½ inches, while during the years of minimum sun-spots it was 39. The years of maximum sun-spots, together with the years immediately preceding, had a mean fall at the twenty-two stations of 40·2 inches; while the minimum years of sun-spots, taken together with the years immediately preceding, had an almost exactly equal rainfall of 40·1 inches. In the northernmost group of eleven Atlantic stations the mean rainfall of the years of maximum sun-spots was 39 inches, against an average of 41 inches in years of minimum sun-spots; in the second group of seven inland stations (38° to 48°) the mean rainfall of the years of maximum sun-spots was precisely equal to that of years of minimum sun-spots, being 33¾ inches in both; in the third group, San Francisco, the mean rainfall years of maximum sun-spots was 21 inches against 23½ inches in minimum years; in the fourth group of three southern stations (30° to 33°) the returns for the minimum and maximum years are broken; but taking these years and the preceding ones together, the mean rainfall of the years of maximum sun-spots with the years immediately preceding was 51 inches, against 48½ inches in the years of minimum sun-spots and immediately preceding ones.

The returns have also been examined by another method. I have shown elsewhere that the rainfall at Madras, and other stations around the Indian Ocean, follows a well-marked cycle of eleven years, with a maximum, minimum, and intermediate period, corresponding with the maximum, minimum, and intermediate period of sun-spots. The American stations not only fail to show such a correspondence, but as regards the three northern groups so far as any symptoms of periodicity exist, they point in the opposite direction. The fourth or southern group of stations, on the other hand, so far as they disclose a periodicity, tend to coincide with the periodical variations in the sun-spots. The following table will show this. The Madras rainfall in the tropics discloses a cycle closely corresponding with the eleven cycle of sun-spots; speaking generally, the American rainfall in the temperate zone discloses no such cycle; but the southern stations begin to furnish symptoms of such a cycle.

Table of Madras and American Rainfall Compared with the Eleven Years' Cycle of Sun-spots

Rainfall and sun-spots shown in the minimum, intermediate, and maximum groups of the eleven years' cycle.	*Minimum Group.* Mean of 11th, 1st, and 2nd years.	*Intermediate Group.* Mean of 3rd, 4th, 9th, and 10th years.	*Maximum Group.* Mean of 5th, 6th, 7th, and 8th years.	Remarks.
Eleven years' cycle of sun-spots (from Wolf's lists)	12·6	43·5	76·8	Common Periodicity well marked.
Eleven years' cycle of rainfall at Madras	Inches. 40·3		Inches. 53·5	
Eleven years' cycle of rainfall; mean of three stations around the Indian Ocean...	43·4	48·1	52·2	
North American Rainfall.				
Mean of eleven stations in East Coast States, 40° to 45° N. lat....	40·2	41·6	40·1	No common Periodicity.
Mean of seven stations in Inland States, 38° to 48° N. lat.	35·3	35·8	34·6	
San Francisco; West Coast Station, 38° N lat		19·9	22·3	
Mean of three stations in Southern States, 30° to 33° N. lat.		51·2	49·1	Symptoms of common Periodicity.

NOTE.—The sun-spot figures represent the relative numbers, reduced from Wolf. The rainfall is expressed in inches. The San Francisco returns deal with only twenty-one years, or not quite two complete cycles; much too short a period for any definite conclusion.

The records of the twenty-two American stations extend over brief periods compared with the Madras returns. Several of them disclose breaks or gaps; few of them have been kept with the minute care bestowed by the professional astronomical staff on the rain gauge at the Madras Observatory, and the value of most of the eighteen northern ones is rendered in some degree uncertain by snow-storms. It is probable, moreover, that better and much more complete returns are available to American meteorologists than I possess for the twenty-two stations which

I have examined. They will come to the criticism of my results with fuller materials than are available to me here, but so far as these materials enable me to form an opinion, the result is against the existence of a common periodicity in the sun-spots and in the American rainfall within the temperate zone.

Allanton, Lanarkshire, November 4 W. W. HUNTER

Contribution to the Sun-spot Theory of Rainfall

THE Lucknow Meteorological Observatory has been established since 1868, and regular observations have been recorded since that year under my superintendence.

In NATURE of December 12, 1872, Mr. Lockyer published a notice of Mr. Meldrum's discovery of the coincidence between the maximum and minimum sun-spot periods, and the maximum and minimum rainfall in certain places. After reading it I examined the annual rainfall at Lucknow from 1868 to 1872, and found that there was reason to believe that the rainfall at Lucknow followed the same cycle as that of the sun-spots. The figures were:—

1868	27·6 inches.
1869	41·9 ,,
1870	64·6 ,,
1871	65·0 ,,
1872	41·4 ,,

The equal amount of rainfall (41 inches) on both sides of the maximum fall of 1870 and 1871 was very striking, and as there was a rise in the rainfall from 1868 to 1870–71, and after that a decrease, and having just read Meldrum's discovery, I conjectured that the annual rainfall would continue to decrease till it reached its minimum. In my annual abstract, which I submitted to Government in April, 1873, and on the slender evidence of five year's rainfall, I ventured to state that if Meldrum's law be true, we had in Lucknow lately passed the period of maximum rainfall, and were descending towards a minimum, so that during 1877, 1878, and 1879 there would be a scarcity of rain, and in one of those years the minimum rainfall of the cycle would occur. I am now able to give the annual rainfall of almost a complete cycle, and the figures will speak for themselves:—

1867 was a sun-spot minimum period.

1868	27·6	Inches of rainfall in Lucknow.
1869	41·9	
1870	64·6	
1871	65·0	
1872	41·4	
1873	35·1	
1874	51·4	
1875	43·5	
1876	23·6	
1877	11·7	

(Up to date October 22).

This is October 22, 1877, and the total fall up to date has been only 11·7 inches, about a third of which fell in the months of January, February, and March. The fall during the rainy season of 1877 has been so small that great fear of a famine has been felt. I considered Meldrum's discovery so important that at the end of my annual abstract of meteorological observations for 1872, I inserted a long abstract of Mr. Lockyer's article in NATURE, in order to make the theory more widely known.

I believe meteorologists are on the track of a most important law. I would not expect the maximum and minimum rainfalls in every place to coincide with the sun-spot maximum and minimum so completely as that given above. Possibly in some places the figures might be reversed, owing to a changed direction in the water-bearing currents of the atmosphere; but that the changes occurring in the sun have a direct influence on rainfall there cannot, I think, be any doubt. E. BONAVIA

Lucknow, October 22

The Radiometer and its Lessons

I WISH that Prof. G. C. Foster had been more explicit in his answer to my letter; for as it is I cannot understand to what "variations of density" he refers. So far as I know there are no variations of density in the gas in question except those which arise from variations of temperature; but these variations of density certainly do not affect the rate at which heat diffuses into and through the gas, for this rate is independent of the density and for the same gas depend only on the absolute temperature and on the degradation of temperature in the direction in which the diffusion takes place. The variations of temperature do affect the rate of communication but only in proportion to the square root of the absolute temperature, and hence, in the case of the radiometer, only to an inappreciable extent.

It is obvious that the law of diffusion holds good only so long as the gas is undisturbed by convection currents. Such currents, which certainly exist, increase the rate at which heat is communicated to the gas, that is to say, the hot surface instead of being exposed to the action of still air is exposed to a wind which tends to increase the rate of cooling. But the velocity of the wind does not increase with the rarefaction, and the cooling effect of a wind of a certain velocity does increase with the density of the air. Hence, as I pointed out in my first paper, the motion of the air will favour the force resulting from the communication of heat less and less as the rarefaction is increased.

As regards Mr. Johnstone Stoney's theory. The post which brought me this week's NATURE brought me also a paper from Mr. Stoney, on which I venture to comment. In doing this, however, I may say that I have no wish to criticise what Mr. Stoney has written. The fact that Mr. Stoney has in no way referred to my work, although I preceded him by some two years, has relieved me from all obligation to discuss Mr. Stoney's theory; and I certainly should not do so now were it not that, as Prof. Foster has instanced this theory as disproving what I believe to be the truth, I feel bound either to show wherein it is wrong or acknowledge my inability to do so.

In the paper which I have just received,[1] Mr. Stoney starts with an assumption that, but for the effect of gravitation, "a flat stratum of gas in contact with a hot surface, A," and "everywhere subject to the same pressure" can exist in a state of equilibrium "except at the limits," without any passage of heat from the hotter to the colder part, although "within the stratum the temperature gradually decreases, from within outwards, from θ_1 the temperature of A to θ_2 the temperature of the surrounding gas."

In support of this assumption I cannot find that any proof is offered except that which is contained in the following portion of a sentence:—"We know, from familiar experiments, which show gases to be bad conductors of heat, that after the brief interval of adjustment a permanent state would ensue in which there would be no further change of density, or motion of heat, except by radiation."

Now this assumption and the statement in support of it—in both of which Mr. Stoney seems to have ignored the very existence of diffusion of heat in gases—are contrary to all experience as well as to the deductions from the kinetic theory of gases; for it follows directly from the kinetic theory, and has been abundantly established by experiment, that under no circumstances can there exist a variation in the temperature of a continuous layer of gas without heat diffusing from the hotter to the cooler part.

I think that I need say no more. This assumed condition of gas forms the base of all Mr. Stoney's reasoning, and although in a subsequent part of his paper he appears to me to have arrived at deductions which contradict his fundamental assumption, still this assumption may be held accountable for the anomalies which he has found. OSBORNE REYNOLDS

November 17

I BEG to call the attention of the readers of NATURE to the following passage at the commencement of Mr. Crookes's lecture at the Royal Institution on February 11, 1876, "On the Mechanical Action of Light":—

"To generate motion has been found a characteristic common, with one exception, to all the phases of physical force." [Illustrations are then given of the production of motion by heat, magnetism, electricity, gravitation, sound, and chemical force.]

"But *light*, in some respects the highest of the powers of nature, *has not hitherto been found capable of direct conversion into motion;* and such an exception cannot but be regarded as a singular anomaly.

"This anomaly the researches which I am about to bring before you have now removed; and, like the other forms of force, *light is found to be capable of direct conversion into motion*, and of being most delicately and accurately measured by the amount of motion thus produced."

I cannot but suppose that Mr. Crookes and Prof. Carey Foster have alike forgotten the existence of this passage. If it does *not* convey an interpretation of the phenomena of the radiometer which is now admitted on all hands to be wrong, and imply a claim to the discovery of "a new mode of force," I am incapable of understanding the meaning of words.

I may add that one after another of my eminent scientific friends has assured me that I was perfectly justified in my statement on this point; and it was by one of these, who was present at the lecture in question, that I was informed of the very explicit statement made on that occasion by Mr. Crookes of the views he then held, which were universally understood in their plain common-sense meaning.

Fluid Films

WITH reference to Mr Sedley Taylor's interesting note on Fluid Films, allow me to say that if a drop of water, clinging to the outside of a glass goblet, be lightly dusted with lycopodium powder, and a fiddle-bow be drawn across the edge of the glass, the drop will exhibit vortices, rotating in opposite directions.

Highgate, N., November 19 C. TOMLINSON

Tuckey and Stanley.—The Yallala Rapids on the Congo

CAPT. TUCKEY is dead and gone and cannot answer for himself; it may therefore, perhaps, serve to clear his memory in some measure of a doubt about the correctness of his description of the Yallala Rapids in 1816, arising from the very different account of them given by Stanley sixty years afterwards, if I mention one of several facts in connection with American rivers.

The late Sir J. Franklin, in his first and disastrous overland journey to the Arctic Sea in 1821, describes the "Bloody Fall" on the Coppermine River as "a shelving cascade about *three hundred yards* in length, having a descent of ten or fifteen feet."

Between 1848 and 1851 this "fall" was visited five times; on one or other of such occasions the water was either at high spring flood, at low summer level, or at an intermediate elevation, yet under none of these conditions was the "fall" found to be more than *thirty yards long*, if so much, the height being about fifteen feet.

Franklin and the officers with him were most careful and correct observers, so that I can only attribute this wonderful change (from three hundred yards long to thirty) in the form of the cascade to the wearing away of the material forming the bed of the river, by the action of the water, assisted in a great measure by the large masses of ice and the stones carried down with it during the breaking up of the navigation in the course of thirty seasons, only half the interval of time between Tuckey's and Stanley's visits to the Congo.

Supposing a somewhat similar attrition, but in a less rapid manner, to have been going on at the Yallala Rapid, the description given by the former as he saw it may be equally correct as that of the latter when he visited it in its altered shape in 1877.

May I add that a cataract may become a fall or a series of falls, and *vice versâ*, according as the water in a river is in flood or at low level. J. RAE

Scientific Club, November 16

The Future of our British Flora

IT may interest Mr. Shaw to know that the stations given by Lightfoot in his "Flora Scotica, 1777," still exist (as far as I am aware, and I have visited by far the greater number of them) at the present day. Experience has led me to the conclusion that a plant however maltreated, does not become extinct unless the *natural conditions are changed*, as by the draining of a marsh, &c. I have over and over again found plants in stations where they were reported as "extinct years ago." Perhaps if Mr. Shaw visits his station for the "Lizard Orchis" (is this *Orchis hircina*, L.? if so it is, I fancy, new to Scotch botanists) in the course of a year or two he may find it in as large quantity as ever. As regards the maltreatment of plants, I agree with what Mr. Shaw says respecting professors of botany. Each teacher of the science ought to teach his students that it is a crime to exterminate a plant, and that they can best learn botany from the observation of the common plants of their district; there is great room for improvement in this respect.

While a student I was often disgusted by seeing rare plants torn up and then cast away as if they had been a handful of grass, or, worse still, put in the vasculum and forgotten till the next Saturday, when they were thrown away; and all this without a word of remonstrance from those who ought to have exercised authority, "that's villainous, and shows a most pitiful ambition in the man who uses it."

Provided we reform a little, I do not think that, judging of the future by the past we have any reason to expect a large decrease in the ranks of our native flora. I do not suppose any species given by Lightfoot 100 years ago has become extinct even in *his* stations, and on the other hand we have had a considerable number added to it since his time.

Edinburgh A. CRAIG-CHRISTIE

Selective Discrimination of Insects

IN continuation of the interesting observations of "S. B." on selective discrimination of insects in NATURE, vol. xvi. p. 522, permit me to send you the following notes from my journal, made in August last:—

"Watched by the roadside near Kew Bridge Station, several species of Hymenoptera, of the genus *Bombus* principally; one visited thirty flowers of *Lamium purpureum* in succession, passing over without notice all the other plants in flower on the same bank—species of *Convolvulus*, *Rubus*, *Solanum*. Two other species of *Bombus* and a *Pieris rapæ* also patronised the *Lamium*, seeking it out deep in the thicket, thrusting their probosces even into withered cups, although the *Rubus*' flowers were far more accessible and seemed much more attractive, being fresh and well-expanded.

"On the same bank several species of Diptera—*Syrphus* chiefly—were visiting the *Rubus*, ignoring the *Lamium*. On another bank, some distance removed from the first, I observed, however, that the diptera were visiting the *Lamium* (one species was very busy on the convolvulus, applying its proboscis to the external aspect of the anther) while the Hymenoptera, species of wasp, were giving their attention to the *Rubus*."

I am sorry not to be in a position to identify the species of Hymenoptera and Diptera, being unable to capture specimens of either. HENRY O. FORBES

Highgate, N.

The Earth-worm in Relation to the Fertility of the Soil

IN your number of the 8th instant there are some interesting remarks upon the habits, &c., of the common earth-worm. From frequent observations I fully concur with the remark that the worm does not consume living vegetation but only vegetable matter undergoing decomposition.

I am also rather inclined to the opinion that there are (or may be) two reasons for the drawing in to their holes dead leaves, &c., the one being, for use as food, and the other to protect the holes from a too plentiful supply of water.

In this same connection I may mention what I have not before seen mention of, namely, the little mounds of small gravel stones which the worms heap up around the entrance to their holes. These are very curious and may be partly to prevent the entrance of water; and also, as I think, partly for rubbing against the worm's slimy body, as fish do.

It is very remarkable the extent to which loose gravel-stones (some as large as a hazel-nut, and even larger) are removed from a gravel-walk from distances quite beyond a foot, leaving the walk pitted all over. I have never seen a worm in the act of moving these stones and it is difficult to imagine how it is done, but as it generally takes place in wet weather, it may probably be by an adhesion of the stone to the slimy body of the worm.

As regards fertilising effects, it would be interesting to know whether the earthy matter composing worm-casts had passed through the worm's body, as the writer supposes, for in that case it would probably have more fertilising properties than if consisting merely of the natural soil thrown up as by moles.

The remark by one of your correspondents as to his observation of a line of darker soil thrown up by worms from a substratum of ashes deposited a considerable time before, would almost make it appear that the mole-like action above referred to took place. The writer, however, repeats his conviction that the matter composing worm-casts has passed through its (the worm's) body.

31, Stockwell Park Road GEO. H. PHIPPS

Smell and Hearing in Moths

"J. C." seems to draw inferences that moths have not the power of smell but have that of hearing. I feel quite certain they possess the former, but am in doubt about the latter. For the purpose of catching moths I use a preparation of beer and sugar boiled together, to which (after boiling) is added a little spirit, placing rags several folds thick, saturated in the preparation, upon garden-seats, low branches of trees, &c. I have in one evening taken as many as thirty-six moths (including red-, yellow-, crimson-underwing, swordgrass, angleshade, &c., &c.). What has attracted them unless smell? or what generally leads them to their food?

With reference to the sound of the glass, is it not the quick motion of the hand which disturbs the moth? E. H. K.

Carnivorous Plants

PROF. SERRANO FATIGATI, of Ciudad Real (Spain), has made some investigations upon two insect-feeding plants which he found during his last excursion to the province of Cordova, and on the general peculiarities of viscous plants during their flowering. The first of these plants is *Ononis natrix*; it grows at Sierra Palacios. The second appears to be *Silene viscosa*, and was found on the hill which connects the village of Belmery with the station. The experiments made upon these plants prove that when alive they were both covered abundantly with a viscous fluid, which in *Silene* was still visible after the specimens had been dried for four months. Prof. Fatigati has observed in several instances that every insect which touches their surface, and remains adherent to them, dies in a very few minutes. Remains of animals in different stages of decomposition may be seen on the plants he possesses.

The microscopical study of these plants has enabled the structure of their secretory glands to be examined. The glands of the plant *Ononis* are at the extremity of hairs composed of cylindrical cells, and are ovoid and multicellular. The protoplasm of the cylindrical cells always forms a parietal coating to the cell-wall. The glands of the *Silene* are simply conical epidermical protuberances, and are divided into two cells at the close of their development.

Prof. Serrano Fatigati has observed that in these species and in *Cistus ladaniferus* the secretion of the viscous fluid increases during their period of flowering; he is studying this matter, in order to ascertain whether this circumstance bears any connection with the production of heat and carbonic acid possessed by plants during the flowering period. FRANCISCO GINEZ

Espar eros 9, Madrid

OUR ASTRONOMICAL COLUMN

MINOR PLANETS.—Mr. J. N, Stockwell, of Cleveland, Ohio, who has had much experience in calculations relating to the small planets, draws attention to a curious circumstance connected with the observations of Gerda, discovered by Prof. Peters at Clinton, N.Y., on July 31, 1872. It had been supposed that this planet was observed again in 1873, 1876, and 1877, but on forming equations of condition for the correction of the elements, Mr. Stockwell found that the observations of 1873 are quite irreconcilable with those of the other oppositions, or that some incompatible conditions had been introduced into the equations. "The discovery of these incompatible conditions," he writes, "has been the occasion of an unusual amount of trouble and annoyance, and will be the source of future mortification, should the explanation at which I have arrived ultimately prove to be erroneous." Mr. Stockwell's conclusion is this, that notwithstanding the planet observed from September 27 to November 12, 1873, was very near the computed place of Gerda, it was really another body that was observed in that year. To decide this point he calculated an orbit upon the observations of 1873, which it appears are very well adapted to furnish reliable results, and finds the following elements, placing the elements of Gerda, as perturbed to the same date, in juxtaposition for the sake of comparison. The epoch is 1873, November 7·0 M.T. at Washington, longitudes from M.Eq. 1873·0:—

	PLANET OF 1873.	GERDA.
	° ′ ″	° ′ ″
Mean long.	35 4 57	35 47 14
π	213 14 38	208 19 29
☊	178 53 9	178 56 40
	1 36 3	1 36 19
φ	1 58 40	2 0 51
μ	613″·6390	614″·3842

It will be seen that four of the elements of the planet of 1873 are almost identical with those of Gerda, while the lines of apsides differ about five degrees. The actual distance of the planets from each other on November 7 would be 0·0188 of the earth's mean distance from the sun. Mr. Stockwell adds, "if there are really two planets moving in orbits so extremely near together, it must happen in the course of time, unless the mean distances are exactly the same, that they will approach each other so closely that their mutual perturbations will cause them to unite and form a single planet."

A similar case of near coincidence between the orbits of two minor planets is that of Fides and Maia, to which attention was first directed we believe by M. Lespiault, of Bordeaux. In 1876 the elements were as follow:—

	FIDES.	MAIA.
Epoch	July 27·0 Berlin M.T.	Oct. 4·5 Berlin M.T.
	° ′ ″	° ′ ″
Mean long.	326 33 33	27 37 21
π	66 27 20	48 8 26
☊	8 15 15	8 17 1
ι	3 6 49	3 5 40
φ	10 11 21	10 4 31
μ	826″·4417	824″·6400

Here, however, the planets are much further from each other than in the case of Gerda and the planet of 1873.

At present Gerda and its companion will not be favourably placed for observation, but in the ensuing year no doubt an effort will be made to decide if there are really two bodies revolving in such near proximity to each other. Questions of much interest may arise if this should prove to be the case.

The discoveries of minor planets during the present year now stand as follow:—

No. 170, Myrrha,	January	10,	by Perrotin, at Toulouse.
171, Ophelia,	January	13,	by Borrelly, at Marseilles.
172, Baucis,	February	5,	
173, ...	August	2,	
174, ...	September	2,	by Watson, at Ann Arbor, U.S.
175, ...	October	14,	by Peters, at Clinton, U.S.
176, ...	November	5,	by Paul Henry, at Paris.
177, ...	November	6,	by Palisa, at Pola.
A planet, ...	November	12,	by Watson, at Ann Arbor.

We adopt Prof. Peters' name for No. 170, instead of the inappropriate one proposed in France.

THE COMET OF 1672.—Madler has pointed out a distant resemblance between the elements of the comet of 1672 calculated by Halley, and those of the comet of 1812, which has been found to have a period of revolution of about seventy years, and which therefore might have been in perihelion in the former year. The comet of 1672 was observed by Hevelius from March 6 to April 21, and also by Richer off the coast of Africa during his voyage to Cayenne, from March 15 to the end of the month, though he only described its position roughly. The observations of Hevelius are published in the rare volume of his "Machina Cœlestis" (of which, by the way, the British Museum possesses two copies), and we believe in the small special publication issued at Dantzig in the same year, and entitled, "J. Hevelii, Epistola de Cometâ, anni 1672, Gedani observato, ad Henricum Oldenburgium."

Halley's orbit gives for three dates of observation by Hevelius, adopting his corrected times, the following positions:

	G.M.T.	Right Ascension.	Declinatio
	h. m.	° ′	° ′
1672, March 6, at	15 39 ...	353 16 ...	34 57 N.
„ „ 15, at	7 44 ...	18 2 ..	37 25
„ „ 29, at	8 8 ...	52 21 ...	30 21 N.

Without attempting an accurate reduction of the Dantzic observations, it may be seen that they agree sufficiently well with the positions deduced from Halley's orbit to render it probable that his elements would not be so far changed by a calculation from the improved places as to bring them materially closer to those of the comet of

1812, the re-appearance of which is shortly expected. We have already mentioned that sweeping-ephemerides have been prepared by Herr Mahn, of Strasburg, and may be found in "Vierteljahrsschrift der Astronomischen Gesellschaft, 12 Jahrgang, 2 Heft."

MR. DARWIN AT CAMBRIDGE

AS we intimated last week, the honorary degree of LL.D. was conferred on Mr. Charles Darwin at Cambridge on Saturday. The occasion was in many ways remarkable, and suggestive of reflections that must occur to all, and which need not be put formally into words. The university seems to have been conscious of the honour Mr. Darwin was doing it, and seldom, it is said, was a more exciting scene seen in the senate-house. To appoint a special congregation of the senate for the transaction of no other business but the conferment of a solitary degree, although it be *honoris causâ*, is only resorted to in exceptional and important cases. The step taken by the university evidently has met with general approval to judge by the tone of the assembly in the senate-house on Saturday. The building was packed, and the inevitable pastime of the undergraduates assumed a form extremely appropriate, however questionable its taste may have been.

The appearance of Mr. Darwin entering the senate-house by a side door, with the Master of Christ's, of which College Mr. Darwin is a member, was the signal for a burst of applause which was evidently the result of genuine enthusiasm, and was certainly thoroughly hearty. At two o'clock the Vice-Chancellor took his seat on the raised dais, and the business of the day began. Standing side by side with Mr. Darwin in the centre of the senate-house, Mr. Sandys, the Public Orator, commenced the delivery of the customary Latin oration. Interruptions from the galleries occasionally interfered with the orator's efforts to make himself heard, but the pleasant manner of his delivery, combined with great tact and judgment, helped to quiet the undergraduates' "chaff," and assisted him materially in getting through his task.

We have been favoured with a copy of the Public Orator's address, which our readers will no doubt read with interest, both on account of the elegance of its Latin, and for its neat summary of Dr. Darwin's work; indeed, in its way, it is somewhat of a literary curiosity.

"ORATIO AB ORATORE PUBLICO HABITA CANTABRIGIAE DIE XVII° NOVEMBRIS A. S. MDCCCLXXVII

"DIGNISSIME domine, domine Procancellarie, et tota Academia :—

"Meministis Horatianum illud, 'fortes creantur fortibus'; vix igitur necesse est commemorare viri huius de rerum natura optime meriti patrem fuisse medicum egregium, avum poetam quoque insignem. 'Doctrina sed vim promovet insitam'; iuvat igitur recordari pueritiam huius fovisse scholam celeberrimam Salopiensem; adulescentiam aluisse non modo Caledonicas illas Athenas, sed in hac etiam Academia Miltoni nostri Collegium. Tanti in laudem alumni, nisi fallor, ipsa paterni fluminis nympha, non immemor hunc primum patefecisse insularum corallinarum originem, illa inquam Sabrina quae Miltoni in carmine vivit,

curalio nitida roseum caput exseret unda,

frontemque tam venerabilem sua praecinget corolla.

"Quanta cum voluptate accepimus insularum illarum circulos, sese e vadis sensim attollentes, quasi florum immortalium palmarumque victricium corona locos illos virides placidosque in Oceani campo designare, ubi priores insulae depressae et sepultae sunt. Quam facete describit, quo modo varios sensuum affectus exprimant indices illi vultus et ipsa tacitorum oculorum eloquentia; quo more apes, dum dulce illud nectar e flore delibant, quod continuandae floris stirpi utile sit, ipsae aliunde referant. Quam venuste explicat, quo modo captet Venus ipsa muscas; quali ex origine sint Veneris volucres, 'raucae, tua cura, palumbes'; quibus cantuum illecebris, quo splendore plumarum, concilientur volucrum amores. Quam familiariter, velut rex ille excellenti sapientia, de tot rebus disserit, quicquid volat, quicquid natat, quicquid serpit humi; quam varia eruditione disputat de fabuloso illo lepadum balanorumque marinorum genere, de montium igneorum miraculis, sed idem de gracili vitis pampino et lentis hederarum bracchiis in apricum enitentium; quanta liberalitate in patrocinium suum vindicat non modo 'aurea pavonum saecla,' sed etiam minus pulchram simiarum familiam. Qua de re quanquam poeta vetus dixit, 'simia quam similis nobis'; nobis tamen, viri Academici, cum oratore Romano, viro Academicae praesertim philosophiae dedito, gloriari licet, 'mores' esse 'in utroque dispares.'

"Illud certe extra omnem controversiam constat, pulchrum esse tantam rerum naturae varietatem contemplari, regiones remotas invisere, silvarum incaeduarum solitudinem penetrare, insularum prope ignotarum recessus perscrutari, varias denique animalium formas comparare inter se et distinguere; pulchrius, haec omnia accuratissime observata aliorum in usum voluptatemque litterarum mandare monumentis; omnium pulcherrimum, infinita talium rerum multitudine ad leges quam paucissimas revocata, ipsum fontem et originem omnium repetere. Quanta igitur laude vir hic dignus est, qui adhuc iuvenis, aliorum magis quam suo commodo, tot terras lustraverit, lustratas feliciter descripserit; qui maturiore aetate, tot generibus animantium et earum rerum quas terra gignit diligenter investigatis, illi praesertim legi constituendae operam dederit, qua docere conatus est, ita e perpetuo prope ad internecionem debellantium certamine aptissimam quamque novae stirpi propagandae speciem vivam victricemque superesse, ut tot species inter se diversae alia ex alia minutatim per immensam annorum seriem generari potuerint.

'Usus et impigrae simul experientia mentis
paulatim docuit pedetemtim progredientes.
sic unumquicquid paulatim protrahit aetas
in medium ratioque in luminis erigit oras.
namque alid ex alio clarescere et ordine debet
omnibus, ad summum donec venere cacumen.'

"Tu vero, qui leges naturae tam docte illustraveris, legum doctor nobis esto.

"Duco ad vos CAROLUM DARWIN."

The conclusion of this oration was greeted with loud applause, and the proceedings ended with the Vice-Chancellor conferring the degree on Mr. Darwin in the usual formal manner.

In the evening the anniversary dinner of the Cambridge Philosophical Society was given in the Hall of Clare College. The president of the Society, Prof. Liveing, occupied the chair, and among the visitors present were Professors Huxley, Ramsay, Tyndall, Parker, Burdon Sanderson, Drs. Günther, Wilks, Pye Smith, Mr. Francis Galton, &c. Prof. Ramsay proposed the toast of the University of Cambridge, and Prof. Huxley responded to that of Mr. Darwin, who was unable to be present. In his speech Prof. Huxley sarcastically spoke of the University as reserving its highest honour till all other distinctions had been heaped on Mr. Darwin, that its own chaplet might crown the whole, and not be covered up. Prof. Huxley spoke of Mr. Darwin as the foremost among men of science, with one exception, since the days of Aristotle.

A special meeting of the Philosophical Society is to be held next Monday in the combination room of Christ's College, to consider the best means of making a permanent memorial of Mr. Darwin in the University. Would not [illegible] Darwin Professorship of General Biology be a very suitable memorial?

INTERNATIONAL GEOLOGICAL CONGRESS

AT the late meeting of the American Association for the Advancement of Science at Nashville, Tenn., Dr. T. Sterry Hunt presented a report on the above subject, of which at the time we gave a brief note. The following extracts, which have been sent us, will no doubt be more satisfactory to geologists :—

"The committee to arrange for an International Geological Exhibition and Congress, to be held in Paris in 1878, was appointed by this Association at Buffalo in August, 1876, and consisted of Messrs. W. B. Rogers, James Hall, J. W. Dawson, J. S. Newberry, T. Sterry Hunt, R. Pumpelly, and C. H. Hitchcock, together with T. H. Huxley for England, O. Torrel for Sweden, and E. H. von Baumhauer for Holland. At a meeting of the committee at Buffalo on August 25, 1876, James Hall was chosen chairman, and T. Sterry Hunt secretary. It was then agreed to prepare a circular setting forth the plan of an International Geological Exhibition, which should form a part of the general exhibition to be held at Paris in 1878, and indicating a scheme for the organisation of the geological collections to be sent thereto by the nations taking a part in that exhibition, and moreover, proposing an International Geological Congress to be held at Paris.

"The circular in accordance with this plan was duly prepared, and printed in English, French, and German, and before the end of the year had been sent by the secretary to the principal scientific societies and academies, as well as to the workers in geology throughout the world. The response to this invitation has been most gratifying. The Geological Society of France has formally recognised the great importance of the objects proposed, and promised its hearty co-operation, while private letters from its president to the secretary of the committee, and from Prof. Hébert to Prof. Hall, give cordial assurances of the same kind. Spanish and Italian geologists have translated and published the circular in their respective languages, and have communicated to the secretary their hearty approval of the plan. Prof. Capellini has, in this connection, published an interesting correspondence, calling attention to the fact that in 1874 he had laid the project of a similar International Geological Congress, to be held in Italy, before the Italian Minister of Agriculture, Industry, and Commerce.

"The Geological Society of London and the Geological Survey of Great Britain have also formally signified their approval of our objects, and the co-operation of Norway, Sweden, Russia, and Austro-Hungary, is promised. It is to be regretted that Germany has declined to take a part in the International Exhibition of 1878, but we trust that this will not prevent her geologists from joining in the proposed Congress. The director of the Geological Survey of Japan promises to aid in our work, and we have the same assurance from Brazil, where the circular has been translated into Portuguese. Chili and Mexico have also responded, and promise an ample representation of their geology at Paris next year; while Canada, both through her Geological Survey and in the person of Dr. Dawson, will probably be represented there.

"The Government of the United States has as yet failed to accept the invitation of France to take a part in the Exhibition of 1878, so that American geologists are not certain that they will be able to participate in the International Geological Exhibition of 1878. We are, however, assured that the Government is very desirous to have our country duly represented at Paris ; and it is to be hoped that at the approaching extra session of the United States Congress, measures will be taken for accepting the French invitation, and appointing a commission, so that our people may secure a representation in Paris. I am assured, on all sides, that our geologists desire to contribute largely to the International Geological Exhibition, and even at this late day it will be possible to do much. In any event it is probable that several members of our committee will be present at the proposed Geological Congress. The precise date of this has not yet been fixed, though your secretary is now in correspondence with the Secretary of the Geological Society of France upon this point, and believes that with the co-operation of that body a time convenient to all will be agreed upon.

"It is recommended by the Standing Committee of the Association that, in addition to the names of Prof. J. P. Lesley, of Philadelphia, and Prof. A. C. Ramsay, director of the Geological Survey of Great Britain, already added to the International Committee, the presidents for the time being of the Geological Societies of France, London, Edinburgh, and Dublin, of Berlin, of Belgium, Italy, Spain, Portugal, and the Imperial Geological Institute of Vienna, be invited to form part of our Commission. T. STERRY HUNT

"Secretary of the International Committee."

Shortly after the presentation of the above report, the secretary received official notice that the Geological Society of France had, in co-operation with the above plan, appointed at Paris a local committee of organisation for the proposed Congress, constituted as follows : Hébert, President ; Tournouer and Albert Gaudry, Vice-Presidents ; Bioche, Treasurer ; Jannetaz, Secretary-General ; Delaire, Sauvage, Brocchi, and Velain, Secretaries ; with the following : Belgrand Bureau, de Chancourtois, G. Cotteau, Damour, Daubrée, Delafosse, Delesse, Descloizeaux, Desnoyers, Fouqué, V. Gervais, Gruner, De Lapparent, Mallard, Milne-Edwards, Pellat, Marquis de Roys and L. Vaillant, Members of the Committee.

A circular issued by this committee bearing date July 31, invites all those interested in geological, mineralogical, and palæontological studies to take part in the approaching congress, and to subscribe the sum of *twelve francs* each, which will give a card of admission to the Congress, and right to all the publications thereof. All those who intend to be present are at the same time invited to send, as soon as possible, a list of the questions which seem to them worthy of general discussion, as well as of the communications which they propose to make touching these questions. They are also invited to indicate the date which appears to them most convenient for the meeting of the Congress.

As regards an International Geological Exhibition, the Paris Committee of Organisation state that the difficulty of finding a suitable locality seems to them an obstacle in the way of realising this part of the programme. They hope, however, that there will be many special collections sent, and beg the exhibitors of such to give the committee due notice of these, in order that a special catalogue of them may be prepared.

The secretary of the International Committee desires, in this connection, to call attention to the fact that his circular did not contemplate the holding of an International Geological Exhibition apart from the universal exhibition, but, in the language of that circular, *the making as complete as possible the geological department of the universal exhibition.* It is certain that, as at all previous similar exhibitions, the different nations will contribute more or less of geological material, and it was conceived that such collections, extended and systematised in accordance with the plan set forth in the circular, would, while forming a part of the universal exhibition, without farther cost meet all the requirements of an International Geological Exhibition. To the accomplishment of this end it will only be necessary for the exhibitors of all nations to send a list of their geological contributions to the Local Committee of Organisation at Paris.

All correspondence relating to the Congress should be addressed to Dr. Jannetaz, Sécrétaire-général, rue des Grands Augustins, 7, Paris, France; and all moneys sent to Dr. Bioche, at the same address.

THE MODERN TELESCOPE

THE gain to astronomy from the discovery of the telescope has been twofold. We have first, the gain to physical astronomy from the magnification of objects, and secondly, the gain to astronomy of position from the magnification, so to speak, of *space*, which enables minute portions of it to be most accurately quantified.

Looking back, nothing is more curious in the history of astronomy than the rooted objection which Hevel and others showed to apply the telescope to the pointers and pinnules of the instruments used in their day; but doubtless we must look for the explanation of this not only in the accuracy to which observers had attained by the old method, but in the rude nature of the telescope itself in the early times, before the introduction of the micrometer; the modern accuracy has been arrived at step by step.

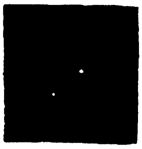

Fig. 1.—A portion of the constellation Gemini seen with the naked eye.

Let us see what the telescope does for us in the domain of that grand physical astronomy which deals with the number and appearances of the various bodies which people space.

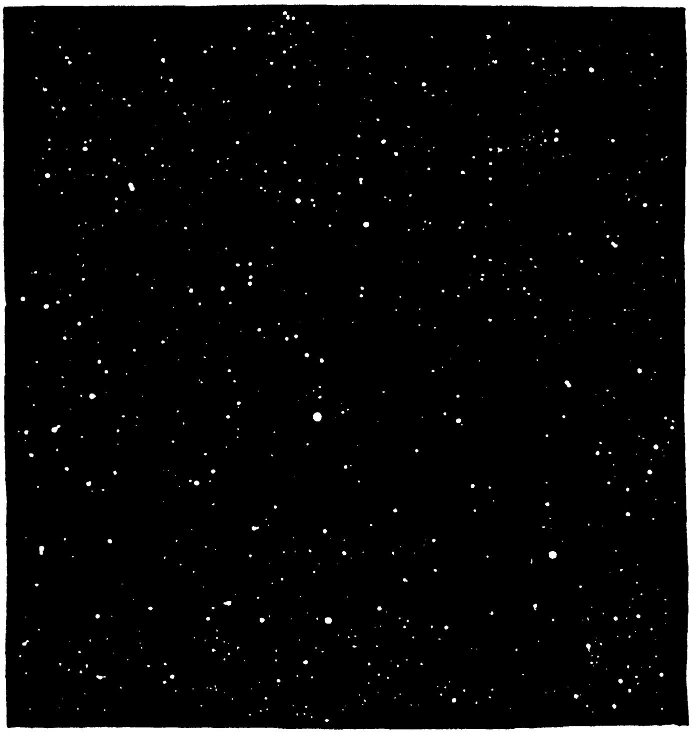

Fig. 2.—The same region, as seen through a large telescope.

Let us, to begin with, try to see how the telescope helps us in the matter of observations of the sun. The sun is about 90,000,000 of miles away; suppose, therefore, by means of a telescope reflecting or refracting, whichever we like, we use an eyepiece which will magnify say 900 times, we obviously bring the sun within 100,000 miles of us; that is to say, by means of this telescope, we can observe the sun with the naked eye as if it were within 100,000 miles of us. One may say, this is something, but not too much; it is only about half as far as the moon is from us. But when we recollect the enormous size of the sun, and that if the centre of the sun occupied the centre of our earth the circumference of the sun would extend considerably beyond the orbit of the moon, then one must acknowledge we have done something to bring the sun within half the distance of the moon. Suppose for looking at the moon we use on a telescope a power of 1,000, that is a power which magnifies 1,000 times, we shall bring the moon within 240 miles of us, and we shall be able to see the moon with a telescope of that magnifying power pretty much as if the moon were situated somewhere in Lancashire—Lancaster being about 240 miles from London.

It might appear at first sight possible in the case of all bodies to magnify the image formed by the object-glass to an unlimited extent by using a sufficiently powerful eye-piece. This, however, is not the case, for as an object is magnified it is spread over a larger portion of the retina than before; the brightness, therefore, becomes diminished as the area increases, and this takes place at a rate equal to the square of the increase in diameter. If, therefore, we require an object to be largely magnified we must produce an image sufficiently bright to bear such magnification; this means that we must use an object-glass or speculum of large diameter. Again, in observing a very faint object, such as a nebula or comet, we cannot, by decreasing the power of the eye-piece, increase the brightness to an unlimited extent, for as the power decreases, the focal length of the eye-piece also increases, and the eye-piece has to be larger, the emergent pencil is then larger than the pupil of the eye and consequently a portion of the rays of the cone from each point of the object is wasted.

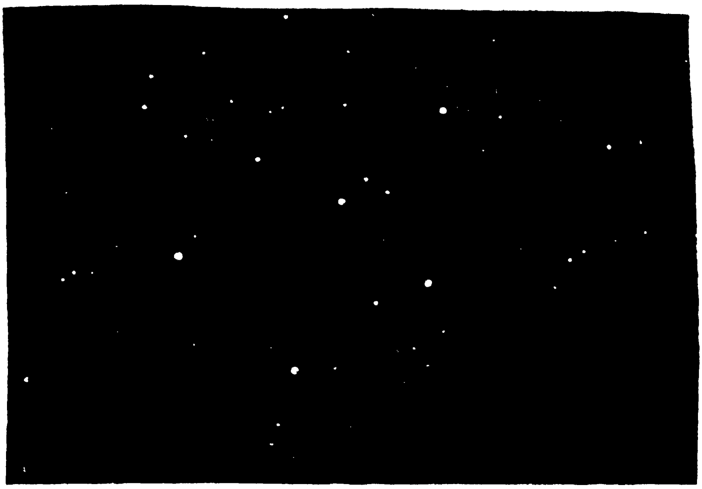

FIG 3 — Orion and the neighbouring constellations.

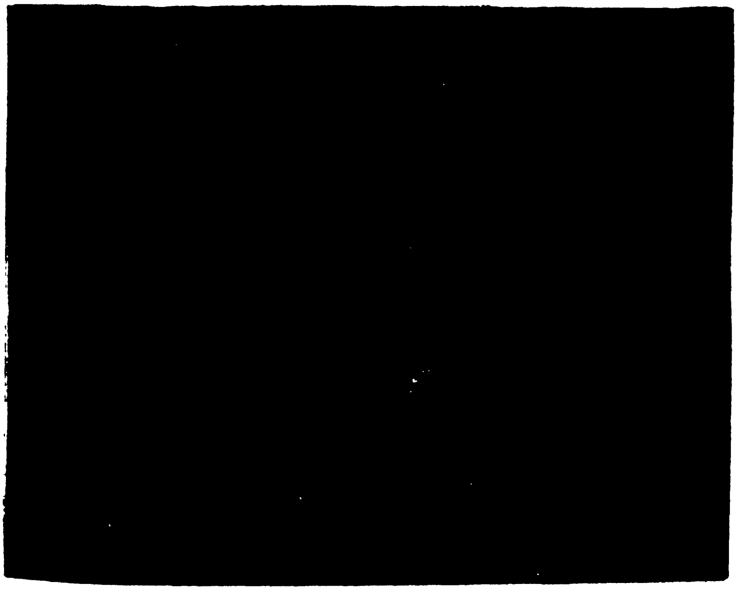

FIG. 4.—The Nebula of Orion, reduced from Lord Rosse's Drawing.

We get an immense gain to physical astronomy by the revelations of the fainter objects which, without the telescope, would have remained invisible to us; but, as we know, as each large telescope has exceeded preceding ones in illuminating power, the former bounds of the visible creation have been gradually extended, though even now we cannot be said to have got beyond certain small limits, for there are others beyond the region which the most powerful telescope reveals to us; though we have got only into the surface we have increased the 3,000 or 6,000 stars visible to the naked eye to something like twenty millions. This space-penetrating power of the telescope, as it is called, depends on the principle that whenever the image formed on the retina is less than sufficient to appear of an appreciable size the light is apparently spread out by a purely physiological action until the image, say of a star, appears of an appreciable diameter, and the effect on the retina of such small points of light is simply proportionate to the amount of light received, whether the eye be assisted by the telescope or not; the stars always, except when sufficiently bright to form diffraction rings, appearing of the same size. It therefore happens that as the apertures of telescopes increase, and with them the amount of light (the eye-pieces being sufficiently powerful to cause all the light to enter the eye), smaller and smaller stars become visible, while the larger stars appear to get brighter and brighter without increasing in size, the image of the brightest star with the highest power, if we neglect rays and diffraction rings, being really much smaller than the apparent size due to physiological effects, and of this latter size every star must appear.

The accompanying woodcuts of a region in the constellation of Gemini as seen with the naked eye and with a powerful telescope will give a better idea than mere language can do of the effect of this so-called space-penetrating power.

With nebulæ and comets matters are different, for these, even with small telescopes and low powers, often occupy an appreciable space on the retina. On increasing the aperture we must also increase the power of the eye-piece, in order that the more divergent cones of light from each point of the image shall enter the pupil, and therefore increase the area on the retina, over which the increased amount of light, due to greater aperture, is spread; the brightness, therefore, is not increased, unless indeed we were at the first using an unnecessary high power. On the other hand, if we lengthen the focus of the object-glass and increase its aperture the divergence of the cones of light is not increased and the eye-piece need not be altered, but the image at the focus of the object-glass is increased in size by the increase of focal length, and the image on the retina also increases as in the last case. We may therefore conclude that no comet or nebula of appreciable diameter, as seen through a telescope having an eye-piece of just such a focal length as to admit all the rays to the eye, can be made brighter by any increase of power, although it may easily be made to appear larger.

Very beautiful drawings of the nebula of Orion and of other nebulæ, as seen by Lord Rosse in his 6-foot reflector, and by the American astronomers with their 26-inch refractor, have been given to the world.

The magnificent nebula of Orion is scarcely visible to the naked eye; one can just see it glimmering on a fine night; but when a powerful telescope is used it is by far the most glorious object of its class in the northern hemisphere, and surpassed only by that surrounding the variable star η Argûs in the southern. And although, of course, the beauty and vastness of this stupendous and remote object increase with the increased power of the instrument brought to bear upon it, a large aperture is not needed to render it a most impressive and awe-inspiring object to the beholder. In an ordinary 5-foot achromatic many of its details are to be seen under favourable atmospheric conditions.

Those who are desirous of studying its appearance, as seen in the most powerful telescopes, are referred to the plate in Sir John Herschel's "Results of Astronomical Observations at the Cape of Good Hope," in which all its features are admirably delineated, and the positions of 150 stars which surround θ in the area occupied by the nebula laid down. In Fig. 4 it is represented in great detail, as seen with the included small stars, all of which have been mapped with reference to their positions and brightness. This, then, comes from that power of the telescope which simply makes it a sort of large eye. We may measure the illuminating power of the telescope by a reference to the size of our own eye. If one takes the pupil of an ordinary eye to be something like the fifth of an inch in diameter, which in some cases is an extreme estimate we shall find that its area would be roughly about one-thirtieth part of an inch. If we take Lord Rosse's speculum of six feet in diameter the area will be something like 4,000 inches; and if we multiply the two together we shall find, if we lose no light, we should get 120,000 times more light from Lord Rosse's telescope than we do from our unaided eye, everything supposed perfect.

Let us consider for a moment what this means; let us take a case in point. Suppose that owing to imperfections in reflection and other matters two-thirds of the light is lost so that the eye receives 40,000 times the amount given by the unaided vision, then a sixth magnitude star—a star just visible to the naked eye—would have 40,000 times more light, and it might be removed to a distance 200 times as great as it at present is and still be visible in the field of the telescope just as it at present is to the unaided eye. Can we judge how far off the stars are that are only just visible with Lord Rosse's instrument? Light travels at the rate of 185,000 miles a second, and from the nearest star it takes some 3½ years for light to reach us, and we shall be within bounds when we say that it will take light 300 years to reach us from many a sixth magnitude star.

But we may remove this star 200 times further away and yet see it with the telescope, so that we can probably see stars so far off that light takes 60,000 years to reach us, and when we gaze at the heavens at night we are viewing the stars not as they are at that moment, but as they were years or even hundreds of years ago, and when we call to our assistance the telescope the years become thousands and tens of thousands—expressed in miles these distances become too great for the imagination to grasp; yet we actually look into this vast abyss of space and see the laws of gravitation holding good there, and calculate the orbit of one star about another.

J. NORMAN LOCKYER

(*To be continued.*)

ZOOLOGICAL GARDENS[1]

THE lists and reports of the various zoological gardens now before us show that much progress has lately been made by these as by other institutions connected with natural history. For though zoological gardens are looked upon by many as a simple form of amusement there can be no question that, when rightly conducted, they are not only instructive in the highest degree, but also tend materially to advance the interests of the higher branches of natural science. All persons, therefore, who take an interest in the progress of science will be glad to see the number of zoological gardens increasing among the dependencies of this country and in other States.

Of the first of the five works on our list we need say but little. The Gardens of the Zoological Society of London, in the Regent's Park, are too well known to most of our readers to require a lengthened notice. The chief additions to their unrivalled menagerie are recorded every week in our columns. The volume now before us contains a catalogue of all the species of vertebrated animals, of which examples have been exhibited during the past fifteen years, arranged in systematic order. The various specimens are distinguished by letters, and the date and mode of acquisition of each individual are added. Thirty-five woodcuts, most of which have originally appeared in the Society's *Proceedings*, illustrate some of the more remarkable forms. The result shows that from the commencement of the year 1861 to the close of 1875, there have been obtained for the collection in the Regent's Park, examples of no less than 2,143 species of vertebrated animals. Of these 570 were mammals, 1,224 birds, 227 reptiles, 39 batrachians, and 83 fishes.

The catalogue of the animals in the newly-established Zoological Gardens at Calcutta, concerning the foundation and progress of which we have written at full length not long since,[2] is next upon our list. It is drawn up after

[2] NATURE, vol. xvi. p. 28.

AT the meeting of the Paris Academy of Sciences, on November 12, M. Faye presented the volume of the "Connaissance des Temps" for 1879. This publication has reached, according to M. Faye, the highest degree of perfection desirable, and the new volume is marked by two important improvements both due to M. Loewy. The first consists in a new method which enables longitudes to be calculated according to occultations of stars by the moon, and that with such facility that sailors will make use of them with great benefit. The second improvement consists in tables which enables the latitude to be obtained by observation of the polar.

THE death of von Baer has made a foreign associateship in the Paris Academy of Sciences vacant, and MM. Bertrand, Fizeau, Becquerel père, Claude Bernard, Dumas, and H. St. Claire Deville, have been appointed a commission to prepare a list of candidates for the vacant "fauteuil."

A PRIZE of 1,000 marks (50*l.*) is offered through Dr. Hermann J. Klein, of Cologne, for the best treatise on "The Development of Monistic Philosophy from Spinoza down to the Present Time." The treatise must be written in the German language, and must contain a complete account of the relation of Spinoza to the Cartesian philosophy, a description of the progress and changes in the monistic theory brought about by Leibniz, Schopenhauer, Lazarus Geiger, and Ludwig Noiré, and a clear definition of the differences between the materialistic and monistic theories. All details can be obtained from Dr. Klein. The term up to which treatises will be received is fixed for July 30, 1878.

BY a recent will, M. Maujean has bequeathed to the French Institute the capital producing a sum of 1,200 francs, designed to form a biennial prize of 2,000 francs, to be awarded alternately by the Académie Française, and by the Académie des Sciences. To obtain it of the latter, it is necessary to have published the work which shall be pronounced the most useful to hygiene, considered in all its branches.

THE Berlin Aquarium suffered, on November 13, the loss of what was certainly, from a scientific and from a financial standpoint, the most valuable zoological specimen in Europe, viz., the famous gorilla Pongo, whose human-like form and playful antics became so familiar to Londoners during the past summer. The visit to England, and stay in its warm moist climate, was regarded as having had the best effect on Pongo's health, when he returned to Berlin on September 21, and there was every prospect of the animal's being able to live through his second northern winter. Five weeks later, a lessening of appetite and slight diarrhœa were observed, but were not regarded by the physician as of sufficient importance to prevent Pongo's appearance in public. The consternation was great when a few days later, the gorilla died suddenly, without any apparent increase of dangerous symptoms. The loss to the Berlin Aquarium is no small one, as it had lately refused an offer of 2,500*l.* for the animal, and, taken in connection with the late deaths of their orang-outang and chimpanzee, will check somewhat the tendency to invest capital in anthropoidal apes. Not less severe is the loss to the scientific public, for no animal of late years has so attracted the attention of zoologists as Pongo, and theorists were looking forward with no slight degree of interest to the possibilities connected with his growth and education. After a dissection, which will probably reveal the cause of the sudden death, the skin will be handed over to the Berlin Anatomical Museum.

WE have received from Dr. Aguilar the annual volume of the Observatory of Madrid for the last year, 1876. It is a little late in the day, but we may call attention to the long and interesting article on geographical discovery with which the book terminates, seeing that that commences so early, "2400 (?) años A. des J. C. Dispersion de las gentes despues del Deluvio. Del cáos consiguiente á tan immensa catástrofe surgen á poco tiempo los tres grandes reinos de Babilonia, Ninive y Egipto."

ALREADY studied by two geologists, the Crimean peninsula has been recently visited by M. Ernest Favre, of Geneva. M. Hebert presented to the Paris Academy of Sciences, on Nov. 12, the results of this new examination, consisting of numerous sections on a very complete map.

HACHETTE and Co. are about to publish an important work of reference in Chemistry containing such important matter as the coefficients of dilatation, the specific weight of vapours, refrigerating mixtures, numerical documents on qualitative, quantitative, and spectral analysis, &c. We may state that the Smithsonian Institution are about to publish a similar work.

THERE are now "on view" at the Westminster Aquarium four Laplanders—two men and two women—who have with them reindeer, dogs, an Arctic fox, a tent, sledges, and numerous articles of dress of home manufacture. They have been brought to England by Mr. Carl Bock, through the enterprise of Mr. Farini, so well known as the "inventor" of Lulu's "upward bound," Zazel's "lightning flight," and Maraz's "eagle swoop." Any entertainment announced by one whose greatest successes hitherto have been to puzzle the public as to "how it is done" will naturally be looked upon with the same kind of suspicion that was bestowed on the "Egyptians" in the recent Lord Mayor's show. In some cases the public enjoys being puzzled, and this adds a zest to the enterprises of those who devise how to puzzle them. In the case of these Laplanders there does not appear to be the slightest ground for any suspicion as to genuineness. It will be recollected that Mr. Farini's whale at the aquarium was genuine, and when the *post-mortem* was held under the direction of Prof. Flower it was shown beyond doubt that it was not made of vulcanite and kept going by clock-work as was popularly supposed. We draw attention to the visit of these Laps because there is much of interest to be learnt from seeing them, and we do so with all the greater pleasure because the aquarium, looked at from a scientific point of view, has fallen from its high estate. We cannot pretend to make it a complaint that it is in the evening practically a large music hall with a miscellaneous entertainment by comic performers and sword swallowers. The place cannot be kept open without money, and if the public will not pay to go to an aquarium pure and simple, the management must provide what the public will take to, or shut up the place. But what we fear is that the management has been too much neglecting that part of the public, the minority certainly, who do care for an aquarium. Occasionally, especially during the control of Mr. Carrington, the aquarium has been in good order and well-stocked. It is again getting very unsatisfactory, perhaps because Mr. Carrington is in Naples. We gladly mentioned such recent improvements as throwing several tanks into one to make a place for large fish, and the removal of the seals to the whale tank, where their gambols in swimming can be better seen, and we have on several occasions recorded interesting arrivals, and if we could honestly do so we would gladly recommend the tanks generally as affording a good opportunity for studying the habits of the occupants. Though the Laps are not especially connected with aquarium objects the building affords a centrally located home for them. The performance, if it may be so called, through which they go, is an illustration of their quiet life, and happily there is no attempt to make it sensational. They show, among other things, how reindeer sinew is worked into a continuous thread, a process of interest to those who have examined collections from bone caves containing implements which it is believed were used either with such threads or strips of reindeer hide. The size of some of the eyes of the bone needles is more suggestive of thread than strips. Their monotonous singing on the syllables *wa wa wa*, if not

and a general feeling of regret is felt over his early death, away from home and friends. The French geologist, M. Largeau, is at present endeavouring to penetrate into the Tuarej region from the north, and the interest previously centred on von Bary's investigations will now gather about his efforts.

In the spring of the present year we referred briefly to the attempt being made by Dr. J. M. Hildebrandt, under the auspices of the Berlin Academy of Sciences, to ascend the snow-covered summit of Mount Kenia. The question as to the permanent snow covering of the two equatorial mountains, Kenia and Kilimandscharo, has been a subject of so much controversy among geographers, that the results of this expedition have been looked for with great interest. It is with regret that we learn from a communication of Dr. Hildebrandt's, dated Suez, November 2, that he has been compelled to return, leaving the summit of Kenia still untrodden by the foot of a European. He left Mombassa on January 10 with forty attendants, and after two months of exhaustive travel amidst hostile tribes, reached Kitui, in Ukamba. Here, in full sight of Kenia, he was compelled to pause and retrace his footsteps, his followers utterly refusing to venture among the marauding tribes intervening between him and his journey's goal, and he himself being only saved by the swift application of an antidote from death by poison given by the natives. On reaching Zanzibar the physicians declared his health impaired to such an extent that restoration could only be hoped for in a more temperate clime. Dr. Hildebrandt has suffered unusually from the two invariable concomitants of the African explorer—sickness and the hostility of the aborigines, his two expeditions from Zanzibar in the spring and autumn of 1875 being both shortened and hampered by these causes.

Herr Schutt, a civil engineer, has been despatched by the German African Society to St. Paul de Loanda to undertake an expedition through the region lately traversed so successfully by the hunter, Dr. Pogge.

One of the effects of the war in the east appears to be the discovery in out-of-the-way towns in Russia, of gems of unsurpassed size and beauty, which doubtless have been jealously hoarded by their possessors, and only brought to light in times, like the present, of national necessity. Some of these gems have naturally found their way to this country; perhaps the most remarkable are—an aquamarine, far superior to anything before seen in England, weighing over six ounces and a half, without the slightest blemish, and of a deep sea-green tint; also a topaz rivalling that purchased for the Grand Mogul at Goa for 11,260*l*. These two remarkable gems were received from Moscow by Mr. Bryce M. Wright, Mineralogist, of Great Russell Street, the possessor of the unique suite of diamonds called the "Bryce Wright Diamonds," valued at 21,000*l*.

We are requested to state that in the abstract of Mr. Perkin's paper read at the meeting of the Chemical Society on November 1 the word "cumenyl" was, by a slip, written "cinnenyl" throughout the report.

The additions to the Zoological Society's Gardens during the past week include a Common Squirrel (*Sciurus vulgaris*), European, presented by Mr. T. Massey, F.Z.S.; a Greater Sulphur-Crested Cockatoo (*Cacatua galerita*), from Australia, presented by Mr. F. Lablache; a Radiated Tortoise (*Testudo radiata*) from Madagascar, presented by Mr. H. Harrison; two Red-backed Squirrel Monkeys (*Saimaris œrstedi*), two Black-handed Spider Monkeys (*Ateles melanochir*), a Derbian Opossum (*Didelphys derbianus*) from Central America, a Bonnet Monkey (*Macacus radiatus*) from India, a Rufous-vented Guan (*Penelope cristata*) from Costa Rica, deposited; a Bay Antelope (*Cephalophus dorsalis*) from West Africa, received in exchange.

THE LIBERTY OF SCIENCE IN THE MODERN STATE[1]

When the honourable request was addressed to me by our committee to deliver a lecture to the meeting upon this occasion, I asked myself whether I should not treat of a special department of the latest development of science, in accordance with that point of view to which I drew attention originally, and of which you were reminded by Prof. Klebs only the other day. But I decided this time to give expression to a more general want, principally because it seems to me that the time has come when a certain explanation must take place between science as we represent it and work in it, and general life as a whole, and because in the special history of the continental nations of Europe the moment is rapidly approaching when the mental fate of nations by decisions in the highest quarters may be determined perhaps for a long time to come.

It is not for the first time, gentlemen, that upon the occasion of a meeting of this Association I have been able, as a warning, to point out almost dramatic events happening in our neighbouring state. On a former occasion I could draw attention to occurrences which had just taken place beyond the Rhine, and which, however far they may apparently be removed from our task, yet concern the same contested domain after all, that namely upon which a decision must be made with regard to determining what position modern science is to occupy in the modern state. Let us be sincere—here we may perhaps be doubly so,—it is the question of ultramontanism and of orthodoxy, which moves us continually. I may say that I look forward with real fear to the events which will happen among our neighbours in the course of the next years. We here, at this moment, may look round with a certain pride and we may observe the course of things with a certain calmness. But to-day, when we are celebrating the fiftieth anniversary of this Association, it is certainly becoming to remember how great a change has taken place in Germany, and specially at Munich, since the days when Oken assembled German naturalists and physicians for the first time.

I would only refer shortly to two facts; they are well-known enough, but then they are also important enough to be mentioned again. The one is that when, in the year 1822, the handful of men who constituted the first meeting of the German Association of Naturalists met at Leipzig they thought it still so dangerous to hold a meeting of that description that it was really held in perfect secrecy. The names of the Austrian members could indeed be published only thirty-nine years later, viz., in 1861. The second fact which strikes us when we remember Oken is, that he, the valued and renowned teacher, the ornament of the Munich high school, died in exile in the same canton of Switzerland in which Ulrich von Hutten ended his life full of troubles and contests. Gentlemen, the bitter exile which oppressed the last years of Oken's life, which caused his death far away from those scenes where he had sacrificed the best powers of his life, this exile will remain the signature of the time which we have gone through. And as long as there is a German Association of Naturalists, we shall thankfully remember that this man bore all the signs of a martyr until the time of his death, we shall point him out as one of those who with their blood conquered and obtained for us the liberty of science.

Nowadays, gentlemen, it is easy to speak of the liberty of science in Germany; now we are perfectly secure even here, where, only a few decades back, the fear was great that a new change of things might perhaps produce the extreme reverse, and we can in all calmness discuss the highest and most difficult problems of life and the hereafter. The addresses which were delivered at the first and second general meetings certainly prove sufficiently that Munich is now a place which can bear to hear the representatives of science in the most perfect liberty. I was not able to listen to all these addresses, but I have since read those of Professors Haeckel and Nägeli, and I must say we cannot ask more than to be allowed to continue to discuss with such liberty.

If it were only a question of rejoicing over this possession I should indeed not have claimed your attention for that object. But, gentlemen, we have arrived at a point when it becomes necessary to investigate whether we may hope to retain securely for the future the possession which we actually enjoy. The fact that we are enabled to discuss, as we do to-day, is not a sufficient security that it will always remain so for one who, like myself, has had many years' experience of public life. Therefore I think

---

[1] Address delivered at the Munich meeting of the German Association, by Prof. Rudolf Virchow, of Berlin.

for the moment, but [illegible] what we are to do to maintain the present state of things. I will tell you at once, gentlemen, what I would represent to you as the chief result of my observations, what I would like to prove here principally. I would like to show that for the present we have nothing more to ask, but that on the contrary we have arrived at the point when we must make it our special task to render it possible, *through our moderation, through a certain resignation with regard to personal opinions and predilections* that the favourable disposition of the nation towards us, which we now enjoy, does not change to the contrary!

In my opinion we are really in danger of doing harm to the future, by making use too amply of the liberty which the present state of things offers us, and I would warn you not to continue in the arbitrariness of personal speculation, which now claims prominence in many domains of natural science. The explanations which my predecessors have given you, those of Prof. Nageli in particular, will yield a series of the most important points of view, with regard to the course and limits of natural knowledge, to all who read them, and it cannot be my task to repeat them. But I must point out in reference to them, and I would like to adduce a few practical instances from the experience of natural science, how great a difference there is between what we give out as real science in the strictest sense of the word, and for which alone we may in my opinion claim the totality of all those liberties which we may designate as liberty of science, or, if we express ourselves still more exactly, as *liberty of scientific teaching*,—and that larger domain, which belongs more to speculative expansion, which sets problems, and finds the tasks to which modern investigation is to be applied, and which anticipatively formulates a series of doctrines, which are still to be proved, and the truth of which must yet be found, but which in the mean time may be taught with a certain amount of probability, in order to fill certain gaps in knowledge. We must not forget that there is a limit between the speculative domain of natural science and that which is actually proved and perfectly determined. The demand is addressed to us that this limit shall be not only occasionally pointed out, but fixed with the greatest exactness, so that each single worker shall at all times be perfectly conscious of where the limit is drawn, and how far he may be requested to admit that what is taught is actual truth. That, gentlemen, is the problem which we have to work out *in ourselves*.

The practical questions which are connected with this, lie very near. It is evident that for whatever we consider to be secured scientific truth, we must demand the complete admission, into the scientific treasure of the nation. *This the nation must admit as part of itself*—it must consume and digest it, and continue to work at it. Just in this lies the double promotion which natural science offers to the nation:—On the one hand the material progress, that enormous progress which has been made in modern times. Everything which the steam engine, telegraphy, photography, chemical discoveries, the research into colours, &c., have produced, all this is essentially based on this—that we, the men of science, complete the doctrines entirely, and when they are perfectly complete and secure, so that we know with certainty that they are natural scientific truths, that we then give them to the nation at large; then others can work with them as well, and can create new things, of which formerly nobody had any idea, of which nobody dreamt, which come into the world as perfect novelties, and which reform the condition of society and of states. This is the material significance of our labours. The mental importance, on the other hand, is similar. If I present the nation with a certain scientific truth which is completely proved, to which not the least doubt attaches, if I demand that everybody shall convince himself of the correctness of this truth, that he shall assimilate it, that it shall become part of his thought, then I suppose as a matter of course, that his conception of things generally must be affected by it. Each essentially new truth of this kind must necessarily influence the whole method of conception of man, the *method of thinking*.

If, for instance, to refer to a case in point which lies near, we consider the progress which has been made during recent years with regard to the knowledge of the human eye, beginning at the time when the single component parts of the eye were first anatomically separated, when these single and anatomically separated parts were first examined microscopically and their different arrangement shown, down to the time when we gradually learned to know the vital qualities and the physiological functions of the different parts, until at last, by the discovery of the retina-purple (*Sehpurpur*) and of its photographic properties, a progress was made of which but a year ago we hardly had an idea, then it is evident that with each progressive step of this kind a certain part of optics, particularly the doctrine of vision, is determined and changed. By this we learn in a perfectly certain manner how the action of light takes place in the interior of the human body itself, and that it is quite an outside organ of the human body, not the brain, but the eye which experiences this action. We learn by it that this photographic process is not indeed a mental operation, but a chemical phenomenon, which occurs by the help of certain vital processes, and that in reality we do not see the external things, but their images in our eye. We are thus enabled to gain a new analytical fact for the knowledge of our relations to the world outside of us, and to separate more distinctly the purely mental part of vision from the purely material part. Thus a certain part of optics, and through it one of psychology, is entirely reformed. Chemistry now steps in to investigate questions which up to the present were entirely out of its range, particularly the highly important questions, What is retina-purple? What substance is this? How is it formed, how decomposed, and how again formed? The solution of these questions will not fail to open an entirely new field for investigation; let us hope that also on the field of technical photography we shall soon make some progress, that we shall learn how to produce many-coloured photographs. Thus a mixture of steps of progress is formed, which belongs partly to the material and partly to the mental domain. And I therefore say, that with each true step of progress in natural knowledge a series of changes must necessarily take place in the internal relations of the human race as well as in the external ones, and nobody can prevent new knowledge from influencing him in a certain sense. Each new part of real knowledge works on in man, it produces new conceptions, new trains of thought, and nobody can avoid, after all, placing even the highest problems of the mind into a certain relation with natural phenomena.

But there is still another side of practical consideration which lies far nearer to us. Everywhere in the entire German Fatherland we are now occupied in remodelling educational affairs, in enlarging and developing them, and in determining their precise forms. The new Prussian educational law is on the threshhold of coming events. In all German states larger school-houses are being erected, new institutions are founded, the universities are enlarged, high schools and middle schools are established. At last the question arises, What is to be the principal tenor of what is taught? Where shall the school lead to? In what directions shall it work? If natural science demands, if we have been exerting ourselves for years to obtain an influence in our schools, if we demand that natural knowledge shall be admitted into education in a much larger measure, so that this fertile material be offered early to the youthful minds, in order to form the basis of a new conception, then we must indeed own that it is high time that we understood one another with regard to what we can and will demand. If Prof. Haeckel says that it is a question for pedagogues whether the theory of descent is now to form the basis of instruction, whether the plastidule soul is to be adopted as the basis of all considerations regarding mental phenomena, and whether the phylogeny of man is to be followed up into the lowest classes of the organic empire, and even beyond it up to spontaneous generation, then this is, in my opinion, a mere shifting of tasks. If the theory of descent is as certain as Prof. Haeckel thinks it is, then we must demand its admission into the school, and this demand is a necessary one. How could we imagine that a doctrine of such importance, which influences the conscience of everybody in so revolutionary a manner, which creates directly a sort of new religion, should not be entirely incorporated into the educational plan! How would it be possible to ignore such a revelation—as I may indeed call it—in our schools, and to kill it by silence as it were, or to leave the transmission of the greatest and most important steps of progress, which our conceptions have made in the whole century, to the option of the pedagogue? Indeed, gentlemen, that would be a resignation of the most severe kind, and in reality it would never be exercised. Every schoolmaster who might receive this doctrine in his mind would teach it as well, even unconsciously. How could he do otherwise? He would have to simulate altogether, he would have to rob himself at times of his own knowledge in the most artificial manner, in order not to show that he knew and recognised the theory of descent, and that he knew exactly how man has originated and whence he comes. If indeed he did not know where man goes to, yet he would at least believe that he knew for certain how in the course of æons the progressive series shaped itself. Therefore I say that if we really did not demand the admission of the theory of descent into the educational plan, this would *yet be accomplished of its own accord.*

We certainly should not forget, gentlemen, that what here we express, perhaps still with a certain timid reserve, is propagated by those outside with a confidence increased a thousand-fold. For instance, I have once pronounced the phrase—in opposition to the doctrine then reigning of the development of organic life from inorganic matter—that each cell had its origin in another cell, indeed at that time with special reference to pathology, and principally with regard to man himself. I may remark here that in both relations I still to-day consider this phrase a perfectly correct one. But when I had pronounced this doctrine and had formulated the origin of the cell from the cell, others were not wanting who extended this phrase not only in the organic world far beyond the limits for which I had intended it, but who put it down as generally valid even beyond the limits of organic life. I have received the most wonderful communications both from America and Europe, in which the whole of astronomy and geology were based upon the cellular theory, because it was thought impossible that something which was decisive for the life of organic nature upon this earth should not be equally applied to the heavenly bodies, which were said to be round bodies after all, and which had shaped themselves into globes and represented so many cells flying about in universal space and playing a part there similar to that of the cells in our body.

I cannot say that the authors of these communications were all decided fools and simpletons; on the contrary, from some of their explanations I gained the idea that many an otherwise educated man, who had studied much and finally attacked the problems of astronomy, could not understand that the utility of heavenly phenomena should be based upon something else than the utility of human organisation, so that he, in order to gain a monistic conception eventually arrived at the supposition that the heaven must also be an organism, that indeed the whole world must be an organism of useful arrangement, and that no other principle but that of the cells could apply to it. I cite this only in order to show what shape things take outside, how "theories" are enlarged, and how our own doctrines may return to us in a form fearful to ourselves. Now only imagine how the theory of descent may be shaped to-day in the head of a socialist!

Indeed, gentlemen, this may seem ridiculous to many, but it is very serious, and I only hope that the theory of descent may not bring all those horrors in our country which similar theories have actually brought to our neighbours. Anyhow this theory, if carried through to its consequences, has an extremely dangerous side and that the socialists have a certain notion of it already, you will doubtless have remarked. We must make this quite clear to ourselves.

Nevertheless the matter might be as dangerous as possible, the confederates might be as bad as they could be, and yet I say, from the moment when we are convinced that the theory of descent is a doctrine perfectly proved, so certain that we could swear by it, that we could say, thus it is,—from that moment we must not hesitate to introduce it into general life, transmit it not only to every educated person, but teach it to every child, make it the basis of our whole conception of the universe, of society, and of the state, and found our educational system upon it. This I consider a necessity.

In saying this I am not at all afraid of the reproach, which to my astonishment has made a great noise in my Prussian Fatherland, while I was absent in Russia, I mean the reproach of *half-knowledge*. Strange to say, it was one of our so-called liberal journals which asked the question whether the great faults of our time, and socialism in particular, were not based upon the diffusion of half-knowledge. With reference to this I would like to state here, in the midst of the Naturalists' meeting, that *all* human knowledge is only piece-work. All of us who call ourselves naturalists, only possess pieces of natural science; none of us is able to come here and represent each science with the same right, or participate in the discussions of any scientific section. On the contrary, it is just because they have developed themselves in a certain one-sided direction, that we esteem the special scientific men so highly. On the other fields we are all in half-knowl[illegible] as it were. Oh! that we could only succeed in diffusing this half-knowledge more and more, if we could succeed in causing at least the majority of educated persons to progress far enough to be able to survey the principal directions which the single departments of natural science are taking, and to follow their development without meeting difficulties too great to be overcome, so that they would at least be aware of the general progress of science, if, indeed, they were not acquainted, at every moment, *with the totality of all single and special proofs.* We do not get much further ourselves. I, for instance, have honestly tried during my time of life to obtain chemical knowledge; I have even worked in a laboratory, but I feel thoroughly incompetent to sit down at some chemical meeting without preparation, and to discuss modern chemistry in all directions. Nevertheless I am able to penetrate, after a time, so far into any chemical novelty that it does not strike me as incomprehensible. But I must always first acquire this understanding, I have not got it to start with; and when I want it again I must acquire it again. That which honours me is the *knowledge of my ignorance*. The most important part is that I know perfectly well what I do *not* know of chemistry. If I did not know that then of course I should always be wavering to and fro. But as I imagine that I am tolerably well aware what I do not know, I say to myself every time I am obliged to enter a domain which is still closed to me: "Now I must begin again to learn, now I must study afresh, now I must do as anybody does who enters the domain of science." The great error, which is equally shared by many educated people, consists in not remembering that with the enormous extent of natural science and with the inexhaustible quantity of detailed material, it is impossible for any single person alive to command the totality of all these details. That we get far enough to know the *foundations* of natural science and the gaps which exist in our own knowledge, so that every time we find a gap of this kind we say to ourselves,—"Now you enter a domain which is unknown to you,"—that is what we must arrive at. If everybody was only sufficiently aware of this, many a one would beat his breast and own that it is a dangerous thing to draw general conclusions with regard to the history of all things when one is not even entirely master of the material from which these conclusions are to be drawn.

(*To be continued.*)

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIDGE.—This term has witnessed the election of two new Natural Science fellows. Mr. A. M. Marshall, Senior in the Tripos of 1874, has been elected at his own College, St. John's. His able papers on Embryology have been an important addition to the researches which are making the British school again famous in this subject, and he is the first Doctor of Science in Comparative Anatomy in the University of London. Two of the newly-elected fellows of St. John's are taking to Medicine, viz., Dr. Marshall and Mr. McAlister, the last Senior Wrangler. At Trinity the open fellowship has been adjudged for the first time to a non-member of the College, Mr. J. N. Langley, B.A., of St. John's, whose services as Demonstrator of Physiology to Dr. Foster are most highly appreciated, while his originality and perseverance in research will, before long, be much more widely known than at present. I understand that the aid of Prof. Huxley was called in, giving the highest guarantee to the examination in Biology, and that several candidates showed themselves in every way worthy of a fellowship, especially in the original memoirs which were sent in before the examination.

The new buildings for anatomy and physiology are advancing to completion and are partially occupied, Mr. Balfour's two practical courses of Comparative Anatomy being accommodated in them. Dr. Foster will transfer much of his work here after Christmas. The new buildings will be almost too small as soon as completed, for Dr. Foster has fifty men and several ladies working in his elementary classes this term, a very large number when it is considered that this is voluntary and not prescribed work. It is but a just tribute to Dr. Foster's rare value as a teacher who makes his students think, who sacrifices his time most indefatigably for their interests, and who cultivates the powers of investigation developing in his pupils with all the care of a parent. Instead of engrossing authority to himself, he sets his senior pupils to lecture on the subjects they make a special study; thus during the present winter the advanced class will receive lectures from Dr. Gaskell, Mr. Langley, and Mr. Lea. Mr. Vines has returned from working in Germany with Sachs, and is lecturing to a large class on Vegetable Physiology. Next year he will start the first practical course of botany, and, being unable to induce his college to provide apparatus for a laboratory, intends to furnish it at his own expense. Among other lectures in natural science Prof. Dewar's on Physical Chemistry are taking high rank. It is to be noted that Mr. Apjohn, the late lamented Prælector of Chemistry at Caius College, was to have received a fellowship this term by special vote of the whole of the fellows. The prælectorship is to be continued mostly in its old form, but it is worthy of note that the prosecution of original research is put prominently among the duties of the office, as well as the instruction of students from the University generally. There are nearly a score of candidates, including such well-known names as Mr. W. Noel Hartley, Dr. J. T. Bottomley, and Dr. Dittmar.

Prof. Clerk Maxwell greatly interested the Philosophical Society at its last meeting by an account of Henry Cavendish's unpublished writings and experiments on electricity. He was not generally known to have done much electrical work, and his papers were long in the hands of Sir W. Snow Harris, who is declared by Prof. Maxwell, after careful examination, to have made no use of Cavendish's work without full and adequate acknowledgment. These writings are left in a form quite fitted for publication, and will greatly advance the reputation of the great philosopher. His exactness, his candour, his grasp of the subject, his notable achievements with the small variety of instruments available in his time, were fully shown by the examples cited to the Society. Yet these were less than his remarkable insight into electrical laws, his correct conception of potential, his ideas of investigating the total charges of bodies, and the resistance of electrolytes. Prof. Maxwell thought that nobody had ever possessed so large and various a collection of condensers of known capacity as Cavendish, but his family taciturnity prevented his merits from being fully known. He trained himself to be his own galvanometer, and the general value of his results is remarkable when compared with those obtained by modern instruments.

In regard to university reform, it appears that in some colleges at least there is a danger of the non-resident fellows, who form the largest proportion of the governing body under the act, endeavouring to maintain at a very high number the fellowships to which no duties are attached; of course every such fellowship diminishes the funds available for definite association with the progress of research and education. Some men hold very strongly to the "start in life" theory of fellowships; viz., that they ought to receive three hundred a year for a number of years in order that they may gain three thousand a year in a profession the more speedily.

GLASGOW.—Mr. Gladstone has been elected Lord Rector of Glasgow University in succession to the Earl of Beaconsfield.

BERLIN.—The well-known botanist, Prof. Sachs, of Würzburg, has received a very flattering call to Berlin. Neither pains nor money seem to be spared by the Prussian Government in attracting to the capital the foremost talent of Germany; and certainly in this choice of a successor to Alexander Braun no change of policy is shown.

GOTTINGEN.—The sum of 50,000 marks has recently been appropriated for the erection of a phyto-physiological institute in the Botanical Gardens.

GIESSEN.—In consequence of the late discussions excited by Prof. Mommsen's articles on the Ph.D. examinations in Germany, the University of Giessen has issued an announcement stating that for the future no faculty can bestow the title of Doctor, except on the basis of a thesis and oral examination.

DORPAT.—The winter attendance at the university is 853, of whom but seven are non-Russian.

BRUNSWICK.—On October 16 interesting ceremonies took place at the opening of the magnificent new buildings of the Carolo-Wilhelminum Polytechnic, in which representatives of the Government, and delegates from all the great German polytechnics, took part. The new edifices are of great extent, and richly equipped with all possible adjuncts for modern technical education, so that this well-known institution will be able to maintain its well-earned reputation. The Carolo-Wilhelminum is the oldest polytechnic in Germany, having been founded in 1745, and the list of its students embraces many distinguished names, such as Gauss, the mathematician, Christopher Codrington, the English commander at the naval victory of Navarino, &c.

SOCIETIES AND ACADEMIES

LONDON

Chemical Society, November 15.—Dr. Gladstone in the chair.—The following communications were made:—First report to the Chemical Society on some points in chemical dynamics, by Dr. Wright and Mr. Luff. An elaborate series of experiments was made to find out the temperatures at which the actions of carbonic oxide, hydrogen, and free amorphous carbon on oxide of iron or oxide of copper are first perceptible. The authors find that this temperature varies with the physical condition of the oxide used, that hydrogen acts, on a given oxide, at a lower temperature than carbon and carbonic oxide, at a lower temperature than hydrogen, and that a given reducing agent begins to act on copper oxide at a lower temperature than on iron oxide.—On the chemistry of cocoa butter, Part I.; two new fatty acids, by C. T. Kingzett. The first acid is a low acid of the series, $C_nH_{2n}O_2$, having the formula $C_{12}H_{24}O_2$, *i.e.*, lauric acid, but it melts at 57°·5. The second acid is a high acid having the formula $C_{64}H_{128}O_2$, crystallising in microscopic needles or granules, melts at 72°·2, and at a high temperature distils apparently unchanged. The author proposes for it the name of theobromic acid. It is pointed out that the usual statement in books, "that cocoa butter yields almost exclusively stearic acid" is entirely incorrect.—The third paper was on the influence exerted by time and mass on certain reactions in which insoluble salts are produced, by Mr. M. P. Muir. The author has taken solutions containing known quantities of calcium chloride and potassium or sodium carbonate mixed, allowed to stand for a certain number of minutes, and then estimated the quantity of calcium carbonate formed. He has arrived at the following conclusions:—That the greater portion of the chemical change takes place during the first five minutes; the reaction then decreases in rapidity. The relative masses of the salts exert an important influence. Thus if the mass of alkaline carbonate be four times that required, the action is completed in five minutes, but if an equivalent quantity only be present the action is not finished in forty-six hours. Potassium carbonate yields more calcium carbonate in a given time than sodium carbonate. An increase of temperature increases, whilst dilution, especially with solutions of potassium or sodium chloride, diminishes the rapidity of the action. Some experiments are given on the action of solutions of calcium sulphate and sodium chloride.

Entomological Society, November 7.—Prof. Westwood, president, in the chair.—Mr. McLachlan exhibited ten of the thirteen species of Lepidoptera collected by Capt. Feilden and Mr. Hart in Grinnell Land, between 78° and 83° N. lat, during the recent Arctic Expedition, and made some remarks upon the general insects of the Arctic Regions.—The Rev. A. Eaton also made some observations upon the same subject.—Mr. Meldola exhibited a five-winged specimen of *Gonepteryx rhamni*, taken in Norfolk by Mr. John Woodgate; likewise a gynandromorphic specimen of *Pieris brassicæ*, caught in Oxfordshire by Mr. J. B. Watson. The right half of the latter insect was female and the left half male.—Mr. H. Goss exhibited a gynandromorphic specimen of *G. rhamni*, captured in Sussex; in this insect also the right side was female and the left side male.—Mr. J. W. Douglas exhibited a specimen of *Polyphylla fullo*, Linn., which had flown on to a steamer at Antwerp, and been thus brought to this country. Mr. Douglas also exhibited a specimen of the rare *Tettigometra impressopunctata* and one of *Typhlocyba debilis*, both taken on Sanderstead Downs; and likewise, for comparison, an example of *T. tenerrima*.—Mr W. C. Boyd exhibited a larva of *Pieris rapæ* attacked by *Microgaster*.—The president read notes on exotic Coleoptera, and exhibited specimens of *Calometopus Nyassæ*, *Amblyodus Nicaraguæ* and drawings of other species.—Prof. Westwood also remarked upon an Indian *Mantis* (*Gongylus gongylodes*) which had been recently described by Dr. Anderson in the *Proceedings* of the Asiatic Society of Bengal for August, 1877, as being a simulator of a flower to a remarkable degree of perfection.—Mr. Wood-Mason also made remarks upon the same subject and upon stridulating organs in crustaceans with reference to a letter on this subject by Mr. Saville Kent in this journal (vol. xvii. p. 11). Mr. Wood-Mason likewise announced the discovery of a stridulating apparatus in a *Phasma*.—Sir Sydney Saunders read a note on the specific identity of the Hampstead *Atypus*. Mr. F. Enoch exhibited and made remarks upon a male and female of this spider.—The following papers were read:—Descriptions of new species of the coleopterous genus, *Callirhipis* (*Rhipidocerida*), in the British Museum, by C. O. Waterhouse.—Descriptions of a new genus and two new species of *Sphingidæ*, with remarks on the family generally, by A. G. Butler.—Descriptions of *Halticinæ*, by J. S. Baly.—Descriptions of new species of *Cleridæ*, with notes on the genera and corrections of synonymy, by the Rev. H. S. Gorham.

Royal Astronomical Society, November 9.—Dr. Huggins, F.R.S., in the chair.—A very large number of papers were presented.—Lord Lindsay was called upon to read Mr. Gill's report upon the expedition to Ascension to obtain the parallax of Mars, from which it appeared that in spite of meteorological difficulties and many causes of anxiety most satisfactory results had been obtained, and Mr. Gill had gone up a mountain to recruit his health.—Several important mathematical papers were then read; one by the Astronomer-Royal on the solar parallax, as deduced from telescopic observations of the transit of Venus, 1874.—Next a paper by Prof. Adams on the motion of the moon's node, and a paper by Mr. Neison on three small inequalities in the mean motion of the earth, and a small inequality in the mean motion of Mars. These were followed by three observational papers on the recent opposition of Mars; one by the Astronomer-Royal, read by Mr. Christie, giving the summary of what was seen at Greenwich both with the telescope and spectroscope; the next by Mr. N. E. Green, giving an account of his expedition to Madeira and what he saw of Mars with a fine 13 inch reflector. This paper was accompanied by a series of beautiful drawings of the planet by the author. The third paper, on Mars, was by Mr. John Brett, being a discussion of a series of telescopic observations made in Cornwall, the purport of which was to show that the generally received hypothesis of the physical condition of Mars was altogether fallacious, neither the snows nor the seas having any foundation in fact. This paper was also illustrated by a series of drawings.—Then followed a paper by Lord Lindsay, on a new form of spectroscope, and the meeting adjourned.

Anthropological Institute, November 13.—Dr. John Evans, F.R.S., president, in the chair.—The Rev. T. A. Bennett and F. V. Dickins were elected members.—An interesting series of casts of skulls made of papier-maché were exhibited, and a special vote of thanks was ordered to be sent to Prof. Bogdanow, of Moscow, by whom they were presented to the Institute.—Major-Gen. A. Lane Fox, F.R.S., exhibited some flint flakes from Egypt, and a note from Capt. R. F. Burton was read on the same.—The director then read a paper by Mr. H. H. Howorth, F.S.A., on the spread of the Slaves: Part I., the Croats.—This was followed by a paper on the Castilieri d'Istria, by Capt. R. F. Burton, H.M.'s Consul at Trieste.—Mr. Hyde Clarke, the President, Major-Gen. A. Lane Fox, and Mr. Moggridge took part in the discussions.

Institution of Civil Engineers, November 13.—Mr. George Robert Stephenson, president, in the chair.—The paper read was a review of the progress of steam shipping during the last quarter of a century, by Mr. Alfred Holt, M. Inst. C.E., of Liverpool.

Paris

Academy of Sciences, November 12.—M. Peligot in the chair.—M. Faye presented the volume of the *Connaissance des Temps* for 1879.—On some applications of elliptic functions (continued), by M. Hermite.—*Résumé* of a history of matter (fourth article) by M. Chevreul. This relates to the views of Lavoisier, Stahl, Scheele, Cavendish, and Priestley.—Observations on the principle of maximum work and on the spontaneous decomposition of hydrated bioxide of barium, by M. Berthelot.—On the limits of etherification, by M. Berthelot. In experimenting on etherification sixteen years ago he put aside a number of mixtures to be kept a considerable time, in order to ascertain the limit of the reactions produced at ordinary temperatures. The mixtures consisted of acetic acid and alcohol (equal equivalents), acetic acid and glycerine, tartaric acid and alcohol, valeric acid and alcohol. He has now examined these. The general laws of etherification are confirmed, and especially the identity of the limits of combinations between acids and alcohols, from ordinary temperatures up to 260°.—On the order of appearance of the first vessels in the shoots of some Leguminosæ (second part), by M. Trécul.—The Academy elected a commission to present a list of candidates for the vacancy among the Foreign Associates, caused by the death of M. von Baer.—On the numeration of globules of milk for the analysis of woman's milk, by M. Bouchut. A drop of milk is mixed with 100 drops of slightly saline water (distilled). A drop of the mixture is placed under the microscope, whose eye-piece is divided into squares; the number of globules in each square is counted, and the average taken; from this may be deduced the number in one cubic millimetre. The globules were thus counted in milk of 158 nurses, before, during, and after suckling. The average of globules is about 1,026,000 per cubic millimetre of milk, or a hundred and two milliards six hundred millions per litre; but between 800,000 and one million per cubic millimetre, the milk is considered of good quality. In one table are given the density and the quantity of butter corresponding to given numbers of globules of cow's milk.—New formulæ for the study of the motion of a plane figure, by M. Haton de la Goupillière.—On the migration of the puceron of the cornel tree and its reproduction, by M. Lichtenstein. This puceron comes from the roots of gramineæ, and returns to them. Its mode of reproduction is that termed by the author *anthogenesis*.—Observations on the subject of a recent communication from M. Fabre, by M. Millardet. The secretary announced a new biennial prize, founded by M. Maujean.—Discovery of a small planet at the Observatory of Paris, by M. Paul Henry.—Discovery of a small planet at the Observatory of Pola, by M. Palisa.—Observations of planets 125 and 176 made at the Paris Observatory (equatorial of the garden), by MM. Paul and Prosper Henry.—New stellar systems, by M. Flammarion.—On the equation with partial derivatives of the third order expressing that the problem of geodesic lines, considered as a problem of mechanics, supposes an algebraic integral of the third degree, by M. Lévy.—On the evolution of red corpuscles in the blood of oviparous vertebrates, by M. Hayem. The red corpuscles proceed from a peculiar colourless element, which from the first phases of development is distinct from the white corpuscles; the name of *hematoblast* is given it. The white corpuscles are foreign to the formation of the red, both in oviparous vertebrates and in the higher animals; but whereas in the latter the red corpuscles of new formation are coloured, whatever their minuteness, in the oviparous, the embryonic corpuscles are at first quite without hæmoglobin.—On the spots and crevices of pears, by M. Prillieux. These are due to the growth of a small parasitic champignon.—On the semi-diurnal variations of the barometer, by M. De Parville. He thinks it improbable that aqueous vapour has a preponderating influence in these variations.—On the quantities of heat liberated in mixtures of sulphuric acid and water, by M. Maumené. Sulphuric acid recently heated does not liberate, with water, the same quantity of heat as the same acid kept several months. This phenomenon, denoted as a tempering of liquids, seems to him a source of error in researches on thermo-chemistry not hitherto considered.

FLORA OF MAURITIUS AND SEYCHELLES

Flora of Mauritius and the Seychelles: a Description of the Flowering Plants and Ferns of those Islands. By J. G. Baker, F.L.S. (London: L. Reeve and Co., 1877.)

THIS compact volume of nearly 600 pages, adds another to the already long list of colonial floras prepared at Kew and issued under the authority and at the expense of the Colonial Government. It is arranged on the same plan as the other floras, many of them so well known, giving first, some general remarks on the physical geography and botany of the islands, and then that admirable outline of elementary botany prepared by Mr. Bentham, and which contains every definition necessary in descriptive botany, thus enabling the student to follow the technical descriptions given in the "Flora" itself. The work is almost entirely from the pen of Mr. J. G. Baker (the Orchids being by Mr. Le Marchant Moore, and the Palms and Pandani by Dr. I. B. Balfour), and is only another example of the indomitable industry so characteristic of Mr. Baker. The materials at the disposal of the author have been ample, and probably there is but little left to discover in Mauritius, the Seychelles, and Rodriguez, although many forms have not as yet been fully determined owing to the want of perfect specimens. Hence it is desirable that naturalists visiting the islands should endeavour to complete our knowledge of these imperfectly known plants. The smaller dependencies of Mauritius have not been explored botanically, hence there is probably a rich field for the investigator of these numerous islands. It is, moreover, all the more desirable to have these islands explored as the native flora of the islands already known has been completely altered by the introduction of cultivated plants and weeds as well as by the destruction of the native forests. Thus it is probable that in some of the undisturbed islands a rich native flora may be met with, or that some of the forms either rare or extinct on other islands, may yet be comparatively abundant.

Mauritius is about 39 miles by 35, and has an area of 700 square miles, or a little smaller than the County of Surrey. It is situated at a distance of about 500 miles from Madagascar and 100 miles from Bourbon, and is just within the Tropic of Capricorn. The northern part of the island is a low plain covered with sugar plantations. In the centre is an elevated plateau rising to about 1,500 feet above the sea-level, the great mass of the rocks being entirely volcanic. Outside the central plateau, and within a short distance of the sea, rise the three principal mountain ranges, the highest portions being from 1,900 to 2,900 feet in height. There are two small lakes in the central plateau, the Grand Bassin and the Mare aux Vacoas. There are six rivers, about ten to twelve miles in length, and numerous small rivulets. The climate is warm, and at Port Louis the mean annual temperature is 78° F. As a result, the vegetation has a decidedly tropical character. There are however, a few south temperate plants present, and also a number of the widely-spread temperate forms, as *Nephrodium filix-mas*, *Cardamine hirsuta*, *Juncus effusus*, *Convolvulus arvensis*, *Plantago major*, and *P. lanceolata*. Sugar is extensively cultivated in Mauritius. The increase in the cultivation of sugar has led to the destruction of the forests, which at one time covered the island to the water's edge. As a result of the destruction of the forests, the indigenous flora has almost become destroyed. The orchids, ferns, pandani, and the shade-loving plants, and the curious endemic trees and shrubs have, within 100 years, been either entirely exterminated, or else have become exceedingly rare and local. The native vegetation thus partly exterminated has been replaced by a number of introduced trees, shrubs, and weeds, to an extent only exceeded by the destruction of the indigenous flora of St. Helena. There seem to be about 269 introduced plants in Mauritius, and 869 undoubted native species, making a total flora of about 1,138.

The Seychelles are situated 900 miles north-east of Mauritius, in 3°-6° south latitude, and consist of a group of about thirty islands, most of them of very small size. The islands are entirely granitic. The largest of the group, Mahé, has an area of 30,000 acres; the best cultivated and most populous is La Digue, with an area of 2,000 acres. The mountains range from about 1,500 to 3,000 feet in height. The seasons are similar to those of Mauritius. Cotton was at one time extensively cultivated, and the aboriginal forests were destroyed to make room for cotton plantations. Now cotton is hardly cultivated, the chief exports from the island being cocoa-nut oil and fibre. The vegetation is wholly tropical; the few temperate species found in Mauritius being absent from the Seychelles. The number of flowering plants and ferns from these islands is 338. Five genera of palms and one genus of Ternstroemiaceæ are endemic. The endemic palms are mostly well known, and belong to the genera Deckenia, Nephrosperma, Roscheria, Verschaffeltia, Lodoicea, and Stevensonia. The total number of endemic species is sixty. The rest of the flora consists chiefly (250) of widely distributed tropical plants, and between twenty and thirty are of characteristic Mascarene types. The flora was expected to have been much richer in endemic forms from the isolated position and peculiar geological construction of the islands than it has proved to be after the most careful examination.

Rodriguez is situated 300 miles to the north and east of Mauritius, and is an island about eleven miles by five, with the hills in the interior reaching an elevation of little over 1,000 feet. The rock is entirely volcanic, and the climate similar to that of Mauritius. The flora must have undergone great changes, as the earliest records of the island state that it was entirely wooded. The plants of the island number about 202 wild flowering plants and ferns, nearly all collected by that rising young botanist, Dr. I. B. Balfour, one of the staff of the Transit of Venus Expedition to Rodriguez. Of the 202 wild species, thirty-six are peculiar to the island; and there are three endemic monotypic genera, one Mathurina having been discovered and described by Dr. I. B. Balfour.

The total number of species as given by Baker may be thus summarised:—There are 1,058 native species in the "Flora," 869 natives of Mauritius, 338 natives of Seychelles, and 202 native in Rodriguez; 269 are naturalised in these islands, thus giving a total number of 1,327 species included in the "Flora of Mauritius and the Seychelles." The distribution of the species in the flora is also interesting. Thus there are 304 endemic species, 232 Mascarene species, *i.e.*, plants confined to Bourbon, Mauritius, Madagascar, and the Comoros; 66 African but not Asian, 86 Asian but not African; 145 common to Asia and Africa; and 225 common to the Old and New World. If we take the percentages we have the following results:—29 per cent. endemic, 22 per cent. Mascarene, 21 per cent. common to the Old and New World, 14 per cent. common to Asia and Africa, 8 per cent. Asian but not African, and 6 per cent. African but not Asian. From this it is evident that one-half of the wild plants of the flora are restricted to the Mascarene Archipelago.

The orders containing the greatest number of species are the following:—Orchidaceæ, 79; Gramineæ, 69; Cyperaceæ, 62; Rubiaceæ, 57; Euphorbiaceæ, 45; Compositæ, 43; Leguminosæ, 41; Myrtaceæ, 20. There also 168 species of Filices, but it is rather unfair to consider the Filices as an order equivalent say to the Euphorbiaceæ or Myrtaceæ in the above enumeration.

The descriptive part of the flora is elaborated in the same manner as the colonial floras already published, and is, as already mentioned, almost entirely the work of Mr. Baker, with the exception of the Orchids, Palms, and Pandani. Any one acquainted with Mr. Baker's work will know that any detailed notice of the descriptive part of the present volume is superfluous.

W. R. McNab

OUR BOOK SHELF

Die Geologie. Franz Ritter von Hauer. (Vienna: A Holder, 1877.)

It is a good sign both of the progress of geological study in Austria and of the value of this manual by the director of the Austrian Geological Survey, that a second edition of the work has been called for within three years of the date of its publication. A sample of the revised issue which has been sent to us fully bears out the description on its title-page that it is enlarged and improved. The original work, besides its clearly-expressed introductory chapters on general dynamical and mineralogical geology, is especially a valuable repertory of information regarding the structure and palæontology of the Austro-Hungarian monarchy. In the new edition, Ritter von Hauer is evidently doing his best to keep his manual abreast of the time. The book is well-printed, but the author is still in the hands of a very poor wood-engraver. The new cuts are as rude and feeble as ever.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.]

Fritz Müller on Flowers and Insects

The enclosed letter from that excellent observer, Fritz Muller, contains some miscellaneous observations on certain plants and insects of South Brazil, which are so new and curious that they will probably interest your naturalist readers. With respect to his case of bees getting their abdomens dusted with pollen while gnawing the glands on the calyx of one of the Malpighiaceæ, and thus effecting the cross-fertilisation of the flowers, I will remark that this case is closely analogous to that of Coronilla recorded by Mr. Farrer in your journal some years ago, in which parts of the flowers have been greatly modified, so that bees may act as fertilisers while sucking the secretion on the outside of the calyx. The case is interesting in another way. My son Francis has shown that the food-bodies of the Bull's-horn Acacia, which are consumed by the ants that protect the tree from its enemies (as described by Mr. Belt), consist of modified glands; and he suggests that aboriginally the ants licked a secretion from the glands, but that at a subsequent period the glands were rendered more nutritious and attractive by the retention of the secretion and other changes, and that they were then devoured by the ants. But my son could advance no case of glands being thus gnawed or devoured by insects, and here we have an example.

With respect to *Solanum palinacanthum*, which bears two kinds of flowers on the same plant, one with a long style and large stigma, the other with a short style and small stigma, I think more evidence is requisite before this species can be considered as truly heterostyled, for I find that the pollen-grains from the two forms do not differ in diameter. Theoretically it would be a great anomaly if flowers on the same plant were functionally heterostyled, for this structure is evidently adapted to insure the cross-fertilisation of distinct plants. Is it not more probable that the case is merely one of the same plant bearing male flowers through partial abortion, together with the original hermaphrodite flowers? Fritz Müller justly expresses surprise at Mr. Leggett's suspicion that the difference in length of the pistil in the flowers of *Pontederia cordata* of the United States is due to difference of age; but since the publication of my book Mr. Leggett has fully admitted, in the *Bulletin* of the Torrey Botanical Club, that this species is truly heterostyled and trimorphic. The last point on which I wish to remark is the difference between the males and females of certain butterflies in the neuration of the wings, and in the presence of tufts of peculiarly-formed scales. An American naturalist has recently advanced this case as one that cannot possibly be accounted for by sexual selection. Consequently, Fritz Müller's observations which have been published in full in a recent number of *Kosm* are to me highly interesting, and in themselves highly remarkable.

Charles Darwin

Down, Beckenham, Kent, November 21

You mention ("Different Forms of Flowers," page 331), the deficiency of glands on the calyx of the cleistogamic flowers of several Malpighiaceæ, suggesting, in accordance with Kerner's views, that this deficiency may be accounted for by the cleistogamic flowers not requiring any protection from crawling insects. Now I have some doubt whether the glands of the calyx of the Malpighiaceæ serve at all as a protection. At least, in the one species, the fertilisation of which I have very often witnessed, they do not. This species, *Bunchosia gaudichaudiana*, is regularly visited by several bees belonging to the genera Tetrapedia and Epicharis. These bees sit down on the flowers gnawing the glands on the outside of the calyx, and in doing so the under side of their body is dusted with pollen, by which, afterwards, other flowers are fertilised.

There are here some species of Solanum (for instance *S. palinacanthum*) bearing on the same plant long-styled and short-styled flowers. The short-styled have papillæ on the stigma and apparently normal ovules in the ovary, but notwithstanding they are male in function, for they are exclusively visited by pollen-gathering bees (Melipona, Euglossa, Augochlora, Megacilissa, Eophila, n. g., and others), and these would probably never insert their proboscis between the stamens.

In a few months I hope to be able to send you seeds of our white-flowered violet with subterranean cleistogamic flowers.

was surprised at finding that on the Serra (about 1,100 metres above the sea) this violet produced abundant normal fruits as well as subterranean ones, while at the foot of the Sèrra, though it had flowered profusely, I could not find a single normal fruit, and subterranean ones were extremely scarce.

Acccording to Delpino the changing colours of certain flowers would serve to show to the visiting insects the proper moment for effecting the fertilisation of these flowers. We have here a Lantana the flowers of which last three days, being yellow on the first, orange on the second, purple on the third day. This plant is visited by various butterflies. As far as I have seen the purple flowers are never touched. Some species inserted their proboscis both into yellow and into orange flowers (*Danais erippus, Pieris aripa*), others, as far as I have hitherto observed, exclusively into the yellow flowers of the first day (*Heliconius apseudes, Colænis julia, Eurema leuce.* This is, I think, a rather interesting case. If the flowers fell off at the end of the first day the inflorescence would be much less conspicuous; if they did not change their colour much time would be lost by the butterflies inserting their proboscis in already fertilised flowers.

In another Lantana the flowers have the colour of lilac, the entrance of the tube is yellow surrounded by a white circle; these yellow and white markings disappear on the second day.

Mr. Leggett's statements about *Pontederia cordata* appear to me rather strange, and I fear that there is some mistake. In all the five species of the family which I know the flowers are so short-lived, lasting only one day, that a change in the length of the style is not very probable. In the long-styled form of our high-and Pontederia the style has its full length long before the flowers open. In my garden this Pontedaria is visited by some species of Augochlora collecting the pollen of the longest and mid-length stamens; they are too large to enter the tube of the corolla, and have too short a proboscis to reach the honey; they can only fertilise the long-styled and mid-styled forms, but not the short-styled.

Among the secondary sexual characters of insects the meaning of which is not understood, you mention ("Descent of Man," vol. i., p. 345) the different neuration in the wings of the two sexes of some butterflies. In all the cases which I know this difference in neuration is connected with, and probably caused by, the development in the males of spots of peculiarly-formed scales, pencils, or other contrivances which exhale odours, agreeable no doubt to their females. This is the case in the genera Mechanitis, Dircenna, in some species of Thecla, &c.

FRITZ MULLER

Blumenau, St. Catharina, Brazil, October 1

The Radiometer and its Lessons

PROF. OSBORNE REYNOLDS'S letter in NATURE (vol. xvii. p. 26) has directed attention prominently to the circumstance that two hypotheses have been submitted to the scientific world as explanations of the force and motions which Mr. Crookes had shown to exist—one by Prof. Osborne Reynolds, the other by myself.

Prof. Osborne Reynolds's explanation is based on the fact that when a disc with vertical sides is heated on one side and exposed to a gas, a convection current sets in, which draws a continuous supply of cold gas into contact with the hot surface of the disc. As this cold gas reaches the disc it is expanded, and thus its centre of gravity is thrown further from the disc. Accordingly, the disc, if freely suspended, will move in the opposite direction so as to keep the centre of gravity of the gas and disc in the same vertical line as before, and, if not freely suspended, will suffer a pressure tending to make it move in that direction. If I have understood Prof Reynolds aright, this is both a correct and full description of his explanation as last presented.

My explanation, on the other hand, is based on *molecular* motions which go on in the gas without causing any molar motion, and is independent of convection currents. Prof. Reynolds is therefore, I conceive, fully justified in denying that my theory has supplied any deficiency in his explanation. As he points out, the two explanations are incompatible; if either is correct, the other is wholly wrong.

It is easy to apply comparative tests to the rival hypotheses by making a selection from Mr. Crookes's incomparable experiments, from the experiments by Mr. Moss and myself, and from instances of compressed Crookes's layers in the open atmosphere; but it is not easy to make the choice so as to bring the abundant evidence within the compass of a letter.

These tests might take various forms, of which perhaps the most direct is to ascertain whether the force is affected by variations in the convection current, as required by Prof. Reynolds's hypothesis, or is independent of convection, but increased when the heater and cooler are brought nearer together, as required by mine.

To test this Mr. Crookes mounted a radiometer in a receiver consisting of two unequal bulbs connected by a large tube. The movable portion could be transferred from one bulb to the other through the tube. In the small bulb the convection current is most impeded, and at the same time the heater and cooler are closest together. Mr. Crookes found that the motion of the radiometer was more rapid in the small bulb than in the large one, in conformity with my theory, and in opposition to Prof. Reynolds's. The same is the uniform drift of a vast number of other experiments by Mr. Crookes, and of those by Mr. Moss and myself, from which it appears that whenever the heater and cooler are made to approach there is an increase in the force, and that the force is not appreciably affected by variations of the convection current, or by its suppression.

This may also be proved, and quite conclusively, by observations not requiring apparatus. Drops in the spheroidal state and the drops which are often seen floating on the surface of volatile liquids, as, for example, the drops which run about on the surface of the sea in certain states of the weather when water drips from an oar, are supported by Crookes's layers of air intervening between them and the liquid beneath. Similarly a red-hot copper plate will float on water, supported on a Crookes's layer, and many other instances of a like kind might be adduced. In such cases, where the film of air is thin and for the most part horizontal, it is manifest that there is no opportunity for those convection currents to arise which are required by Prof. Reynolds's hypothesis, while in all of them there are the peculiar molecular motions of my theory.

The absence of convection currents which could produce an appreciable effect may also be proved in those radiometers of which the arms whisk round at a very rapid speed, and in many other cases that would take too much space to describe here.

Again, a tangential force which may be rendered considerable is an immediate consequence of my theory, but has no place as a consequence of Prof. Reynolds's. Now its presence has been verified by Mr. Moss and myself, and by Mr. Crookes in an exquisitely beautiful apparatus suggested for this purpose by Prof. Stokes, as well as, in a less degree, in all Mr. Crookes's apparatus with curved or crumpled discs.

Hence Prof. Osborne Reynolds's hypothesis is not the explanation of Crookes's stress. It alleges a cause which is in certain cases a *vera causa*, but not *the* cause of what is to be explained. So far as I can form a judgment, its merit was collateral, and not intrinsic. It was the first attempt at a reduction of the observed phenomena to known physical laws. Though not accounting for them, it was sufficiently plausible to attract the attention of Prof. Reynolds and other physicists. It thereby had the important effect of suggesting Dr. Schuster's most valuable experiment, which was the first that established the cardinal fact that the forces within a radiometer case are balanced.

The conclusion to which we are thus led by a purely *experimental* inquiry is supported by an examination of the chief *theoretic* assertions of Prof. Osborne Reynolds's letter, viz. 1. That an essential part of my explanation "is contrary to the law of the diffusion of heat in gases;' and 2. "That the force arising from the communication of heat from a surface to adjacent gas of any particular kind depends only on one thing, the rate at which heat is communicated, and to this it is proportional."

Both of these statements have been set down by Prof. Osborne Reynolds in error; the first from not observing that the ordinary laws for the propagation of heat through a gas do not apply to compressed Crookes's layers; and the second from a misapprehension of the actual agency at work in radiometers and other similar apparatus. I will proceed to establish positions.

1. So long as a gas is in its ordinary state the distribution of the velocities of the molecules is the same in all directions, and when heat is imparted to the gas it does not disturb this uniformity of structure. The heat simply increases the mean velocity, and the actual velocities continue to be distributed about

their mean value according to the well-known exponential law, and are alike in all directions. But the gas of a compressed Crookes's layer is not in the ordinary state; it is under constraint, as I have elsewhere shown, owing to the proximity of the heater and cooler between which it is confined. In consequence of this constraint there are what I have described as processions going on in the layer of gas: in other words, *the velocities of the molecules at any situation within the layer are not alike in all directions, but are greatest in the direction of the cooler, least in the direction of the heater, and of intermediate values in lateral directions.* The heat in crossing the layer from the heater to the cooler maintains this polarised molecular structure, and if the flow of heat is increased it does not simply increase the mean velocity of the molecules, but also augments the disparity of the velocities in different directions.

Now the ordinary laws of the communication of heat to and through gas are based on the opposite supposition that when heat reaches any portion of the gas all the molecules of that portion are equally affected, that though their mean velocity is increased the laws of the distribution of the velocities about that mean, and in different directions, are not changed. Hence Prof. Osborne Reynolds has fallen into an error in applying the ordinary "law of the diffusion of heat in gases" to the case of compressed Crookes's layers. The law employed by Prof. Reynolds does not prevail unless there is sufficient room in front of the heater for the development of a complete *unrestricted* Crookes's layer; Crookes's force only presents itself when the thickness of that layer is restricted by a cooler.

The transmission of heat across Crookes's layers is made the subject of investigation in a memoir which I laid before the Royal Dublin Society last May, which has recently been printed in the *Transactions* of that body, and of which a copy will shortly appear in the *Philosophical Magazine.* The law proves to be entirely different from any of the laws for the propagation of heat hitherto known, and I have therefore called this mode of transferring heat by a new name—*the penetration of heat.* Moreover, the results of theory had been verified by anticipation more than thirty years before by MM. De la Provostaye and Desains, in two elaborate experimental investigations into what we now know to have been the penetration of heat; so that our knowledge of its laws, which are entirely different from the laws of the diffusion of heat, quoted by Prof. Reynolds, already stands on both a deductive and experimental basis.

2. Prof. Osborne Reynolds further states that with each gas the force depends only on one variable, viz., the rate at which heat is communicated by the heater to the adjacent gas, and that it is proportional to this rate. Probably owing to a mere slip on Prof. Reynolds's part, he has here omitted a second variable, viz., the temperature of the gas, which is implicitly contained in the equation of his first paper to which he refers. With this, however, I have no concern; what I have to point out is that in making the statement, whether in an amended or in its actual form, Prof. Osborne Reynolds has overlooked the fact that the machinery of Crookes's stress consists of a cooler as well as of the heater and intermediate gas, and that *a sufficient proximity of the cooler is essential.* Accordingly, the true expression for the force (of which I hope to publish an investigation made some time ago, as soon as my health will allow) is not so simple as Prof. Reynolds supposes, but is a function of the temperatures of the heater and cooler, and of the rate at which heat reaches the cooler by penetration, in addition to the single variable which one Prof. Osborne Reynolds admits. The vice of the mathematical reasoning, on which Prof. Reynolds bases his statement, is that it starts from a kinetic expression for the pressure of gas, which is only true when the mean of the squares of the velocities of the molecules is the same in all directions. Accordingly, his discussion does not reach the phenomenon it professes to explain; it is irrelevant to the case of compressed Crookes's layers, in which the gas is polarised, and where the degree of polarisation is itself a function of Prof. Reynolds's variable along with other thermal variables.

Thus, in all parts of his inquiry, Prof. Osborne Reynolds has been led into error by having regarded the gas of compressed Crookes's layers as gas in its ordinary state; in other words, because he has not had a glimpse of that peculiar molecular structure in the gas, which is the real source of Crookes's stress. From a review of the whole subject I think myself justified in submitting that the only discovery which brought with it any knowledge of the cause of Crookes's stress and of penetration, was the discovery that gas could assume this polarised condition; and I must say that it does not appear to me that to this discovery Prof. Osborne Reynolds has in any degree contributed.

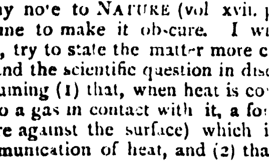
Dublin, November 15 G. JOHNSTONE STONEY

Postscript, November 23.—Prof. Osborne Reynolds has written a further letter to NATURE (vol. xvii. p. 61), in which he says:—"The fact that Mr. Stoney has in no way referred to my work, although I preceded him by some two years, has relieved me from all obligation to discuss Mr. Stoney's theory." I am sorry Prof. Osborne Reynolds should have thought me capable of discourtesy or inattention to the claims of a fellow-worker, and fortunately I am not conscious of being liable to the imputation. I became acquainted with Prof. Reynolds's paper in the interval between the publication of my first and second papers, but did not refer to it in my second paper because I found on reading it that Prof. Reynolds's explanations of Crookes's force were all erroneous (viz., the evaporation of mercury or other vapour, and heat communicated to diffused particles of gas, or to gas brought by convection currents); because the mathematical analysis with which he supports his hypotheses is irrelevant to the problem with which he is dealing; and finally, because for the purposes of my investigation I had no occasion to point out these mistakes, inasmuch as Prof. Reynolds had not approached the subject of polarised layers of gas and their mechanical properties, which was the subject matter of my papers.

I ought to add a word in reference to the criticism of my memoir on penetration, which is contained in Prof Osborne Reynolds's last letter. He seems to overlook a condition laid down in the second paragraph of my memoir, which disposes of the criticism, viz.: "Let us further regard this gas as *a perfect non-conductor of heat.*" Your mathematical readers will at once perceive that this condition is a legitimate simplification of the problem, because the diffusion or conduction of heat in gases is very sluggish compared with penetration, the phenomenon with which I was dealing.

IT appears from Prof. Osborne Reynolds's last letter that my wish to make my note to NATURE (vol xvii. p. 43) a fortnight ago short, led me to make it obscure. I will therefore, with your permission, try to state the matter more clearly.

As I understand the scientific question in discussion before us, it is this:—Assuming (1) that, when heat is communicated from a solid surface to a gas in contact with it, a force arises (equivalent to a pressure against the surface) which is proportional to the rate of communication of heat, and (2) that the conducting power of a gas for heat is independent of its density, Prof. Reynolds concludes that the driving-force on the vanes of a radiometer does not increase with the rarefaction of the air, but that rarefaction favours the motion only in so far as it lessens the opposing force due to convection-currents. I, on the other hand, while admitting Prof. Reynolds's premisses, do not admit his conclusion. On the contrary, I believe that, in the radiometer, rarefaction must increase the rate of communication of heat, and hence also the force. To see how this may be, let A B represent the thickness of a stratum of gas contained between two parallel solid surfaces, whose temperatures, measured from any zero, are represented respectively by A C and B D. Then, I imagine, the flow of heat through the gas will take place as *though* there were, in contact with each solid surface, a layer of gas whose temperature is throughout the same as that of the contiguous solid, and whose thickness is equal (or at least proportional) to the mean length of path of the molecules. The virtual thickness of the stratum of gas, whose conductivity comes into account in determining the rate of transmission of heat, is then the actual thickness diminished by the aggregate thicknesses of these two layers. For example, if A *a* and B *b* represent the thicknesses of the hot and cold layers respectively, the virtual



thickness of the stratum across which conduction takes place is *a b*, and the distribution of temperature from side to side of the whole quantity of gas is given by the ordinates of the broken line C*cd*D. If now the gas is rarefied, the mean length of path of the molecules, and consequently the thickness of each of the layers of uniform temperature, is increased, and the thickness of the stratum across which true conduction takes place is diminished. If, for example, the thicknesses of the layers become A*a'* and B*b'*, the thickness of the conducting stratum is reduced to *a'b'*, and the distribution of temperature is represented by the ordinates of the broken line C*c'd'*D. The rate of flow of heat in the two cases will be proportional conjointly to the inclination of the line *cd* or *c'd'* to AB, and to the conductivity of the gas; but as the latter factor does not vary with density, the result is proportional to the former only. It is evident that if this view of the matter is approximately correct rarefaction must increase the rate of transmission of heat across a stratum of gas whenever the increased length of path of the molecules, resulting from rarefaction, bears an appreciable proportion to the thickness of the stratum, but that it will have no sensible effect of the kind when the stratum of gas is very thick or the rarefaction itself very small.

I ought to acknowledge that precisely this mode of representing the effect of rarefaction occurred to me only as I was thinking how I could comply with Prof. Osborne Reynolds's wish that I should be "more explicit." When I wrote my last note I had in mind a somewhat different mode of action whereby it seemed that an equivalent result to that here pointed out would be brought about. The further consideration which Prof. Reynolds's letter in this week's NATURE has caused me to give to the subject has, however, led me to think that the view given above is not only clearer, but also a nearer approach to a correct representation of the facts than the one I had previously adopted. But apart from the accuracy of any particular explanation of *how* such a result can occur, the experimental evidence seems to me to prove conclusively that the force in the radiometer *does* increase (up to a certain point) with rarefaction. The action of convection currents depends to so great an extent on such conditions as the size and shape of the envelope and the position of the fly, and they must be so much disturbed as soon as the vanes begin to move, that if they played the essential part which I understood Prof. Reynolds to attribute to them, I cannot think that the effect of rarefaction would present anything like the degree of regularity that has been actually observed.

November 24 G. CAREY FOSTER

Mr. Crookes and Eva Fay

THE precise nature and grounds of the attestation given by Mr. Crookes to Eva Fay's "mediumship" appear in an article entitled "Science and Spiritualism" in the *Daily Telegraph* for March 13, 1875, embodying a communication made by Mr. Crookes himself to the *Spiritualist* of the preceding day.

The readers of NATURE will be able to judge for themselves by the following extracts from this article, whether Eva Fay was not fully justified in announcing her "mediumship" to the American public as having received Mr. Crookes's "endorsement."

"In the *Spiritualist* of yesterday, Mr. William Crookes, F.R.S., prints an account of a *séance* at his house in which Mrs. Fay exhibited some remarkable phenomena while under severe scientific conditions. The sitting took place on Friday evening, February 19, in the presence of several well-known men of science; and, on Mr. Crookes's suggestion, the medium was so placed as to form part of an electrical current connected with a galvanometer, indicating on a graduated circle the exact deflection produced by the current. In each hand Mrs. Fay held the terminal of a wire, and the fact that she kept continuous hold of the terminals was guaranteed by the amount of deflection of the galvanometer needle, and by the flashes of light which accompany each change of position or break of contact. This method was agreed to by the *savants* present, as affording absolute certainty that the medium could not remove her hand or body from the wires, whether in a trance or otherwise, without the fact being made known by the galvanometer. The sitting was held in a well-lighted drawing-room, the medium thus 'tied down by electricity' being screened by a curtain. What followed is thus described by Mr. Crookes:—

"We commenced the tests at 8.55 P.M.; the deflection by the galvanometer was 211 deg., and the resistance of Mrs. Fay's body 6,600 British Association units. At 8.56 the deflection was 214 deg., and at this moment a handbell began to ring in the library. At 8.57 the deflection was 215 deg. A hand came out of the cabinet on the side of the door farthest from Mrs. Fay."

A number of other occurrences of the like kind are then recorded; the hand reappearing from time to time, and presenting different members of the party with books and other articles severally appropriate to each, of which Mr. Crookes considered it impossible that Mrs. Fay could herself have gained possession.

He adds:—"Before Mrs. Fay came to the house that evening, she only knew the names of two of the guests who would be present; but during the evening the intelligence at work displayed an unusual amount of knowledge about the sitters and the labours of their lives."

The entire extract (which I should have reproduced in full if the space of NATURE had permitted) would show that—1. It *is* true that Mr. Crookes gave his *public attestation* to the genuineness of the so-called spiritualistic manifestations which occurred in his house through the "mediumship" of Eva Fay.

2. It *is* true that Eva Fay went back to the United States armed with Mr. Crookes's *public attestation* of the genuineness of the performances which took place at his house.

3. It *is* true that Mr. Crookes wrote a letter to a gentleman in the United States, giving a similar attestation, which letter was published in *facsimile* in an American newspaper.—*The only* thing that was *not* true in my statement, was that *(through having* mislaid the slip containing it) *I spoke of this letter as having been* addressed to Eva Fay herself, and having been written before her departure.

4. It *is* true that Eva Fay's *public* performances *in London* were imitated at the time by Messrs. *Maskelyne and Cooke;* and further, that her business agent *spontaneously offered* Mr. Maskelyne to expose (for a sum of money) the *tricks by* which she cheated "the F.R.S. people."—*If* NATURE *thinks it* worth while to admit into its columns the full particulars of that offer, Mr. Maskelyne is quite ready to furnish them. His general assertion of the fact has been long before the public ("Modern Spiritualism," p. 122), and has remained unchallenged, so far as I am aware, until now.

5. It *is* true that the whole *modus operandi* of Eva Fay's public "manifestations" in the United States has been publicly exposed in New York and Boston by Mr. Washington Irving Bishop, as stated in *Fraser's Magazine* for the present month.

It was not only in entire ignorance of these proceedings, but under the influence of a report in circulation among the Fellows of the Royal Society—that "Mr. Crookes had given up Spiritualism," that I expressed to Mr. Crookes, on the occasion of his receiving the Royal Medal, my desire to "bury the hatchet." But I most assuredly did not consider myself thereby pledged to keep silence in regard to any further proceedings of the like kind; and only learned at the beginning of the present year that Eva Fay had been trading on the "endorsement" given her by "Mr. Crookes and other Fellows of the Royal Society," which she naturally "improved" into that of "the Royal Society of England."

November 19 WILLIAM B. CARPENTER

Potential Energy

WILL you permit me to express a certain amount of scepticism as to the reality of Mr. O'Toole's troubles on this subject? That some statements made in the text-books quoted are not clear—that by an ingenious collocation of isolated passages from different authors some absurd conclusions may be drawn—we admit, but it may be doubted whether a Publius with the keen critical power of Mr. O'Toole would not be able to eliminate these errors or ambiguities by a reference to the context. In support of this position let us take the points raised by Mr. O'Toole in the order adopted by him.

A.—*Potential E., as meaning Energy* in posse.

The "doctors" quoted, with one exception, represent potential E.—not as energy *in posse*, but as kinetic energy *in posse*—a very different thing. Just as gold coin—though certainly not money *in posse*—may correctly be called silver coin (another form of money) *in posse.*

But it is said this name—and certain phrases employed by the doctors—imply that potential E. is "energy of about-to-supervene motion, or that it does not perform work except through the resulting E. of motion." Mr. O'Toole is so distressed because poor Publius is susceptible to this impression, that I feel some hesitation in asking what is wrong in it? How can work be done without motion? How can the potential E. of a system change without a change in the configuration—*i.e.*, motion of the system? Where is the mistake in the conception of potential E. continuously changing into kinetic energy, and this into work, as suggested by poor "P. M.," who was so summarily treated by this terrible O'Toole that I quake in my shoes as I think of my fate.

The exception mentioned above is an extract from Clerk Maxwell, which is certainly erroneous, and from which Mr. O'Toole gets a good deal of fun. We will not suggest that the addition of a single word would make the passage correct, for we should be told that text-books ought to be perfect. But it is only just to mention that the error occurs in an explanation of the name; in the definition of the thing the error does not occur; nay, it is expressly contradicted.

After this is it not unkind to condemn those doctors who drop the name "potential E." and replace it with such phrases as "E. of repose," &c., implying that the energy in question is not due to motion? By-the-by where is the bull in "passive energy"? and what is the "action" that may be confounded with kinetic energy?

B.—*Potential E. as meaning "Energy related to Potential Functions."*

The word Potential may be used in a second sense. This of itself is a trouble to Mr. O'Toole; but—remembering that your readers may not sympathise with his undisguised antipathy to verbal skylarking—he hastens to add that the two meanings are not only heterogeneous but incompatible. "Surely there is no occasion to stop to prove this." Please do, Mr. O'Toole; we should like to hear you prove something.

It may be noted that in this opinion and in paragraph 9 he appears to differ from Thomson and Tait. (See their definition of Potential, *Nat. Phil.*, vol. i., § 485).

C.—*Potential E. as meaning "Energy of Potency"*

It appears from a foot-note that "potency" may mean a force. If so, it is strange that the O'Toole—who, throwing off his thin disguise, at the end of his letter undertakes the "duty" of a doctor, and tells us that potential E. should be the "energy of a force"—it is strange that Dr. O'Toole should object to the name on this ground.

But the remarks under this head are chiefly interesting, as indicating the *modus operandi* of our pseudo-Publius. He does not trouble to examine the definitions of "potential energy." He only looks for explanations of the word "potential." Finding scant material in the doctor's utterances, he resorts to his dictionary, hunts up the different meanings of "potential," adds to these their antitheses, and rends his phantoms to pieces. It is scarcely a parody upon his letter to say—we won't trouble about what a civil engineer is, but let us examine the meaning of *civil*. Now civil has —— meanings: (A.) polite, (B.), &c. Therefore "civil E." means "polite E.," and "civil E." used as a *distinguishing* title cannot mean anything else than this, that the other E. is unpolite E.

As to the whereabouts of Potential Energy.

"We shall now pass from the perplexities connected with this unlucky name, 'potential E.,' to consider the behaviour of our teachers towards the thing itself." At last Mr. O'Toole will deign to discuss the definitions given by the doctors. Nay, he wanders away into an examination of such rash—but perhaps not inexcusable—phrases as "the potential E. of a raised weight," &c. The proper remedy for the troubles arising on this point is "to use words discreetly and consistently." But this is not sufficiently heroic. A local habitation must be found for this "potential E.," although it would seem as vain to inquire into the whereabouts of potential E. as into the whereabouts of Mr. O'Toole's scientific erudition. It is proposed to lodge this E. in the forces, and perhaps it won't do much harm, as we don't know where the forces are. It is proposed, moreover, to substitute "energy of tension" for "potential E." This done, the doctor's millennium will have come. Never mind about altering your conception of this kind of energy; call it by another name; give it a *weisnichtwo* lodging. There will be no more "confusion about fundamental principles;" there will be no more slips of the pen or tongue; there will be no more puzzled Publii; and last, but not least, there will be no more O'Tooles to bother the doctors. Well may "verbal skylarking" be despised. What is it beside such gigantic fun as this?

And yet I am sceptical. We started by hearing that it was "principally—though not entirely—the doctors who were to blame for this confusion about fundamental principles." Is this proved? Is not another cause indicated in the letter of of "E. G." (vol. xvii. p. 9)? And shall the doctors expect to be rightly understood when Dr. O'Toole's amanuensis admits (vol. xvi. p. 520) that Dr. O'Toole himself has been misapprehended upon almost every point by one reader at least?

Cirencester, November 13 H. W. LLOYD TANNER

Smell and Hearing in Moths

IN NATURE (vol. xvii. p. 72) your correspondent "E. H. K." observes: "'J. C.' seems to draw inferences that moths have not the power of smell, but have that of hearing. I feel quite certain they possess the former, but am in doubt about the latter. . . . .

"With reference to the sound of the glass, is it not the quick motion of the hand which disturbs the moth?"

May I draw the attention of both your correspondents to some experiments of mine on this subject which were published in NATURE about a year ago? These experiments, I remember, were quite sufficient to prove to me that moths have the power of hearing shrill notes; and, until I read the query of "E. H. K." above quoted, I thought that my account of these experiments must have been equally conclusive to any one who read them. On now referring to that account, however, I find that I there omitted to state one of the experiments which was resorted to for the purpose of avoiding the possible objection which "E. H. K." now advances. This experiment was a very simple one, consisting merely in making a sudden shrill whistle with my mouth by drawing the breath inwards, so as not to disturb the air in the neighbourhood of the insect. The latter, however, always responded to this as to other sounds in the way described, although throughout the experiment I took care not to move any part of my body.

GEORGE J. ROMANES

IT was because of my knowledge of facts like those named by "E. H. K." that I was surprised at the apparent inability of moths to smell ammonia. Being no physiologist, I ventured to draw no inferences; but it occurred to me to wonder whether the sense of smell differs in kind with different organisations; whether, for instance, some substances strongly odorous to us may be quite inodorous to insects, and *vice versâ*.

As to the experiment on hearing, I do not think it was the movement of the hand which startled the moths. It may conconceivably have been the vibration of their wings set up by the sound; but the experiment can easily be repeated with variations by any one interested in the subject. J. C.

Loughton

Meteorological Phenomenon

THIS morning at about a quarter before ten the sky here presented a most unusual appearance. The air was calm and the sun shining, but not brightly, through a slight veil of cirro-stratus. The sky was mostly covered with fibrous clouds of cirrus or cirro-stratus (I am not quite sure which I ought to call it), the fibres being quite parallel to each other, but in two different strata; those of one stratum were approximately from north-east to south-west, those of the other from north-west to south-east—so that they seemed to cross each other like the threads of a woven fabric. I think the fibres from north-east to south-west were the highest, but am not quite sure, though it seemed the same to another who was looking on with me.

JOSEPH JOHN MURPHY

Old Forge, Dunmurry, Co. Antrim, November 25

OUR ASTRONOMICAL COLUMN

STELLAR SYSTEMS.—M. Flammarion, in various notes communicated recently to the Paris Academy of Sciences, has been drawing attention to stars which appear to be affected with a common proper motion, or a motion similar in amount and in its direction. Several of his cases, however, are by no means to be styled "Nouveaux systèmes Stellaires." Thus the large and uniform proper motions of the southern stars ζ^1 and ζ^2 Reticuli, to which he refers in the *Comptes Rendus* of November 5, were the subject of remark in NATURE, vol. xi. p. 328. That there was a probability of a common proper motion in these stars would be evident to any one who inspected the columns in the British Association Catalogue, published in 1845, but as Taylor had not observed them, and the comparison was consequently dependent upon Lacaille and Brisbane only, there was a possibility of mistake. The first confirmation of the large proper motion of the B.A.C. in ζ^1 was afforded in Jacob's "mean places of 1440 stars"—from the Madras observations 1849-53, and

For 9 ι Ursæ Majoris ... $r = 52''\cdot5$ ... $\phi = 238^\circ\cdot9$
„ 10 „ ... $r = 52''\cdot6$ ... $\phi = 238^\circ\cdot5$

But, as we have stated, other similar cases are readily detected by an inspection of these columns. For instance: in γ and 58 Tauri, distant 35′, where $r = 13''$, $\phi = 97^\circ$; in 66 and 68 Draconis, distant 43′, $r = 13''\cdot5$, ϕ about 69° and for wider stars, in 26 and 34 Pegasi, distant 4° 25′, where $r = 30''$, $\phi = 84^\circ$; in η and 10 Arietis, distant 5° 11′, $r = 15''\cdot5$, $\phi = 86^\circ$, with other neighbouring stars, moving in nearly the same direction, and again in μ and 54 Aquilæ, distant 5° 13′, $r = 27''$, $\phi = 121^\circ$. The list might be largely increased.

It is nevertheless to be expected that the researches which M. Flammarion is so industriously following up with respect to stellar systems may lead to a considerable addition to our knowledge of them, in cases which are not thus easily discovered from existing catalogues, particularly by determining the proper motions of stars, not yet submitted to such investigation.

THE MINOR PLANETS.—A letter from Prof. Watson, of Ann Arbor, U.S., to M. Yvon Villarceau, dated November 5, deranges the ordinal numbers of the small planets given in this column last week, from No. 175 onwards. It appears that on October 1 he discovered a planet 10m., which he duly notified by telegraph to the Smithsonian Institution, but by some unexplained circumstance the information was not transmitted by cable to the Observatory of Paris, as usual with such discoveries. Supposing this object to be really a *new* planet, it will be No. 175, and the subsequent discoveries mentioned last week will be on the same supposition, advanced a unit. Elements of No. 172 appear in *Astron. Nach.*, No. 2,176, and of No. 176 in the Paris *Bulletin International* of November 25.

THE CORDOBA OBSERVATORY.—Within the last few days, Mr. John M. Thome, the zealous co-operator with Dr. B. A. Gould in the important astronomical work carried on for several years past at the Observatory of the Argentine Republic, has visited this country on his return to Cordoba from the United States. We have seen in his hands proofs of the charts of the Argentine "Uranometria," which are on a much larger scale than those of Argelander, Heis, and Behrmann. They have been engraved in New York. This work is expected to be soon published; also large lunar photographs taken at Cordoba. All the stars in the "Uranometria" have been meridionally observed.

presented to the British Association in 1832.

In 1842 Carl von Littrow succeeded his father as Director of the Observatory of Vienna, and the establishment has continued in vigorous activity under his charge. He has principally devoted the energies of the Observatory to equatorial astronomy, following up with diligence the observations of comets and planets, and with the aid of able assistants determining their orbits. Some of the most complete cometary discussions have emanated from the Observatory of Vienna while under his charge. The *Annalen der Sternwarte in Wien*, have been continued, and valuable astronomical work is contained in them, as for instance in the first volume of the third series, which appeared in 1851, where we have the positions of the stars in Argelander's Northern Zones reduced by Oeltzen to 1842, the epoch for which elements of reduction were given in the Bonn volume. Littrow was a frequent contributor to the publications of the Vienna Academy. In one of his memoirs—"Bahnnahen zwischen den periodischen gestirnen des Sonnensystems," printed in the *Sitzungsberichte* of the Academy for January, 1854, he applied an original process of investigation of the points of nearest approach amongst the orbits of the small planets discovered up to that time, and the orbits of the periodical comets—a troublesome work in which mechanical aid was introduced; the result was the discovery of many close approximations of planets with planets, planets with comets, and of comets with comets; amongst the latter near approaches of Biela's comet to the orbit of Halley's in 35° and 198° heliocentric longitude. When interest was excited relative to the expected return of the comet of 1556, which at that period was supposed to have been previously observed in 1264, Littrow was the means of bringing to light an unknown treatise by Heller, which, with the chart of Fabricius, has allowed of a much improved determination of the orbit, and similarly he made known interesting particulars with reference to the remarkable observation by Steinhebel and Stark of a rapidly-moving black spot upon the sun's disc on February 12, 1820. Littrow was a constant contributor to the columns of the *Astronomische Nachrichten*. The names of Hornstein, Oeltzen, Weiss, Schulhof, and others are well known in connection with the work of the Vienna Observatory during Littrow's direction. His death occurred on the 16th inst.

Von Littrow's wife, Auguste Littrow-Bischoff, is one of the best known Austrian authoresses of the present time. The genial qualities of the astronomer and his wife made them the centre of a large and admiring circle, and their residence was one of the most favourite gathering-places of the literary and scientific celebrities of Vienna.

BACTERIA[1]

IN a short paper communicated to the Royal Society at the close of last session, Prof. Tyndall did me the honour to criticise certain words reported to have been used by me at a meeting of the Association of Medical Officers of Health in January last. Although I am much indebted to him for the opportunity he has thus afforded me of discussing an important subject before this Society, I cannot refrain from expressing my regret that he should have thought it desirable to quote at length, and thus to place on permanent record in the Society's *Proceedings*, the expressions used on the occasion above mentioned. I regret this because these expressions occur in an abbreviated and incomplete abstract of a hastily prepared discourse not intended for publication.

As, however, I am well aware that Prof. Tyndall's purpose in his communication was not to criticise the language, but the erroneous views which the language appeared to him to contain, I shall make no further reference to the quotation; but shall regard it as the purpose of the present paper, first to reply to the reasoning embodied in his last communication, and secondly to corroborate certain statements previously made by me, to which he has taken exception in the more extended memoir published in the 166th volume of the *Philosophical Transactions*.

It will be my first object to enable the Fellows of the Royal Society to judge how far the views I entertain differ from those which have been enunciated here and elsewhere by Prof. Tyndall. Biologists are much indebted to him for the new and accurately observed facts with which he has enlarged the basis of our knowledge, as well as for the admirable methods of research with which he has made us acquainted. As regards the general bearing of these facts on the doctrine of Abiogenesis, I imagine that we are entirely agreed. So far as I can make out, the difference between us relates chiefly to two subjects, namely, the sense in which I have employed the words "germ" and "structure," and the extent of the knowledge at present possessed by physiologists as to the structure and attributes of the germinal particles of *Bacteria*.

Although Dr. Tyndall, in the title of his paper, refers to my "views of ferment," yet as he makes no further allusion to them, I will content myself with stating that in the passage quoted, the first sentence (from the words "In defining" to the word "living") has nothing to do with the following sentences, having been placed in the position which it occupies in the quotation by the abstractor. The paragraph ought to begin with the words "Ten years ago."

Of the meaning which attached itself to the word "germ" in the days of Panspermism a correct idea may be formed from the following passage from M. Pasteur's well-known memoir "Sur les Corps organisés qui existent dans l'Atmosphère." "There exist," says he, "in the air a variable number of corpuscles, of which the form and structure indicate that they are organised. Their dimensions increase from extremely small diameters to one-hundredth of a millim., 1·5 hundredth of a millim., or even more. Some are spherical, others ovoid. They have more or less marked contours. Many are translucent, but others are opaque, with granulations in their interior. . . . . I do not think it possible to affirm of one of these corpuscles that it is a spore, still less that it is the spore of a particular species of microphyte, or of another, that it is an egg or the egg of a particular microzoon. I confine myself to the declaration that the corpuscles are evidently organised; that they resemble in every respect the germs of the lower organisms, and differ from each other so much in volume and structure that they unquestionably belong to very numerous species." Such are the "germs" of M. Pasteur, and such is the conception of a germ which was entertained by informed persons up to 1870, and is very generally entertained up to the present moment.[1] It is obvious that these "corpuscules organisés" were, if they had any relation to *Bacteria*, not bacterium germs in Dr. Tyndall's sense, but "finished organisms," and yet it was of these that M. Pasteur said that it was "mathematically proved" that they were the originators of the organisms which are developed in albuminous liquids containing sugar, when exposed to the atmosphere.

With reference to the word "structure" I would point out that in the passage quoted from my lecture it is distinctly stated that the bacterial germ is endowed with structure in the molecular sense, but not in the anatomical sense. The meaning of the expression "anatomical structure" was, naturally, not defined, considering that the persons whom I was addressing might be supposed to be familiar with it. As, however, my failing to do so has apparently led to some uncertainty as to my meaning, I must, to avoid future misunderstandings, define more completely the difference between the two senses in which the word was used by me.

The anatomical sense of the word structure may be illustrated by referring to its synonyms, to the English words texture and tissue, to the Greek word ἱστίον, and to the German word *Gewebe*, from which two last the words in common use to designate the science of structure, viz., histology and *Gewebelehre* are made up. What I have asserted of the germinal particles of *Bacteria* is, that no evidence exists of their being endowed with that particular texture which forms the subject of the science of histology. In biological language there is a close relation between the words structure and organization, the one being an anatomical, the other a physiological term; either of these words signifies that an object to which it is applied consists of parts or structural elements, each of which is, or may be, an object of observation. As the observation is unaided or aided, the structure is said to be macroscopical or microscopical. The biologist cannot recognise ultra-microscopical structure or organisation except as matter of inference from observation, *i.e.*, from observing either that other organisms, which there is reason to regard as similar to the object in respect of which structure is inferred, actually possess visible structure, or that the object can be seen to possess structure at a later period of its existence. As instances in which the existence of structure is inferred the following may be mentioned:—The protoplasm of a Rhizopod is admitted to have structure because, although none can be seen in the protoplasm itself, the complicated form of the calcareous shell which the protoplasm makes or models can be seen. By analogy therefore other organisms which are allied to the Rhizopod are inferred to have structure, and from these, or from similar cases, the inference is extended to all kinds of cells, with respect to which it is taught by physiologists that although, in certain cases, no parts can be distinguished, the living material of which they consist is nevertheless endowed with structure or organisation. Similarly, we assume, that a *Bacterium* possesses a more complicated structure than we can actually observe, because in other organisms which are allied with it by form and life history, such complications can be seen. Again, in all embryonal organs we admit the existence of structure before it can be seen, because in the course of development we observe its gradual emergence. So far, inference of the existence of structure from historical evidence is justifiable; but if we were to carry this inference back to the ovum itself, and say that the characteristic structures of nerve, of muscle, or of gland, exist in the ovum at the moment after impregnation, every physiologist would feel the assertion to be absurd.

---

[1] "Remarks on the Attributes of the Germinal Particles of *Bacteria*, in reply to Prof. Tyndall," by J. Burdon-Sanderson, M.D., LL.D., F.R.S. Paper read at the Royal Society, November 22.

[1] Before I became aware that the contaminating particles of water are ultra-microscopical I myself was engaged earnestly in hunting for germs [illegible] in water and air. The search has been continued by others up to a much later period. Those who desire information on the organised particles of the atmosphere will find the subject exhaustively treated by Dr. Douglas Cunningham in a report entitled "Microscopical Examinations of Air," lately issued by H.M. Indian Government.

In the familiar comparison of the origin of the elephant with that of the mouse, in which the perfect anatomical similarity of the ova in the two species is contrasted with the enormous difference of the result, we should be justified in saying that the difference of development is the expression of structural difference between the primordium of the one and the primordium of the other; but inasmuch as it is not possible to indicate any anatomical distinction, it is understood that structural difference of another kind is meant, namely, difference of molecular constitution. In other words, we assume that the potential difference between the one and the other is dependent on an actual difference of molecular structure. Whether this is accompanied with an anatomical difference, such as we might expect to be able to see if we had more perfect instruments, we do not know.

From the moment that it is understood that the word structure means anatomical structure, the argument used by Dr. Tyndall loses its relevance. After referring to the "germ limit," he says, "some of those particles" (by which, I presume, is meant atmospheric particles) "develop into globular *Bacteria*, some into rod-shaped *Bacteria*, some into long flexile filaments, some into impetuously moving organisms, and some into organisms without motion. One particle will emerge as a *Bacillus anthracis*, which produces deadly splenic fever; another will develop into a *Bacterium*, the spores of which are not to be microscopically distinguished from those of the former organism; and yet these undistinguishable spores are absolutely powerless to produce the disorder which *Bacillus anthracis* never fails to produce. It is not to be imagined that particles which, on development, emerge in organisms so different from each other, possess no structural differences. But if they possess structural differences they must possess the thing differentiated, viz., structure itself." Throughout this passage it is evident that it is not anatomical but molecular structure that is referred to.

In the other passages relating to the subject, I venture to think that Dr. Tyndall has overlooked the distinction made by me between anatomical organisation and molecular structure. When, for example, he speaks of "germ structure" in the passage quoted from his Liverpool Address, he evidently refers to molecular structure exclusively, for he gives ice as his first example, and argues that as ice possesses structure so do atmospheric germs—a proposition which I should not have thought of questioning.

The experimental evidence which we have before us goes to prove that in all the known cases in which *Bacteria* appear to originate *de novo*—that is to say in liquids which are at the moment of their origin absolutely free from living Bacteria—they really originate from "particles great or small," which particles are therefore germs in the sense in which that word is used by Prof. Tyndall. To illustrate the views I myself entertain, and always have entertained on this question, I need only refer to my paper on the origin of *Bacteria*, published in 1871. The experiments made by me at that time brought to light the then new fact, now become old by familiarity, that all exposed aqueous liquids, even when absolutely free from visible particles, and all moist surfaces, are contaminated and exhibit a power of communicating their contamination to other liquids. As regards water and aqueous liquids in general, I insisted on the "particulate" nature of the contaminating agent, and coined for the purpose the adjective I have just employed (which has been since adopted by other writers), at the same time pointing out that the particles in question were ultra-microscopical, and consequently that their existence was matter of inference as distinguished from direct observation. Dr. Tyndall has demonstrated by the experiments to which I have already alluded, that the ordinary air also contains germinal particles of ultra-microscopical minuteness. Of the completeness and conclusiveness of those experiments I have only to express the admiration which I, in common with all others whose studies have brought them into relation with the subject, entertain. That such particles exist there can be no question; but of their size, structural attributes, or mode of development, we know nothing.

Prof. Tyndall, I am sure by inadvertence, has accused me of assuming that there is some relation between the limit of microscopical visibility and what he calls the molecular limit, by which I presume to be meant the size of the largest molecule. Nothing that I have said or written could justify such a supposition. My contention is not that the particles in question are of any size which can be specified, but, on the contrary, that we are not in a position to form any conclusion as to their size, excepting that they are so small as to be beyond the reach of observation. Dr. Tyndall has taught us, first, that the optical effects observed when a beam of light passes through a particulate atmosphere are such as could only be produced by light-scattering particles of extreme minuteness; and, secondly, that by subsidence these particles disappear, and that the contaminating property of the atmosphere disappears with them. He has thus approximately determined for us the upper limit of magnitude, but leaves us uncertain as to the lower; for we have no evidence that the particles which render the atmosphere opalescent to the beam of the electric lamp may not be many times larger than those which render it germinative. Consequently, the fact that the air may be rendered sterile by subsidence, while affording the most conclusive proof that germinal matter is not gaseous, leaves us without information as to the size of the particles of which it consists.

Of each germinal particle, whether inhabiting an aqueous liquid or suspended in the atmosphere, it can be asserted that under conditions which occur so frequently that they may be spoken of as general (viz., moisture, a suitable temperature, and the presence of dead proteid matter, otherwise called organic impurity), it produces an organism. If, for the sake of clearness, we call the particle *a* and the organism to which it gives rise A, then what is known about the matter amounts to no more than this, that the existence of A was preceded by the existence of *a*. With respect to A we know, by direct observation, that it is an organic structure; but inasmuch as we know absolutely nothing as to the size and form of *a*, we cannot even state that it is transformed into A, much less can we say anything as to the process of transformation.

Considering that it is admitted on all hands that there exist in ordinary air particles which are potentially germs, it might at first sight appear needless to inquire whether or not this fact is to be regarded as carrying with it the admission that they must necessarily possess the other attributes of organised structure. Very little consideration, however, is requisite in order to become convinced that this question stands in relation with another of fundamental importance in biology—that, namely, of the molecular structure of living material.[1] It is not necessary for my present purpose to do more than to indicate the nature of this relation. As regards every form of living matter, it may be stated that, quite irrespectively of its morphological characteristics, which, as we have seen, must be learnt by the application of the various methods of visual observation at our disposal, it possesses molecular structure peculiar to itself. We are certain of this, because the chemical processes of which life is made up are peculiar, that is, such as occur only in connection with living material. Even the simplest instance that we can mention, that of the elevation of dead albumin into living (a process which in the case now before us must represent the very earliest step in the climax of development) is at the present moment beyond the reach of investigation; for as yet we are only beginning to know something about the constitution of non-living proteids. But this want of knowledge of the nature of the difference between living and non-living material in no wise impairs the conviction which exists in our minds that the difference is one of molecular structure.

---

[1] The reader who is interested in this subject will find it discussed with great ingenuity by Prof. Pflüger, in his paper "Ueber die physiologische Verbrennung in den lebendigen Organismen," *Pflüger's Archiv*, vol. x. p. 300.

The sum of the preceding paragraphs may be stated in few words. Wherever those chemical processes go on, which we collectively designate as life, we are in the habit of assuming the existence of anatomical structure. The two things, however, although concomitant, are not the same; for while anatomical structure cannot come into existence without the simultaneous or antecedent existence of the kind of molecular structure which is peculiar to living material, the proof is at present wanting that the vital molecular structure may not precede the anatomical. At the same time it must be carefully borne in mind that there is no evidence of the contrary. It is sufficient for my purpose to have shown that the existence of organised particles endowed with anatomical structure in the "atmospheric dust" has not been proved. I do not dispute its probability.

Before leaving this subject I may be permitted to add a word as to the bearing of this discussion on a question which, to myself, is of special interest—that of *contagium vivum*. According to the view which these words are understood to express, the morbific material by which a contagious disease is communicated from a diseased to a healthy person consists of minute organisms, called "disease-germs." In order that any particle may be rightly termed a disease-germ two things must be proved concerning it, viz., first, that it is a living organism; secondly, that if it finds its way into the body of a healthy human being, or of an animal it will produce the disease of which it is the germ. Now there is only one disease affecting the higher animals in respect of which anything of this kind has been proved, and that is splenic fever of cattle. In other words, there is but one case in which the existence of a disease-germ has been established.

Comparing such a germ with the germinal particles we have been discussing, we see that there is but little analogy between them, for, first, the latter are not known to be organised; secondly, they have no power of producing disease; for it has been found by experiment that ordinary *Bacteria* may be introduced into the circulating blood of healthy animals in considerable quantities without producing any disturbance of health. So long as we ourselves are healthy, we have no reason to apprehend any danger from the morbific action of atmospheric dust, except in so far as it can be shown to have derived infectiveness from some particular source of miasma or contagium.

I now proceed to the second part of my communication, which relates to Prof. Tyndall's serious, but most courteously-expressed, criticisms of my experiments on spontaneous generation.[1]

The fact that Dr. Tyndall blames me for incautiously vouching for is, "that in boiled and hermetically-sealed flasks *Bacteria* sometimes appear in swarms." From multiplied experiments he concludes that this is not true, and infers that I who vouched for it was incautious. The paper referred to was one in which I, as a bystander, gave an account of certain experiments which Dr. Bastian performed in my presence. So far as relates to the fact above quoted, these experiments were, to my mind, absolutely conclusive; but inasmuch as I was unable to admit with Dr. Bastian that they afforded any proof of spontaneous generation, I followed them as soon as practicable by a series of experiments (NATURE, vol. viii. p. 141) (the only ones which I myself ever made on this subject), in which I tested the influence of two new conditions, viz., of prolonged exposure to the temperature of ebullition, and of exposure for short periods to temperatures above that of ebullition at ordinary pressure. The experiments accordingly consisted of two series, in the first of which a number of retorts or flasks charged with the turnip-cheese liquid, *i.e.* with neutralised infusion of turnip of the specific gravity 1017, to which a pinch of pounded cheese had been added, and sealed hermetically while boiling, were, after they had been so prepared, subjected to the temperature of ebullition for longer or shorter periods. In the second series the period of ebullition was the same in all cases, but the temperature was varied by varying the pressure at which ebullition took place.

The conclusion arrived at, as expressed in the final paragraph of the paper, was, that in the case of the turnip-cheese liquid, the proneness of the liquid to produce *Bacteria* can be diminished either by increasing the temperature employed to sterilise it, or if the ordinary temperature of ebullition be used, by prolonging its duration.

I did not think it necessary after 1873 to occupy myself further with the subject for two reasons, first, that I had accomplished my object, which was to show that as a ground for believing in spontaneous generation the turnip-cheese experiment was a failure; but secondly, and principally, because in the meantime the subject had been taken up by the most competent living observers, who had in every particular confirmed the accuracy of my results. I conclude this paper by referring shortly to some of these researches.

The first was made by P. Samuelson under the direction of Prof. Pflüger[1] in 1873. Its purpose was to ascertain whether it is true that certain liquids can be boiled for ten minutes without being sterilized, and secondly, to determine the influence of prolonged periods of exposure. The flasks employed were charged with the neutral turnip-cheese liquid, and sealed while boiling in the way already described. Some were subjected to the temperature of ebullition for ten minutes, the rest for an hour, the result being that whereas those heated for the longer periods remained without exception barren, an exposure of only ten minutes was followed, in the majority of cases, by an abundant development of *Bacteria*.[2] At about the same period a similar series of experiments was made under the direction of Prof. Hoppe-Seyler at Strasburg. The results were essentially the same.[3]

---

[1] The expressions referred to are the following:—"I have worked with infusions of precisely the same specific gravity as those employed by Dr. Bastian. This I was especially careful to do in relation to the experiments described and vouched for, I fear incautiously, by Dr. Burdon-Sanderson, in vol. vii. p. 180 of NATURE. It will there be seen that though failure attended some of his efforts, Dr. Bastian did satisfy Dr. Sanderson that in boiled and hermetically sealed flasks *Bacteria* sometimes appear in swarms. With purely liquid infusions I have vainly sought to reproduce the evidence which convinced Dr Sanderson. . . . . I am therefore compelled to conclude that Dr. Sanderson has lent the authority of his name to results whose antecedents he had not sufficiently examined." *Phil. Trans.*, vol. clxvi. p. 57. In the abstract of a lecture delivered at the Royal Institution, January 21, 1876, similar words occur, as also in a letter to NATURE, dated February 27, 1876, in which Dr. Tyndall, after remarking that the experiments of Dr. Bastian, witnessed by me, were too scanty and too little in harmony with each other to bear an inference, suggests that I should repeat them.

[1] "Ueber Abiogenesis," von Paul Samuelson aus Königsberg. *Pflüger's Archiv*, vol. viii p. 277. The paper is designated as a report of experiments made "im Auftrag und unter der Leitung des Geh.-Rath Prof. Pflüger." I refer in the text only to those experiments which were virtually repetitions of my own. The research actually extended over a wider field.

[2] "Als Resultat dieser Versuchsreihe, ergab sich eine massenhafte Entwickelung von Bacterien in den meisten nur 10 Minuten lang gekochten Flüssikeitsmengen nach 3–4 Tagen" (*loc. cit.* p 283).

[3] "Ueber die Abiogenesis Huizinga's," von Felix Putzeys aus Lüttich (aus dem chemisch-physiologischen Laboratorium des Herrn Prof. Hoppe-Seyler), *Pflüger's Archiv*, vol. ix. p. 391. In a note appended by Prof. Hoppe-Seyler to this paper he states that he has recommended its publica-

During the next year the second question which I had attempted to solve, viz., the influence of temperatures above 100° C., was taken up with much greater completeness by Prof. Gscheidlen, of Breslau.[1] After a *résumé* of the proofs already given by his predecessors, that certain fluids are not sterilised by boiling; and, secondly, that as means of sterilising such liquids the action of prolonged exposure and that of increased temperature may be regarded as complementary to each other, he proceeds to relate his own researches, the purpose of which was rather to fill up defects in the evidence than to establish new conclusions.

The flasks employed were capable of containing 100 cub. centims. (three and a half oz.); they were charged in the usual way with the turnip-cheese liquid, and exposed for short periods in chloride of calcium baths, of which the strengths were carefully adjusted so as to obtain the requisite temperatures. It was thereby definitely proved that whereas the germinal matter of *Bacteria* can stand a temperature of 100° for five or ten minutes it is destroyed by temperatures varying from 105° to 110°.[2]

In an appendix to my first paper, published in NATURE in the autumn of 1873, I showed that the solution of diffusible proteids and carbo-hydrates employed by Prof. Huizinga, of Groningen, in the first of the valuable series of experiments[3] published by him, relating to the subject of spontaneous generation, require a temperature above that of ebullition under ordinary pressure to sterilise them. This observation has since been established by Prof. Huizinga himself on the basis of very carefully made experiments,[4] by which he has proved at the same time that the liquids in question are rendered completely incapable of producing *Bacteria* without extrinsic contamination by exposing them to higher temperature. The only points of difference between us, either as regards method or result, are, first, that the sterilisation limit (Grenze zur Bacterienerzeugung) fixed by me was too low—the true limit being 110° C.—and secondly, that the experiments from which I had inferred that the liquids in question had been sterilised at lower temperatures than this were, in Prof. Huizinga's opinion, rendered inconclusive by the fact that my flasks were sealed hermetically, whereas in his exchange of air was allowed to take place during the period of incubation, through a septum of porous porcelain. To this last objection I might perhaps have thought it my duty to answer, had it not been shown by the subsequent researches of Gscheidlen to have no bearing on the question at issue. As regards the limit of sterilisation I can entertain no doubt as to the accuracy of Huizinga's measurements, and am quite willing to accept 108° C. as the lowest temperature which could be safely employed under the conditions laid down by him.

It will be understood that in bringing these facts before the Society my only purpose is to show, as I trust I have done conclusively, that the statements which Dr. Tyndall in 1876 characterised as incautious, and which he virtually invited me to retract, had been two years before confirmed in every particular by experimenters of acknowledged competence.

DIFFUSION FIGURES IN LIQUIDS[1]

In making some experiments on the mixture of liquids entering into another liquid at the extremity of a tube of small diameter, a phenomenon presented itself which attracted my attention as both new and singular. A certain quantity of coloured alcohol, remaining in suspension in the centre of a body of water, assumed, by spreading gradually out, a form resembling that of a shrub having its trunk and its branches terminated by leaf-like expansions. I sought to reproduce the phenomenon, believing at first that this mode of diffusion was purely accidental; but the phenomenon always recurring very nearly in the same manner, I devised a mode of experimenting which enabled me to study it more advantageously.

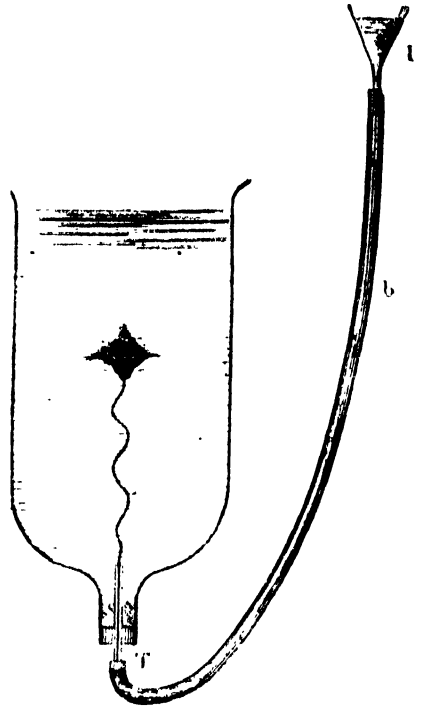


FIG. 1.—Apparatus of Prof. Martini.

C (Fig. 1) is a sort of cylindrical funnel of glass, to the neck of which is fitted a small capillary thermometrical tube T, about eight centimetres long. The capillary tube communicates by means of a caoutchouc tube *a b*, with a

---

tion notwithstanding that the results obtained were mere confirmations of those of former observers; adding "für den wissenschaftlichen Fortschritt hat nicht die Priorität des einen oder des anderen Beobachters, wohl aber die Zahl, Mannigfaltigkeit, und Zuverlässigkeit der Beobachtungen eine hohe Wichtigkeit."

[1] "Ueber die Abiogenesis Huizinga's," von Richard Gscheidlen, *Pflüger's Archiv*, vol ix p 163

[2] "Es folgt aus den eben angegebenen Versuchen, nach meiner Meinung, dass in Huizinga's Gemengen die Bacterien einer Temperatur von 110° 5 10 Minuten lang zu widerstehen vermögen, nicht aber einer von 105°-110° in ein geschmolzenem Glasröhre während der nämlichen Zeit" (*loc. cit.* p. 167) Here the author clearly fails to make the necessary distinction between *Bacteria* (which, as is well known, lose their vitality at a much lower temperature) and the material out of which they spring The mixtures referred to were either the cheese and turnip liquid or solutions containing peptones and grape sugar, to be immediately referred to. As affording an elegant demonstration that in the turnip-cheese liquid it is the cheese and not any other constituent which contains the resistant element, the following form of experiment is worthy of notice:—A tube A drawn out and closed at both ends is fused into the open mouth of a second tube B, of which the opposite end is drawn out and closed in a similar manner. In this way a compound tube is formed which is divided by a conical septum into two chambers A and B A small knob of glass having been previously introduced into the chamber B, the septum can be easily broken by shaking the tube With tubes so prepared two experiments are made. In Experiment 1, compartment A is charged with infusion of cheese, sealed, and then exposed to a temperature of 110° before it is united to the compartment B In like manner B is charged with neutral decoction of turnip, so that when the compound tube is complete it contains cheese in one compartment, turnip in the other If after boiling for ten minutes, it is placed in the warm chamber its contents remain barren. In Experiment 2 the experiment is varied by simply omitting the preliminary heating of A. The compound tube is boiled as before, but now its contents promptly give evidence that the conditions are present for an abundant development of *Bacteria*.

[3] Prof. Huizinga's papers on the Question of Abiogenesis are four in number. The references are as follows:—*Pflüger's Archiv*, vol. vii p. 225, vol. viii. pp 180, 551; vol. x. p 62

[4] The solution employed in these experiments was neutral, and contained, addition to the requisite inorganic salts, 2 per cent. of grape sugar, 0 3 per cent. of soluble starch, 0 3 per cent. of peptones, and 1 per cent. of ammonic tartrate As in my experiments, the flasks were heated in a Papin's pot, of which the temperature was 102° C. Even after half an hour's exposure to this temperature all the flasks became in two or three days "stark trübe und voll Bacterien," third paper, p. 555, January, 1874

[1] From an article in *La Nature* by Prof. Tito Martini, of Venice.

small funnel I, which may be raised or lowered at pleasure by means of its support. Pour into I a certain quantity of alcohol coloured say with a red solution of aniline. The liquid will traverse the capillary tube, from which it will flow unless prevented by compressing the india-rubber tube with a small pincers. This being done, fill with water the vessel C about three-fourths full; then by means of a funnel whose lower extremity reaches a little below the middle of the water, introduce a liquid denser than water, a concentrated solution of sea-salt or a thick syrup, until the vessel is filled up. Sulphuric acid may also be used, and in that case a less volume of liquid will suffice.

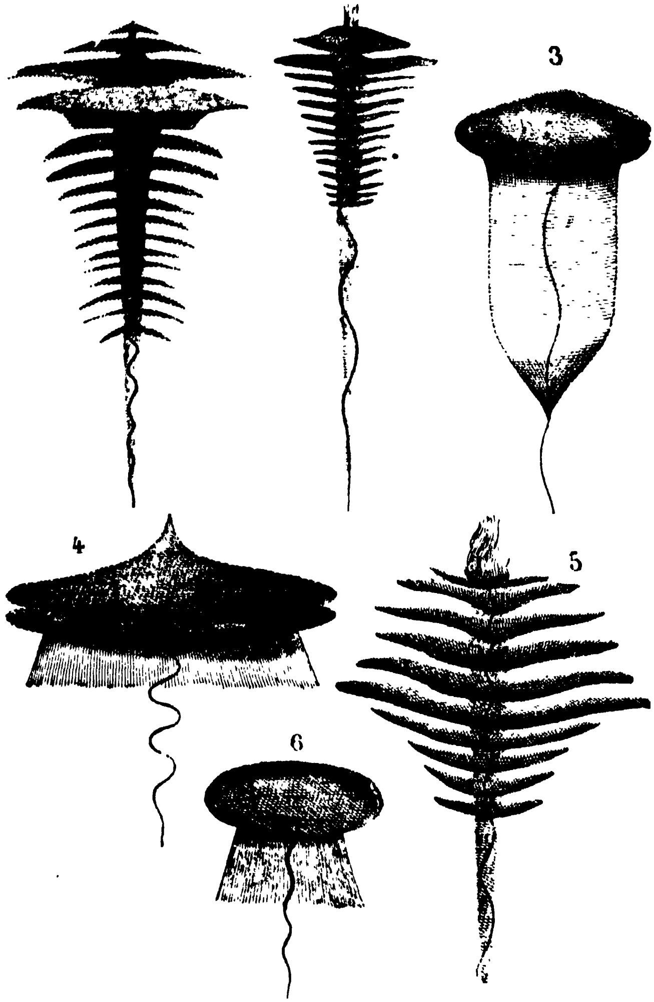

FIG. 2.—Experiments of Prof. Martini on the diffusion of coloured liquids in a sirupy liquid.

The liquid more dense than water will collect at the bottom of C; and there will thus be two layers of liquid superposed, the exact separation of which may be observed after being allowed to stand for an hour. If at the end of that time we raise the funnel I to a suitable height and relieve the pincers which compress the tube *a b*, the coloured alcohol which flows from the extremity of the capillary tube will enter the liquid in the vessel C, forming an ascending vein which usually has a spiral form. The alcoholic vein traverses the thickest layers of the liquid and is stopped at the boundary which separates the denser from the less dense part which floats above. At the point where the column of coloured alcohol is arrested, it will be seen to agglomerate into a mass at first formless; but, gradually, that mass elongates and extends, then is seen to throw out fluid threads in the form of foliage, sometimes similar to the petals of a flower, sometimes analogous to the leaves of a tree. After an hour the coloured alcohol has assumed a stable and regular figure. That figure varies in form with the liquids employed; it sometimes resembles a flower, sometimes a shrub, and sometimes it takes the form of a parasol of bright and vaporous colours, which add to its beauty.

The figure, so far as its form is concerned, attains its maximum of development three hours or more after the fluid vein begins to flow; but after that time the leafy expansions dilate more and more, and approach each other so as to form a mass of continuous layers, which remain suspended in the midst of the liquid. This happens even when the inflow has been arrested, either by applying the pincers to the india-rubber tube, or even by lowering suitably the funnel, I. It should also be remarked that around the vein of ascending liquid there very often forms a very fine tube, which assumes the aspect of the stalk of the flower, or rather the trunk of the liquid shrub; from different points of that stalk expansions in the form of leaves will be seen to proceed.

In order that the experiments I have devised may be successful, the tube through which the coloured liquid enters the vessel ought to be capillary, the flow ought to be gentle, and the apparatus maintained in a state of complete rest. It is necessary, moreover, to be careful first to expel the air from the india-rubber tube, since air-bubbles disturb the formation of the phenomenon. The following is a succinct *résumé* of some of the results I have obtained with different liquids:—

Colours of Aniline Solution.—I made use of aniline red, brown, green, and violet, dissolved in alcohol, being careful that the solution was not too concentrated. The forms obtained in sugared, salted, and acidulated water, are those represented in Fig. 2, Nos. 1 and 2. The figures obtained resemble, as will be seen, leaf-like expansions; the ramifications are turned downwards in sugared water (No. 1); in salt water, on the contrary, they are always raised, and at the commencement even more so than is shown in the figure. When acidulated water is used, the aniline colours are modified by the action of sulphuric acid; the green becomes pale yellow, the red becomes brown, and the violet acquires a beautiful green colour; but in all cases the shrub-like figure No. 2 is formed with perfect regularity.

Litmus. Aqueous Solution.—With this solution we obtain in acidulated water the figure represented in No. 3 (Fig. 2), which resembles a small parasol. Looked at from above, it has the aspect of a disc from the periphery of which proceed many equidistant rays very close to each other. In the salt water the same aqueous solution gives a different figure. In general, when aqueous solutions are employed to form the figures a space of time is required longer than that which is necessary in the case of alcoholic solutions.

Alcoholic Solution.—With this solution there are formed in salt or sugared water, figures analogous to Nos. 1 and 2; in acidulated water there is produced a shrubby appearance similar to No. 2.

Lake.—The aqueous solution of lake forms in salt water a figure similar to that of No. 4; in acidulated water Fig. 3 is produced, but more delicate and more regular than that obtained with litmus.

Azure Blue.—The aqueous and alcoholic solutions of azure-blue or pearl form figures similar to those already described. In acidulated water we obtain a very regular spheroidal nucleus of a very dark blue, surrounded by a spheroidal layer with an inferior stem (No. 6).

Cochineal.—The aqueous solution forms in acidulated water the figure No. 3, regular, like that of litmus and of lake. In salt water, cochineal, not being soluble, is precipitated and the phenomenon is not produced.

Iodine.—The alcoholic tincture of iodine forms, in sugared, salt, or acidulated water, beautiful figures almost identical with those of the colours of the aniline solution.

Bichromate of Potash.—To make the experiments with bichromate of potash succeed I changed the arrangement of the experiment on account of the very great density of the solution in comparison with the density of water. I fill the vessel in the usual manner, then I place above the vessel a small funnel, fitted with a capillary tube which partly enters the liquid. The aqueous solution of bichromate of potash being poured into the small funnel, flows out, forming a small descending spiral, which usually is arrested in the division between the more and less dense parts of the liquid. In acidulated or salt water two very beautiful figures are formed resembling those of Nos. 2 and 5, but reversed.

The various experiments described above have been repeated several times for each colour, and I have always obtained the same results. This persistence of form shows that the phenomenon is regulated by a law which I shall seek to discover. I believe I may conclude from these first attempts that the form of the figure depends on the liquid in which the colour is dissolved, more than on the colour itself. By employing other acids and other salts, not such, however, as precipitate the colour, it is probable that other figures would be obtained.

TRACES OF EARLY MAN IN JAPAN

So much interest is felt in the origin of the Japanese, that any information regarding earlier races in Japan will interest the readers of NATURE.

The discovery and examination of a genuine kjockkenmoedding, or shell heap, enables me to give positive evidences regarding a prehistoric race who occupied this island. Whether autocthonous or not it would of course be impossible to say. On my first ride to Tokio, in June of this year, I observed, from the car window, near a station called Omori, a fine section of a shell heap, which was recognised as such at once, from its resemblance to those I had often studied along the coast of New England. On September 16, accompanied by Messrs. Matsumura, Matsura, and Sasaki, three intelligent Japanese students, I made an examination of it, and a few days afterwards, in company with Dr. David Murray, Superintendent of Public Instruction, and Mr. Vukuyo, with two coolies to do the heavy digging, made an exhaustive exploration of it.

The deposit is composed of shells of various genera, such as Vusus, Eburna, Turbo, Pyrula, Arca, Pecten, Cardium, two strongly marked species of Ostrea, and curiously enough, *Mya arenaria*, not to be distinguished from the New England form, as well as other genera. These shells, so far as I know, still live in the Bay of Yedo. The heap is about 200 feet wide, and varies from a foot to five or six feet in thickness, with a deposit of earth above, at least three feet in thickness. It is now nearly half a mile from the shore of the Bay, though in accordance with the usual position of these heaps in other parts of the world, it must have been formed near the shore, and this fact indicates a considerable elevation of the land since the deposits were made. I may add that other evidences of a geological nature indicate a wide-spread upheaval in past times.

The peculiarities of the typical shell-heap, such as fragments of bones, rough implements worked out of horn, and pieces of pottery, are all here. The heap, however, is marked by certain features which render it peculiar.

First, the immense quantity of pottery and its diversity of ornamentation, some of it extremely ornate, but very rude.

Second, the absence of bone-implements, the few found—eight or ten in number—being of horn, with the exception of an arrow-head of diminutive proportions, made of the tusk of a wild boar. All the implements are very simple; two of them are like blunt bone awls, with the end very obtuse, and a constriction worked around the end. Another one is made from the natural termination of a deer's antler. A few fragments of horn were found which had been cut off at the ends.

Third, the entire absence of flint flakes, or stone implements of any kind, if we except a small stone adze found near the top of the heap, and made out of a soft sandstone. The frequent occurrence of isolated tusks of the wild boar would seem to indicate that these teeth were used for implements, and one piece of antler, having a hole in the end, is worked in the form of a rude handle. By far the most common bones found were those of the deer and wild boar, and curiously enough Steenstrup shows the same proportion in the Danish shell heaps. No human bones have yet been found.

An analysis of the red pigment found on some of the pottery shows it to be cinnabar. With its removal from the shore, its elevation above the level of the sea, the absence of stone implements, and the great thickness of the earth deposits above, we have reasons for believing that the deposit is of high antiquity.

Through the intelligent interest manifested by Mr. Kato and Mr. Hamao, Director and Vice-Director of the Imperial University of Tokio, every facility for a thorough investigation of these deposits will be given me.

Tokio, Japan, September 21 EDWARD S. MORSE

NOTES

It is proposed to hold the next annual meeting of the Association for the Improvement of Geometrical Teaching (under the presidency of Dr. Hirst) at University College, Gower Street, on January 11, 1878, at 10.30 A.M. Four resolutions are to be submitted to the Association:—1. That in the opinion of this Association it is both reasonable and expedient that candidates at all examinations in elementary geometry should be required to give evidence of such ability as is necessary for the solving of easy geometrical exercises; and that the secretaries of the Association be instructed to send a copy of this resolution to the leading examining bodies of the country. The other resolutions relate to the proposed formation of sub-committees for drawing up a syllabus of (1) Solid Geometry, (2) Higher Plane Geometry (Transversals, Projection, &c.), (3) Geometrical Conics. It may be in the recollection of our readers that the report of the British Association Committee (in 1876, published at the time in NATURE) was highly favourable to the work of this Association.

The dissection of the Berlin gorilla was performed last week by Prof. Virchow and Prof. Hartmann in the presence of several prominent Berlin physicians, and it was ascertained that the sudden death of the animal was caused by acute inflammation of the bowels, the same disease which carries off young children so rapidly. The dissection explains the cause of his previous illnesses and supplies valuable information with regard to the treatment of anthropoidal apes. The button of a glove, iron wire, and pins were found in Pongo's stomach.

DURING the past week the Emperor of Germany received a deputation of the members of the German Expedition for observing the transit of Venus, who presented him with a handsomely-mounted album containing copies of all the photographs taken during the transit.

BERN celebrates on December 12 the 100th anniversary of the death of its famous citizen, Albert Haller, who was equally renowned as physiologist, botanist, and poet.

THE New York *Nation* informs us that news has been received of the death of the Rev. James Orton, professor of natural history at Vassar College, and well known as the author of "Comparative Zoology" and "The Andes and the Amazons." Prof. Orton made his first expedition to South America in 1867, crossing the Andes eastward from Peru, and descending the Napo to the Marañon. His second expedition in 1873 was the reverse of the former one, beginning with the ascent of the Amazon. He was on his way home from a third expedition when he died, September 25, on board a small schooner on Lake Titicaca. He was greatly esteemed by all who knew him.

THE *New York Tribune* states that Mr. Edison, the inventor of many improvements in telegraphy, is hard at work in the endeavour to make the telephone record the sounds it transmits. His apparatus at present consists chiefly of a steel point attached to the disk of a telephone and pressing lightly on a strip of paper passed beneath the point at a uniform rate. The vibrations of the disk are thus recorded, and can be translated. Mr. Edison has already achieved some success in this attempt, but as yet finds difficulty with the more delicate vibrations. The invention suggests an ultimate possibility of recording a speech at a distance, verbatim, without the need of shorthand.

NOT one of the designs sent in in competition for the monument to Spinoza at the Hague has satisfied the judges. A new term for receiving designs will therefore be fixed.

ANOTHER letter from Mr. Stanley appears in the *Telegraph* of Thursday last, in which he gives many interesting details of his journey down the Lualaba-Congo, but does not add essentially to what we already know from previous letters. It will be well at present to rest satisfied with the fact that he has solved a great geographical problem; discussion will be appropriate and to some purpose when we are in possession of the full details. In the December number of Petermann's *Mittheilungen* that keen geographer discusses the bearings of Stanley's discovery, and on the basis of the earlier letters identifies the Lualaba-Congo with the discoveries of Browne, Barth, Nachtigal, and Schweinfurth; but on the map which accompanies the paper he carries the great river north to about 4° N. lat. In a postscript on Stanley's own map Dr. Petermann seems to think that his identifications may require modification. Dr. Petermann cannot find terms strong enough in which to speak of the merit of Stanley's work. He calls him "the Bismarck of African exploration," who has united the *disjecta membra* of previous explorations as Bismarck has made one great empire out of a number of isolated states. He is evidently inclined to place Stanley alongside of Columbus.

THE December number of Petermann's *Mittheilungen* contains a long paper on the Iquique earthquake of May 9 last, in which much valuable data are given on the earthquake and on the wave which was simultaneous with it over so wide a stretch of the Pacific Ocean.

THE *Daily News* correspondent at Rome writes that no news has arrived there as to the death of the African explorer, the Marquess Antinori, the inference being that he is still alive. A long letter has been received by the Italian Geographical Society from Signor Matteucci who, with Signor Gessi, is bound for Inner Africa; the two expect to be in Khartoum in the beginning of December. They were splendidly equipped before leaving Italy.

DR. SCHWEINFURTH, the celebrated African traveller, who has been staying at Berlin since the beginning of August, will shortly return to Africa, as he finds that the European climate no longer agrees with his health. At present he has left Berlin for Weimar.

AT the Geographical Society, on Monday night, Commander Musters, R.N., read a paper on Bolivia, in which he gave much valuable information about a country, its products and its people, about which we are extremely ignorant. Commander Musters lived in the country for a considerable time. Mr. Clements R. Markham read a paper on the still unexplored parts of South America. The facts is we are almost as ignorant of Central South America as, until recently, we were of Central Africa, and there is here a practically virgin field for a second Stanley, if not indeed for Stanley himself.

IN a recent number we referred to the preparations which are being made for Prof. Nordenskjöld's expedition to the Arctic regions next summer. The *Handels och Sjöfarts Tidning* of Gothenburg publishes further details, giving the plan of the expedition as presented to the King of Sweden by Prof. Nordenskjöld. We now learn that the steamer *Vega* is being fitted up at the royal wharves of Carlskrona, and will take provisions for two years. The Professor intends to leave at the beginning of July next, and his staff will consist of four scientific men besides himself, four Norwegian sailors who are well acquainted with the Arctic Sea, a ship's officer, eighteen marines, and a ship's doctor. The first halt will be made at the mouth of the Yenisei River; then the expedition will proceed to Cape Tscheljuskin, and try to penetrate as far as possible in a north-easterly direction.

MR. G. J. HINDE, of Toronto, Canada, writes us that a shock of earthquake, unusually severe for that part of the world, occurred along the valleys of the St. Lawrence and Ottawa Rivers, Lakes Champlain and St. George, and through New Hampshire, Vermont, and Western Massachusetts, at or near 2 A.M. of Sunday, the 4th instant. The limits along which it has been noticed are Pembroke on the Upper Ottawa to the north-west, Montreal on the east, Boston and Providence to the south-east, and Toronto to the west. The shock appears to have been most severe on the line of the Ottowa valley between Pembroke and Montreal, and between Ottawa city and Cape Vincent on the St Lawrence, following in a general direction the outcrops of the Laurentian range. It was but very slightly felt at Toronto, but at Montreal the shocks are stated to have lasted twenty seconds, and to have shaken movable articles about the rooms.

THE following grants in aid of researches have been made this year by the Committee of Council on the report of the Scientific Grants' Committee of the British Medical Association:—Mr. Gaskell, in aid of a research on the reflex action of the vascular system and muscles and reflex vasomotor action generally, 30*l.*; Mr. Langley, in aid of a research on the changes produced in the salivary glands by nerve influence, 25*l.*; Dr. Rutherford, F.R.S., for a continued research on the action of Cholagogues, 50*l.*; Drs. Braidwood and Vacher, for engravings for illustrating the third report on the life history of contagium, 40*l.*; Mr. Pye in aid of a continued research for the investigation of the relation that the retinal circulation bears to that of the brain, 8*l.* 15*s.*; Mr. Bruce Clarke, in aid of a continued research on syncope and shock, 10*l.*; Mr. A. S. Lee, Heidelberg, in aid of a research on the quantitative determination of digestive products obtained by the action of pancreatic ferment upon the various albumens, 25*l.*; Dr. McKendrick, Glasgow, in aid of a continued research into the antagonism of drugs, 30*l.*; Dr. McKendrick, Glasgow, in aid of an investigation into the dialysis of blood (renewed), 10*l.*; Dr. John Barlow, Muirhead Demonstrator of Physiology, Glasgow, in aid of an experimental investigation into the changes produced in the blood-vessels by alcohol, 10*l.*; Dr. Joseph Coats, Dr. McKendrick, and Mr. Ramsay, the committee upon the investigation of anæsthetics, 50*l.*; Dr. McKenzie, a research on pyæmia, 25*l.*; Mr. Callender, F.R.S., Dr. J. Burdon Sanderson, F.R.S., Dr. T. Lauder Brunton, F.R.S., and Mr. Ernest Hart, the committee appointed for the investigation of the pathology and treatment of hydrophobia, 100*l.* Total, 413*l.* 15*s.*

TELEGRAPH warnings are to be employed all over Paris for giving alarms of fires to all the fire-engine stations. The alarm is given by breaking a small pane of glass facing the streets, being a variation of the system employed on railways for signalling the engine-driver or guard.

IN the November session of the Berlin Geographical Society, Baron v. Richthofen was re-elected president. The evening was chiefly occupied by an address from Dr. Nachtigal, on the results of Stanley's lately accomplished expedition, which he regarded as the most prominent event among later African explorations. Prof. Orth gave a short description of a new method of cartography.

LIEUT. DE SEMELLÉ has intimated to the Paris Geographical Society that he intends to cross Africa from west to east, ascending the Niger and Binué, making for Lakes Albert and Victoria, and reaching the east coast at Mombasa or Malinda. He states that he has already obtained sufficient resources.

THE chemists of Berlin have been occupied lately in analysing the wares of the wine merchants, and no little excitement has been caused by the discovery that the entire stock of one of the largest houses dealing in wines for medicinal purposes, consisted entirely of artificially prepared mixtures of spirit and sugar solutions, flavoured with various herbs.

AT Leipzig a "General German Anti-Adulteration Society" has been formed, which has for its main object the prevention of the adulteration of food. A periodical is to appear, or has already appeared, as the organ of this society. At some fifty other German towns branch societies are being established. All political or religious matters are excluded from the programme of the society, while one of its statutes prescribes the special prosecution of the makers and sellers of so-called secret remedies and medicines.

IN evidence of the interest now being taken by Spain in scientific subjects we may draw attention to the *Boletin de la Institucion libre de Enseñanza* (Madrid, 1877), the first five numbers of which, from March 7 to June 17, now lie before us. We notice Geometria y morfologia natural, Prof. De Linares; Investigacion de los propiedades ópticas, Prof. Calderon; La religion de los Celtas españoles, Prof. Costa; Principios y Definiciones de la Geometria, Prof. Jimenez; Precipitacion de los metales puros por los sulfuros naturales, Prof. Quiroga. There are accounts of papers read at meetings under the headings "Resúmenes de Enseñanzas," and "Conferencias." The *Boletin* is in shape not quite so large as NATURE, and each number contains four pages.

THE Minister of Instruction in the cabinet chosen by Marshal MacMahon last week is M. A. E. A. Faye, the well-known astronomer, who is spoken of as Leverrier's probable successor. M. Faye is at present in his sixty-third year, and is chiefly known through his discovery of the comet named after him, in 1843. Since that time he has devoted his attention principally to the consideration of the problems of physical astronomy, the solar constitution, &c. His most important works are "Leçons de Cosmographie," 1852; and a translation of Humboldt's "Cosmos." M. Faye is probably the best known in what is ironically termed the *cabinet des inconnus*. French politics allure an unusually large number of scientific men. Naquet, the chemist, is now a leader of the radical wing of the Republican party, Dumas and Scheurer-Kestner are life members of the senate, and Wurtz was proposed as a candidate for the senate a few weeks since.

THE communication of the city of Moscow with the river Volga, leaving the railway out of account, was, up to the present, only possible in the spring of each year, on account of the shallowness of the Moskwa River. The boats were drawn by horses from Moscow to Kolomna on the river Oka, which falls into the Volga at Nishni-Novgorod, and this means of communication, on account of the great time it occupied, not to mention its cost, was a very imperfect one. A series of locks has recently been constructed on the Moskwa River, and tug steamers are now running between the capital and the Oka.

WE have already referred to the proposed introduction of the telephone into the German telegraphic service. Dr. Stephan, the enterprising Postmaster-General of the German empire, who has brought the German postal service to such efficiency, and fairly created the present international telegraphic system, appears to have definitely settled the question of the practicability of the general introduction of the new method. For the past few weeks the telephone has been in constant use between the General Post Office and the General Telegraph Office in Berlin, and has superseded the telegraphic communication between Berlin and some of the neighbouring villages. The results have been so satisfactory that a few days since a consultation of leading telegraphic officials was held to make arrangements for the establishment of a large number of telephonic stations. Since the equipment of these stations is so inexpensive, and the long and costly preliminary training of a telegrapher is avoided, it can easily be understood with what readiness the new invention is put into practical use. Interesting in this connection is the recent adoption of the telephone by Prince Bismarck. He has caused, as we stated last week, the establishment of a telephonic means of communication between the Chancellor's office in Berlin and his country residence at Varzin, in Pomerania, 230 miles distant; and finds that he is perfectly able to give instructions and receive reports without leaving his favourite castle. No subterranean wires, but the ordinary telegraphic wires on poles, are used for this purpose.

A SERIES of researches on the compressibility of liquids has recently been described by M. Amagat in the *Annales de Chimie et de Physique*. Among other results, the compressibility is found to be far from depending on the volatility of liquids, as might be supposed. The presence of sulphur, chlorine, bromine, and probably also iodine, tends to diminish the compressibility (a fact sufficiently explained by the corresponding increase of density). With regard to alcohols, the compressibility diminishes from the first member of the series, methylic alcohol, at least at 100°. At 14° common and methylic alcohol have nearly the same compressibility; and at zero the common alcohol is perhaps more compressible than methylic alcohol. Of the ethers, ethyl-acetic ether is more compressible at 14° and at 100° than methyl-acetic ether (an inverse order to that of the densities, which decrease as you rise in the series. With regard to hydrocarbons, the compressibility decreases regularly both at ordinary temperature and at 100° as you descend in the series.

A MICROSCOPICAL study has recently been made by M. Prillieux, of a disease of fruits, and especially of pears, which consists in the appearance of spots, then of crevices, issuing in complete disorganisation. From the facts described, it appears that the cause of this evil is a fungus, the spores of which are developed on the skin of the fruit with the appearance of a thin filament. At a certain time this filament penetrates the epidermis and produces a mycelium, which develops in the very mass of the fleshy tissue. Later there appear, in addition, fructiferous filaments, which bear about twenty-five spores each. The cells of the fruit, on passage of the parasite, are destroyed, and it is thus that the crevices are formed.

The diffusion which takes place between two gases separated from each other by an absorbent film (*e.g.*, a soap film) was studied a short time ago by Prof. Exner, of the Vienna Academy. He has recently extended his inquiry to the case of vapours from easily volatile liquids, using the same apparatus as for permanent gases. The experiments were made with sulphide of carbon, chloroform, sulphuric ether, benzine, alcohol, and oil of turpentine, and they show that the diffusion from such vapours follows the same laws as those of gases, *i.e.*, that it depends both on the coefficient of absorption of the film and on the density of the gas being directly proportional to the former, and inversely proportional to the square root of the latter. Thus it appears that the greater or less distance of a gas from its liquefaction point has at least no influence on this kind of diffusion.

It is reported that Herr Josef Albert, the eminent Munich photographer, has made the highly important invention of photographing the natural colours of objects by means of a combination of the ordinary photographic process with a photographic printing press constructed by the same gentleman some time ago. The images are stated to be so perfect that not the least improvement with the brush is required, as the finest shades of colours are faithfully reproduced. The secret of the invention is said to be based on the separation of white light into yellow, blue, and red rays, and in the artificial application of the same colours in the printing press. The first negative is taken upon a plate which is chemically prepared in such a manner that it only receives the yellow tints or shades of the object; this is then passed through the printing press, the roller of which is impregnated with a yellow colouring matter. On the print only the yellow tints reappear more or less distinctly; the object is then again photographed, and this time a negative is prepared which only receives the blue shades and tints; a second printing press has its roller impregnated with some blue colour, and the plate of course gives a print with only the blue tints reproduced. In the same manner a third print is obtained which only shows the red shades and tints. The final manipulation now consists in printing the three images upon the same plate, when the three colours intermingle and the natural colours and shades of the objects are obtained. We need hardly point out the enormous importance of this invention.

A pamphlet just published by the Director of the Paris National Library contains some interesting statistical data respecting one of the finest libraries in the world. It has been found that the library contains 86,774 volumes on catholic theology, 44,692 volumes on the science of languages, 289,402 volumes on law, 68,483 volumes on medicine, 441,836 volumes on French history, and 155,672 volumes of poetry. The works on natural science are not yet catalogued. During 1876 the library received no less than 45,300 *French* additions and purchased 4,565 foreign books.

The additions to the Zoological Society's Gardens during the past week include two Black-eared Marmosets (*Hapale penicillata*) from South America, presented by Miss Quain; a Black-backed Jackal (*Canis mesomeles*) from South Africa, presented by Capt. Fulton, s.s. *Taymouth Castle*; a Common Boa (*Boa constrictor*) from South America, presented by Miss Alice Leith; a Brown Tree Kangaroo (*Dendrolagus inustus*) from New Guinea, a Slow Loris (*Nycticebus tardigradus*) from Malacca, a River Jack Viper (*Vipera rhinoceros*) from West Africa, purchased; a Green Monkey (*Cercopithecus callitrichus*) from West Africa, deposited.

THE LIBERTY OF SCIENCE IN THE MODERN STATE[1]

II.

It is easy to say: "A cell consists of small particles, and these we call plastidules; plastidules, however, are composed of carbon, hydrogen, oxygen, and nitrogen, and are endowed with a special soul; this soul is the product or the sum of the forces which the chemical atoms possess." Indeed this is possible; I cannot judge of it exactly. This is one of those points which are yet unapproachable for me; I feel there like a navigator who gets upon a shallow, the extent of which he cannot guess. But yet I must say that before the properties of carbon, hydrogen, oxygen, and nitrogen are defined to me in such a manner that I can understand how, through their combination a soul results, I cannot admit that we are justified in introducing the plastidule soul into the educational programme or to ask generally of every educated man that he should recognise it as a scientific truth to such a degree as to operate with it logically, and to base his conception of the universe upon it. This we may really not ask. On the contrary, I think that before we designate such theses as the expression of science, before we say this is modern science, we ought first of all to complete a whole series of lengthy investigations. *We must therefore say to the schoolmasters, do not teach this.* This, gentlemen, is the resignation which in my opinion, those ought to exercise who deem such a solution in itself to be the probable end of scientific investigation. We can certainly not differ on that point for a moment, that if this doctrine of the soul were really true it could only be confirmed by a long series of scientific investigations.

There is a series of events in the field of the natural sciences, by which we can show, for how long certain problems are in suspense, before it is possible to find their true solution. If this solution is found at last, and found in a direction of which there was a presentiment perhaps centuries ago, it does not follow that during those times which were occupied only by speculation or presentiment the problem might have been taught as a scientific fact.

Prof. Klebs spoke of *contagium animatum* the other day, *i.e.* the idea that in diseases the transmission takes place by means of living organisms, and that these organisms are the causes of contagious diseases. The doctrine of *contagium animatum* loses itself in the obscurity of the middle ages. We have had this name handed down to us by our forefathers, and it is very prominent in the sixteenth century. Certain works of that period exist, which put down *contagium animatum* as a scientific dogma with the same confidence, with the same kind of justication, as nowadays the plastidule soul is set up. Nevertheless the living causes of diseases could not be found for a long time. The sixteenth century could not find them, nor could the seventeenth and the eighteenth. In the nineteenth century we have begun to find some *contagia animata* bit by bit. Zoology and botany have both contributed to them: we have found animals and plants which represent contagia, and a special part of the knowledge of contagia has been absorbed into zoology and botany, quite in the sense of the theories of the sixteenth century. But you will already have seen from the address of Prof. Klebs that the end of proofs has not yet ended. However much we may be disposed to admit the general validity of the old doctrine, now that a series of new living contagia have been found, now that we know cattle disease and diphtheria to be diseases which are caused by special organisms, still we may not yet say that now *all* contagia or even all infectious diseases are caused by living organisms. After it has appeared that a doctrine, which was formulated already in the sixteenth century, and which has since obstinately emerged again and again in the ideas of men, has at last, since the second decade of the present century, obtained more and more positive proofs for its correctness, we might really think that now it was our duty to infer, in the sense of an inductive extension of our knowledge, that all contagia and miasmata are living organisms. Indeed, gentlemen, I will admit that this conception is an extremely probable one. Even those investigators, who have not yet gone so far as to regard the contagia and miasmata as living beings have yet always said that they resemble living beings very closely, that they have properties which we otherwise know in living [illegible]ngs only, that they propagate their kind, that they increase and are regenerated under special circumstances, that, indeed, they appear like real organic bodies,—these men, nevertheless, have waited, and rightly, until the proof of their being living organisms was furnished. And thus caution commands reserve even now.

---

[1] Address delivered at the Munich meeting of the German Association, by Prof. Rudolf Virchow, of Berlin. Continued from p 74.

We must not forget that the history of science presents a number of facts which teach us that very similar phenomena may happen in a very different manner. When fermentation was reduced to the presence of certain fungi, when it was known that its beginning was closely connected with the development of certain species of fungi, then it was really very obvious to imagine that all processes related to fermentation happen in the same way; I mean all those processes which are comprised under the name of "catalytic," and which occur so frequently in the human and animal body as well as in plants. There were, indeed, some scientific men who imagined that digestion, which is one of the processes which closely resemble the fermentative ones, was brought about by certain fungi which occur frequently (in the special case of cattle the question has been practically discussed), and which were supposed to cause digestion in the stomach in the same way as the fermentation fungi cause fermentation elsewhere. We now know that the digestive juices have absolutely nothing to do with fungi. Much as they may possess catalytic properties, we are yet certain that their active substances are chemical bodies which we can extract from them, which we can isolate from their other component parts, and which we can cause to act in the isolated state free from any admixture of living organisms. If the human saliva has the property of being able to change starch and dextrine into sugar in the shortest time, and if every time we eat bread this new formation of "sweet" bread takes place in our mouth, then no fungus takes part in this nor any fermentation organism, but there are chemical substances which, much in the same way as it happens in the interior of the fungus, bring about chemical change in matter. We see, therefore, that two processes which are extremely similar, the one in the interior of the fermentation fungus and the other in the process of human digestion, are brought about in different ways; the same process in the one instance is connected with a certain vegetable organism, while in the other it takes place without any such organism and simply through a liquid.

I should consider it a great misfortune if we were not to continue in the same way as I have done now, to examine in each single case whether the *supposition* which we make, the *idea* which we have formed and which may be highly probable, is really true, whether it is justified *by facts*. With regard to this I would remind you that there are cases also amongst the infectious diseases where most undoubtedly a similar contrast exists. My friend, Prof. Klebs, will no doubt pardon me if I, even now, in spite of the recent progress which the doctrine of infecting fungi has made, still remain in my reserve, and that I only admit that fungus which has been proved by demonstration, while I deny all the other fungi as long as I do not hear of facts which attest them. Amongst infectious diseases there is a certain group which are caused by organic poisons—I will only mention one of them, which, according to my opinion, is very instructive—I mean the poisoning by a snake-bite, a very celebrated and most remarkable form. If this kind of poisoning is compared with those kinds of poisoning which are generally called infectious diseases (infection does not signify much else than poisoning), then we must admit that in the courses both cases generally take the greatest analogies exist. With regard to the course of the illness nothing would oppose the supposition that the total sum of phenomena which occur in a human body after a snake-bite, were caused by fungi which entered the body and which produced certain changes in different organs. Indeed we know certain processes, septical ones, for instance, where phenomena of a completely similar nature occur, and it cannot be denied that certain forms of poisoning by snake-bite resemble certain forms of septical infection as much as one egg resembles another. And yet we have not the least cause to suspect an importation of fungi into the body in the case of snake bite, while in the case of septic processes we, on the contrary, acknowledge and recognise this importation.

The history of our natural science has numerous examples, which ought always to cause us more and more to confine the validity of our doctrines in the most stringent manner to that domain only in which we can actually prove them, and that we do not by way of induction, proceed so far as to extend doctrines immeasurably which have only been proved for one or several cases. Nowhere the necessity of such a restriction has become more apparent than on the field of the theory of evolution. The question of the first origin of organic beings, this question which also forms the basis of progressive Darwinism, is an extremely old one. It is not known at all who first tried to find the different solutions for it. But if we remember the old popular doctrine, according to which all possible beings alive, animals and plants, could originate from a clod of clay—from a little clod under circumstances—then we ought to remember at the same time that the celebrated doctrine of *generatio æquivoca*, of epigenesis, is closely connected with it, and that it has been a common idea for thousands of years. Now with Darwinism the doctrine of spontaneous generation has been taken up again, and I cannot deny that there is something very seductive in the idea of closing the theory of descent in this way, and, after the whole series of living forms has been constructed, from the lowest protozoa upwards to the highest human organism, to connect this long series with the inorganic world as well. This corresponds with that direction to generalise, which is so entirely human, that it has found a place in the speculation of mankind at all times, backwards to the most obscure periods. We have the undeniable desire not to separate the organic world from the universe, as a something which is divided from it, but rather to insure its connection with the universe. In this sense it is pacifying if one can say, the atom-group carbon and company—this is perhaps speaking too collectively, but yet it is correct, since carbon is to be the essential element—therefore, this association, carbon and company, has at some special time separated itself from the ordinary carbon and founded the first plastidule under special circumstances, and continues to found it in the present. But in the face of this we must mention that all real scientific knowledge of the phenomena of life has proceeded in an opposite direction. We date the beginning of our real knowledge of the development of higher organisms from the day when Harvey pronounced the celebrated phrase, "Omne vivum ex ovo," every living being comes from an egg. This phrase as we now know, is incorrect in its generality. To-day we can no longer recognise it as a fully justified one; we know that, on the contrary, a whole number of generations and propagations exist without ova. From Harvey down to our celebrated friend Prof. von Siebold, who obtained the general recognition of parthenogenesis, there lies a whole series of increasing restrictions, all of which prove that the phrase, "Omne vivum ex ovo" was incorrect speaking in a general sense. Nevertheless, it would be the highest ingratitude if we were not to acknowledge that in the opposition, which Harvey assumed against the old *generatio æquivoca*, the greatest progress was made which has been made by science in this domain. Later on a great number of new forms were known, in which the propagation of the different kinds of living beings is going on, in which new individuals originate—direct separation, gemmation, metagenesis. All these forms, parthenogenesis included, are data which have caused us to give up every single (*einheitliche*) system for the generation of organic individuals. In place of a single scheme we now have a variety of data; we have no uniform system left by which we could explain once for all how a new animal being begins.

Generatio æquivoca, which has been disputed and refuted as many times, nevertheless faces us again and again. It is true that not a single *positive fact* is known which proves that *generatio æquivoca* has ever occurred, that spontaneous generation has ever taken place in such a way that inorganic masses, let us say the association carbon and company, have ever spontaneously developed into an organic substance. Nevertheless, I admit that if we indeed *want* to form an idea how the first organic being *could* have originated by itself, nothing remains but to go back to spontaneous generation. This is clear. If I do not want to suppose a creation-theory, if I do not want to believe that a special creator existed, who took the clod of clay and blew his living breath into it, if I want to form some conception in my own way, then I must form it in the sense of *generatio æquivoca*. *Tertium non datur*. Nothing else remains if once we say "I do not admit creation, but I do want an explanation." If this is the first thesis, then we must proceed to the second and say "Ergo, I admit *generatio æquivoca*." But we have no actual proof for it. Nobody has ever seen *generatio æquivoca* occurring in reality, and everyone who maintained that he had seen it, has been refuted, not by theologians indeed, but by naturalists. I mention this, gentlemen, in order to let our impartiality appear in the right light, and this is very necessary at times. We always have our weapons in ourselves and about us, to fight against that which is not justified.

I therefore say that I must admit the theoretical justification of such a formula. Whoever will have a formula, whoever says "I absolutely want a formula, I wish to be perfectly at one with myself, I must have a coherent conception of the universe," must either admit *generatio æquivoca* or creation; there is no other alternative. If we want to be outspoken we may indeed own that naturalists may have a slight predilection for *generatio æquivoca*. It would be very beautiful if it could be proved.

But we must admit that it is not yet proved. Proofs are still wanting. If any kind of proof were to be successfully given we would acquiesce. But even then it would have to be determined first, to what extent we could admit *generatio æquivoca*. We should quietly have to continue our investigations, because nobody will think that spontaneous generation is valid for the totality of organic beings. Possibly it would only apply to a single series of beings. But I believe we have time to wait for the proof. Whoever remembers in what a regrettable manner, quite recently, all attempts to find a certain basis for *generatio æquivoca* in the lowest forms of the transition from the inorganic to the organic world, have failed, should consider it doubly dangerous to demand that this ill-reputed doctrine should be adopted as a basis for all human conceptions of life. I may, doubtless, suppose that the story of the *Bathybius* has become known to nearly all educated persons. With this *Bathybius* the hope has again vanished that *generatio æquivoca* can be proved.

I think, therefore, that with regard to this first point, the point of the connection between the organic and the inorganic, we must simply own that in reality we know nothing about it. We may not set down our supposition as a certainty, our problem as a dogma; that cannot be permitted. Just as in the progress of the doctrines of evolution it has been far more certain, more fertile, and more in accordance with the progress of accredited natural science, to analyse the original single doctrine part by part, we shall also have first to keep apart the organic and inorganic things in the old well-known analysing way, and not to throw them together prematurely.

Nothing, gentlemen, has been more dangerous to natural science, nothing has done more harm to its progress and to its position in the opinion of nations than premature syntheses. While laying stress upon this, I would point out specially how our Father Oken was damaged in the opinion not only of his contemporaries, but also in that of the following generation, because he was one of those who admitted syntheses into their conceptions to a far greater extent than a stricter method would have allowed. Do not let us lose the example of the natural philosophers; do not let us forget that every time that a doctrine which has assumed the air of a certain, well-founded, and reliable one, of one which claims general validity, turns out to be faulty in its outlines, or is found to be an arbitrary and despotic one in essential and great points, then a great number of men lose their faith in science entirely. Then the reproaches begin—"You are not sure even yourselves; your doctrine, which is called truth to-day, is a falsehood to-morrow; how can you demand that your doctrine shall become the object of instruction and of the general consciousness?" From such experiences I take the warning that if we wish to continue to claim the attention of all we must resist the temptation of pushing our suppositions, our merely theoretical and speculative structures into prominence to such a degree that from them we would construct the conception of the whole remaining universe.

(*To be continued.*)

THE METEOR

A METEOR of unusual brilliancy was seen on the evening of Friday, the 23rd inst., from various parts of the kingdom. Mr. F. A. Buxton writing to us from Hertford states that he saw it two miles north of that town at 8.26 P.M. He says:—"I was attracted by its glare notwithstanding the moonlight, and saw it moving vertically downwards. I could not accurately observe its path, but it passed, nearly or exactly, over a small star, just visible in the moonlight, which I think is π Herculis, and disappeared suddenly before it reached the horizon, in about N.P.D. 60 and R.A. 16·40. By comparing notes with another observer (half a mile north of Hertford) it appears to have been visible much nearer the zenith than I had seen it; probably I saw the last 15° of its path. From the apparent slowness of its motion and complete absence of sound I gather that it was far off. My guess at the moment was fifty miles. In consequence of its brightness its apparent diameter was probably illusory. It attained two *maxima* of splendour, one about over the star named, the other at its disappearance. Scarcely any 'trail' was left; what there was almost immediately vanished."

Mr. T. Mellard Reade writes that he saw it from Blundell-sands, Liverpool, at 8.20 P.M. Looking up he saw a splendid broad streak of blue light terminating in a ball of red fire rushing across the sky in a north-westerly direction. The first flash seemed directly overhead; if so, Mr. Reade states, the meteor must have travelled through at least 45°. Shortly afterwards the moon being intensely bright and a shower coming on from the west, across the sea a most splendid "moon" rainbow made its appearance, finishing as a perfect arch of vivid colours with a second and a perfect bow above it.

Mr. W. B. Ferguson writes from Edinburgh that while walking down Princes Street about 8·25 P.M. he saw a most brilliant meteor which appeared to fall almost vertically and burst with great brilliance apparently just behind the castle. Its direction from where he observed it was 10° west of south.

Mr. C. H. Dance, writing from Manor House, Ardwick, Manchester, gives the time as 8h. 25m. P.M. Greenwich mean time. The meteor, he states, appeared to come from the constellation Cassiopeia, and after travelling in a direction a little to the west of north, finally burst behind a cloud about thirty degrees above the horizon. The apparent size of the meteor was considerably greater than that of Mars during the late opposition, and the light which it emitted was intensely bright and of a bluish-green colour, leaving a decidedly red impression on the retina. The period of visibility would be about five seconds, and the sparks in the train were also visible for some seconds.

Mr. Plant, the Curator of the Salford Museum, observed the meteor at the same time, visible to the north of Manchester.

Dr. S. Drew, of Sheffield, saw it at about 8.30 P.M. He gives the apparent diameter as two minutes; path, from the square of Pegasus to near Altair; motion, slow; shape, at first globular, afterwards elongated, with tail. It then appeared to break up. Colour, at first blue-green, afterwards ruddy; light, brilliant. He heard no sound accompanying the meteor, and from the absence of sound and slow apparent motion, he infers the real distance and size of the bolide to have been great. Dr. Drew was, at the time of observation, a little to the west of the town of Rotherham.

Several correspondents write to the *Times* describing what they saw of this remarkable meteor, for it is evidently the same body which has been seen by the various observers. The Liverpool correspondent of the *Times* saw it about 8·30. "A large ball of fire shot from the sky, exploding and throwing off innumerable variegated sparks as it descended in a northerly direction. The track of sparks gave the meteor the appearance of a brilliant comet with a long tail. Some spectators state that they heard the hissing noise made in its course, and others allege that it descended into the water near the bar of the Mersey with a great noise, sending up a column of steam and spray."

Mr. Donald Mackay saw it from Victoria Street, London, shortly before 8·30 P.M. "It travelled with great rapidity for about 20° from the zenith to the horizon, bursting in a white ball as large as twelve of the planet Mars in one, lighting up all the houses surrounding Victoria Street, the point of observation, and leaving a large tail behind of the shape of a spear-head, with all the colours of the rainbow in it."

The Rev. J. Hoskyns-Abrahall writes from Combe Vicarage, near Woodstock, that about 8.20 the northern sky was suddenly lighted up with a glow that outshone that spread over the south-eastern sky by a moon nearly full. "Looking northwards I saw a globular meteor of a pale orange colour descending perpendicularly. Its apparent size was scarcely less than that of the moon. Just above the slope on which I was, and seemingly not half a mile off, it burst into huge fragments, which flared forth with a fierce, lightning-like, reddish glare, and scattered sparks of surpassing splendour."

Mr. D. Aldred writes from Milford, Derby, to the same effect. He saw the meteor about six miles north of Derby, about 8.25. "It was almost due north, and travelling from the zenith to the horizon, the point of dispersion being about 45° above the north point of the horizon. In shape it was conical, the greatest breadth about one and a half times the diameter of the moon. It left a trail of considerable length, and the colours detached were of most remarkable brilliancy."

"R. M. C." writes from Cathedine, Brecknockshire, giving the report of two reliable witnesses who were walking in an [illegible]terly direction at 8.25 P.M. Looking back, the moon being at the time obscured by a cloud, they saw a ball of the most intense white light, "about the size of a cannon-ball," traversing a space between two clouds, leaving behind it a fiery track of red.

A Worcester correspondent gives the time as 8.20. He describes the colour as brilliant blue and orange, and behind was a streaming trail of brilliant sparks, which remained visible for a few seconds after the brighter light had disappeared.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIDGE.—At a Congregation on November 22, the University seal was ordered to be affixed to a letter of thanks to his Grace the Chancellor of the University for his munificent gift of a complete apparatus of scientific instruments for the Cavendish Laboratory.

A meeting of the members of the University to consider the propriety of securing a personal memorial of Dr. Darwin, was held on Monday in the combination room of Christ's College, the Rev. Dr. Cartmell, Master of the College, presiding. It was proposed by Prof. Humphry and seconded by Prof. Fawcett, "That it is desirable that the University should possess a personal memorial of Mr. Charles Darwin, LL.D." Proposed by Prof. Newton and seconded by Mr. Piele, of Christ's, "That the members of the University now present form themselves into a committee, with power to add to their number, for the purpose of collecting subscriptions from members of the University to carry out the foregoing resolution." Proposed by Prof. Liveing, seconded by Mr. J. W. Clark, "That Mr. A. G. Dew-Smith, of Trinity College, be treasurer and secretary to the committee, and be authorised to receive subscriptions." It was understood that the memorial should assume the form of a portrait, and about 75*l*. was subscribed in the room.

EDINBURGH.—The subscriptions to the Edinburgh University Extension Fund now amount to 82,000*l*., and Government has now promised to add 80,000*l*. to the amount on condition that 25,000*l*. is raised by public subscription, of which the sum of 10,000*l*. must be subscribed by December 31st next. The University Professors at Edinburgh have already contributed among themselves 5,360*l*. towards the additional 25,000*l*. required.

ST. ANDREWS.—Lord Selborne has been elected Lord Rector of this University. The students had much difficulty in getting any eminent man to allow himself to be nominated, and it was only on the day previous to the election that it was resolved to pit Lord Selborne against the Right Hon. Gathorne Hardy.

Prof. Alleyne Nicholson has been appointed Swiney Lecturer on Geology by the Trustees of the British Museum.

LEIPZIG.—Prof. Leuckhart, the newly-elected Rector of the University, was installed into the duties of the office on October 31, and delivered on the occasion an able address "On the Development of Zoology up to the Present Time, and its Importance." The students already number nearly 3,200, an attendance, as usual, far above that of any other German university.

AMSTERDAM.—The new University of Amsterdam has lately made a most flattering offer to Prof. Gegenbaur, of Heidelberg, which has, however, been declined.

BERGEN.—It is intended to establish a new university in the Norwegian town of Bergen. Eighty thousand crowns have already been subscribed towards this object.

SOCIETIES AND ACADEMIES

LONDON

Mathematical Society, November 8.—Lord Rayleigh, F.R.S., president, in the chair.—The following were elected to form the Council during the session:—President: Lord Rayleigh, F.R.S. Vice-Presidents: Prof. J. Clerk Maxwell, F.R.S., Mr. C. W. Merrifield, F.R.S., Prof. H. J. S. Smith, F.R.S. Treasurer, Mr. S. Roberts. Hon. Secretaries: Messrs. M. Jenkins and R. Tucker. Other members, Prof. Cayley, F.R.S., Mr. T. Cotterill, Mr. J. W. L Glaisher, F.R.S., Mr. H. Hart, Dr. Henrici, F.R.S., Dr. Hirst, F.R.S., Mr. Kempe, Dr. Spottiswoode, F.R.S., Mr. J. J. Walker.—Prof. Cayley made two communications, on the function $\phi(x) = \frac{ax+b}{cx+d}$ (a singularly neat expression was got for $\phi^n(x)$, the late Mr. Babbage had considered the matter in 1813), and on the theta functions.—Mr. Tucker read a portion of a paper by Mr. Hugh MacColl (communicated by Prof. Crofton, F.R.S.) entitled the calculus of equivalent statements. A short account of this analytical method has been given in the July and November numbers (1877) of the *Educational Times*, under the name of Symbolical Language. The chief use at present made of it is to determine the new limits of integration when we change the order of integration or the variables in a multiple integral, and also to determine the limits of integration in questions relating to probability. This object, the writer asserts, it will accomplish with perfect certainty, and by a process almost as simple and mechanical as the ordinary operations of elementary algebra.—The president read a paper on progressive waves. It has often been remarked that when a group of waves advance into still water the velocity of the group is less than that of the individual waves of which it is composed; the waves appear to advance through the group, dying away as they approach its anterior limit. This phenomenon seems to have been first explained by Prof. Stokes, who regarded the group as formed by the superposition of two infinite trains of waves of equal amplitudes and of nearly equal wave-lengths advancing in the same direction. The writer's attention was called to the subject about two years since by Mr. Froude, and the same explanation then occurred to him independently. In his work on "The Theory of Sound" (§ 191), he has considered the question more generally. In a paper read at the Plymouth meeting of the British Association (afterwards printed in NATURE), Prof. Osborne Reynolds gave a dynamical explanation of the fact that a group of deep-water waves advances with only half the rapidity of the individual waves. Another phenomenon (also mentioned to the author by Mr. Froude) was also discussed as admitting of a similar explanation to that given in the present paper. A steam launch moving quickly through the water is accompanied by a peculiar system of diverging waves, of which the most striking feature is the obliquity of the line containing the greatest elevation of successive waves to the wave-fronts. This wave-pattern may be explained by the superposition of two (or more) infinite trains of waves, of slightly differing wave-lengths, whose direction and velocity of propagation are so related in each case that there is no change of position relatively to the boat. The mode of composition will be best understood by drawing on paper two sets of parallel and equidistant lines, subject to the above conditions, to represent the crests of the component trains. In the case of two trains of slightly different wave-lengths, it may be proved that the tangent of the angle between the line of maxima and the wave-fronts is half the tangent of the angle between the wave-fronts and the boat's course.—Prof. Clifford, F.R.S., communicated three notes. (1) On the triple generation of three-bar curves. *If one of the three-bar systems is a crossed rhomboid, the other two are kites.* This follows from the known fact that the path of the moving point in both these cases is the inverse of a conic. But it is also intuitively obvious as soon as the figure is drawn, and thus supplies an elementary proof that the path *is* the inverse of a conic in the case of a kite, which is not otherwise easy to get. (2) On the mass-centre of an octahedron. The construction was suggested by Dr. Sylvester's construction for the mass centre of a tetrahedral frustum. (3) On vortex-motion. The problem solved by Stokes as a general question of analysis, and subsequently by Helmholtz for the special case of fluid motion may be stated as follows: given the expansion and the rotation at every point of a moving substance, it is required to find the velocity at every point. The solution was exhibited in a very simple form.

Zoological Society, November 6.—Mr. A. Grote, vice-president, in the chair.—A letter was read from Mr. R. Trimen, containing remarks on the African species of *Sarcidiornis*.—A letter was read from Mr. A. O. Hume, containing some remarks on Mr. Howard Saunders' recent paper on the Sterninæ.—The secretary exhibited, on the part of Mr. Geo. Dawson Rowley, an egg of *Pauxis galeata*, laid by a black female.—Prof. W. H. Flower, F.R.S., read a paper entitled "A Further Contribution to the Knowledge of the existing Ziphioid Whales of the Genus *Mesoplodon*, containing a Description of a Skeleton and several Skulls of Cetaceans of that Genus from the Seas of New Zealand."—A communication was read from Lieut.-Col. R. H. Beddome, containing the descriptions of three new species of reptiles from the Madras Presidency. These were proposed to be called *Oligodon travancoricum*, *Gymnodactylus jeyporensis*, and *Bufo travancoricus*.—A communication was read from the Marquis of Tweeddale, F.R.S., containing an account of a collection of birds made by Mr. A. H. Everett in the Island of Luzon, Philippines. Three new species were named *Megalurus ruficeps, Dicæum xanthopygium*, and *Oxycerca everetti*.—Mr. D. G. Elliott read some remarks on *Felis tigrina*, Erx., and its synonomy, showing that *F. mitis*, F. Cuv., and *F. macrura*, Pr. Max., are identical with that species.—Prof. Garrod, F.R.S., read a paper on some points in the visceral anatomy of the rhinoceros of the Sunderbunds (*Rh. sondiacus*).—A second communication from Prof. Garrod contained a note on an anatomical peculiarity in certain storks.—Mr. Edgar A. Smith read a paper in which he described some shells from Lake Nyassa, and a few marine species from the mouth of the Macusi River, near Quillimane, on the East Coast of Africa.—A communication from Dr. O. Finsch contained the description of a new species of petrel from the Feejee Islands, which it was proposed to name *Procellaria albigularis*.—A second communication from Dr. Finsch contained a report on the collections of birds made during the voyage of H.M.S. *Challenger* at Tongatabu, the Fiji Islands, Api, New Hebrides, and Tahiti.—Mr. Edward R. Alston read a supplementary note on rodents and marsupials from Duke of York Island and New Ireland. *Macropus lugens*, Alst., was shown to be a synonym of *Helmaturus brownii*, Ramsay, while Mr. Ramsay's *Mus. echimyoides* and *M. musavora* were respectively identical with *Mus. brownii* and *Uromys rufescens* of Alston.—A communication from Mr. L. Taczanowski contained a supplementary list of birds collected in North-Western Peru by Messrs. Jelski and Stolzmann. Two species were new, and proposed to be called *Rallus cypereti* and *Penelope albipennis*.

Cambridge

Philosophical Society, October 22.—A communication was read by Mr. Balfour, on the development of the vertebrate ovum. The points dealt with in this paper were (1) the nature of the stroma of the ovary, and (2) the relation of the permanent ova to the large cells of the germinal epithelium, named primitive ova by Waldeyer.

October 29.—Mr. Bonney read a paper on the rocks of the Lizard District (Cornwall). The author brought forward evidence to prove that the serpentine of this district was clearly intrusive among the hornblende schists.

November 5.—Prof. Clerk Maxwell communicated to the society an account of the unpublished papers of the Hon. Henry Cavendish, which contain his experiments in electricity.

Manchester

Literary and Philosophical Society, October 2.—Rev. William Gaskell, M.A., in the chair.—A case of flowering of *Chæmerops fortunei* (Hook) at Alderley, by Arthur W. Waters, F.G.S. The fact of *Chæmerops fortunei* (Hook) flowering so far north as near Manchester seemed to the author to be of sufficient interest to be worth mentioning to the Society.—Table of effect of movement of the surface of the globe on the shifting of the axis of the earth, by Arthur W. Waters, F.G.S.

Paris

Academy of Sciences, November 19.—M. Peligot in the chair:—The following papers were read:—Meridian observations of small planets at the Greenwich and Paris Observatories during the third quarter of 1877, communicated by M. Villarceau.—New remarks on the quantities of heat liberated by mixture of water with sulphuric acid, by M. Berthelot. He affirms that sulphuric acid always liberates the same quantities of heat whether it have been recently heated or kept a considerable time.—*Résumé* of a history of matter (fifth article), by M. Chevreul.—On the theory and the various manœuvres of the economising apparatus constructed at the dam of Aubois, by M. de Caligny.—On the use of refined neutral oils for lubrication of pistons in engines with surface condensers, by M. Allaire. Lime causes decomposition of neutral fatty matters and unites with their acids, the result being a greater deposit than if lime had not been used. Doubtless the deposit is oleate of lime instead of oleate of iron, and the boiler is preserved from attack; but the inconveniences in condensing engines are aggravated, for the condenser ceases to act as the tubes get covered. M. Allaire commends the use of refined neutral fatty matters which are undecomposable under the ordinary pressure of boilers.—Various observations on phylloxera, by M. Boiteau. The winter egg is deposited exclusively on the exterior of the stock.—Discovery of a small planet at Ann Arbor, by Mr. Watson.—General map of the proper motions of stars, by M. Flammarion. One result of this comparison is contradictory of some common views as to the distance of stars relatively to their order of brightness; for the greatest proper motions do not belong to the most brilliant stars, but indifferently to all sizes. Again, the author cannot support Bessel's and Struve's view that double stars are carried through space more rapidly than simple stars.—On the equation with partial derivatives of the fourth order, expressing that the problem of geodesic lines, considered as a problem of mechanics, supposes an algebraic integral of the fourth degree, by M. Levy.—New applications of a mode of plane representation of classes of ruled surfaces, by M. Mannheim.—On the laws which rule the order (or class) of plane algebraic curves, of which each point (or each tangent) depends at once on a variable point and tangent in a given curve, by M. Fouret.—Extract from a letter (mathematical) to M. Hermite, by M. Fuchs.—On the decomposition into first factors of the numbers $2^n \pm 1$, by M. de Longchamps.—Reproduction of orthose, by M. Hautefeuille. Orthose can be obtained by raising to from 900 to 1,000 deg. a mixture of tungstic acid and a very alkaline silico-aluminate of potash containing one equivalent of alumina to six of silica. The tungstic acid forms tungstate of potash, and the silico-aluminate is thus brought to the composition of orthose.—On the composition and industrial use of gases from metallurgical furnaces, by M. Cailletet. These gases, if suddenly cooled, are found to contain an important quantity of combustible principles which can easily be lit again and burnt by passing, *e.g.*, through a grate with burning fuel, and having their velocity diminished.—Formation of iodous acid by the action of ozone on iodine, by M. Ogier.—On the solubility of sugar in water, by M. Courtonne. A saturated solution of sugar at 12·5° contains 66·5 gr. per cent. of sugar; one at 45° contains 71 gr. per cent.—On the products of oxidation of camphor, by M. Montgolfier.—Note on the accessory discs of the thin discs in striated muscles, by M. Renaut. Muscular striation is formed of a succession of thick discs alone contractile, and of clear bands traversed each by a thin disc and two accessory discs similar to each other as regards form, and probably having similar functions.—A nalgesia obtained by the combined action of morphine and chloroform, by M. Guibert. A subcutaneous injection of chlorhydrate of morphine is made at least fifteen minutes before inhalation of chloroform.—On the causes of violet colour in oysters of the basin of Arcachon, by M. Descoust. The colour is found to be due to the presence of a small algal of the family of Rhodospermeæ and Florideæ. This becomes more abundant in time of drought, and probably acts by absorbing moisture.—On the migrations and metamorphoses of the taenia of shrew mice, by M. Villot.—On certain monstrosities of Asterocanthion rubens, by M. Giard.—On the embryogeny of the cestoides, by M. Moniez.—On the bismuth ores of Bolivia, Peru, and Chili, by M. Domeyko.

THURSDAY, DECEMBER 6, 1877

TECHNICAL EDUCATION

PROF. HUXLEY has seized the occasion afforded him by his promise to aid the Working Man's Club and Institute Union by contributing to their present series of fortnightly lectures, to state his opinion on a question which, as we have already informed our readers, has lately been exercising the minds of some of the most influential members of various city companies.

For some time past a joint committee, representing the most important among these bodies, has been endeavouring to obtain information as to the best means of applying certain of their surplus funds to the assistance of what is called technical education, and there is little doubt that a proposal for a huge technical university, made some time ago, and the discussion which took place in connection with that proposal, has had somewhat to do in leading to the present condition of affairs.

Prof. Huxley and some four or five other gentlemen have been appealed to by this joint committee to send in reports on what they consider the best way to set about the work, and it is from this point of view that Prof. Huxley's lecture is so important. It was not merely fresh and brilliant and full of good things, as all his lectures are, but is doubtless an embodiment of his report to the joint committee.

We are rejoiced, therefore, to see that Prof. Huxley is at one with the views which we have all along expressed in NATURE, namely, that, after all, the mind is the most important instrument which the handicraftsman, whether he be a tinker or a physicist, will ever be called upon to use, and that therefore a technical education which teaches him to use a lathe, or a tool, or a loom, before he has learned how to use his mind, is no education at all.

Prof. Huxley not only defined technical education as the best training to qualify the pupil for learning technicalities for himself, but he stated what he considered such an education might be, and how the city funds can be best spent in helping it on.

Besides being able to read, write, and cipher, the student should have had such training as should have awakened his understanding and given him a real interest in his pursuit. The next requirement referred to was some acquaintance with the elements of physical science—a knowledge rudimentary, it might be, but good and sound, so far as it went, of the properties and character of natural objects. The professor is also of opinion that it is eminently desirable that he should be able, more or less, to draw. The faculty of drawing, in the highest artistic sense, was, it was conceded, like the gift of poetry, inborn and not acquired; but as everybody almost could write in some fashion or other, so, for the present purpose, as writing was but a kind of drawing, everybody could more or less be supposed to draw. A further *desideratum* was some ability to read one or two languages besides the student's own, that he might know what neighbouring nations, and those with which we were most mixed up, were doing, and have access to valuable sources of information which would otherwise be sealed to him. But above all—and this the speaker thought was the most essential condition—the pupil should have kept in all its bloom the freshness and youthfulness of his mind, all the vigour and elasticity proper to that age. Prof. Huxley then went on to explain that this freshness and vigour should not have been washed out of the student by the incessant labour and intellectual debauchery often involved in grinding for examinations.

We gather from this part of the address—we shall refer to the others by and by—that so far as Prof. Huxley's advice goes we are not likely to see any great expenditure of the money of the ancient city corporations either in the erection of a huge "practical" university or in the creation of still another "Examining Board." How then does he propose to spend it?

Here we come to a substantial proposal, which Prof. Huxley may consider to be the most important part of his address. What is wanted, he considers, is some machinery for utilising in the public interest special talent and genius brought to light in our schools. "If any Government could find a Watt, a Davy, or a Faraday in the market, the bargain would be dirt cheap at 100,000*l*." Referring to his saying when he was a member of the London School Board that he should like to see a ladder by which a child could climb from the gutter to the highest position in the State, he dwelt upon the importance of some system by which any boy of special aptitude should be encouraged to prolong his studies, to join art and science classes, and be apprenticed, with a premium if necessary. In the case of those who showed great fitness for intellectual pursuits they might be trained as pupil-teachers, brought to London, and placed in some collegiate institution or training school. In this way the money of the guilds would be spent in aiding existing teaching systems, in which, on the whole, an enormous progress was acknowledged.

It is true the architects of London would not have the opportunity of immortalising themselves by erecting an imposing edifice, but, on the other hand, the influence of the Guilds might be felt whenever there was a handicraft to foster, or a potential Watt to be sought out.

We do not imagine that it is Prof. Huxley's idea that there shall be no local representation of the city's new activity and influence; the reference to the training of teachers, we fancy, and other remarks here and there, seem to point to some such institution as the École Normale of Paris, where the best and most practical scientific teaching could be carried on. Every one knows how much room there is for such an institution as this, but on this little money need be spent, so far as bricks and mortar are concerned, as little money is needed to equip such laboratories as are really meant for work.

There is an advantage in such lectures as these by no means limited to the expression of opinion on the part of the speaker. The slow and sure way in which science is taking a hold upon our national progress is well evidenced by the fact that the daily press can now no longer ignore such outcomes as these, and hence it is that they do good beyond the mere boundary of the question under discussion. They show the importance of, and foster interest in, the general question of intellectual and scientific progress.

The *Times* agrees in the main with the kind of education to be given, and holds that "What is needed is to give a man the intelligence, the knowledge of general principles, combined with the habits of correct observation and quick perception, which will enable him afterwards to master the technicalities of his art, instead of becoming a slave to them. No objection can be taken to the advice that, for this purpose, a lad, after learning to read, write, and cipher, should acquire some facility in drawing, and should be familiarised with the elements of physical science. The importance of the latter study for this particular purpose is, indeed, unquestionable, and even paramount, for a handicraftsman is dealing exclusively with physical objects in his work, and his skill in applying the processes of his craft will vary in great measure with his knowledge of the scientific principles on which they depend."

But we fancy that the *Times* writer does not look upon this scientific part of education quite as the lecturer does, for he proceeds to add: "There can be little doubt, for instance, that many of the perils of mining might be averted if the miners were alive to the scientific reasons of the precautions they are urged to adopt. Many an improvement, probably, which now escapes the eye of a man who adheres slavishly to the rules of his craft would occur to him if he were applying them with conscious intelligence."

The *Times*, however, considers that the school-time is too short for the languages, and curiously enough drives its point home by saying a harder thing about the Greek and Latin of our public schools than Prof. Huxley has ever done; while, on the other hand, the *Daily News* points out that Prof. Huxley this time may have raised a hornet's nest about his ears by the unduly reasonable tone of his demands.

The *Daily News* then adds:—"A man of science who does not demand that from the earliest age an hour a day shall be devoted to each of the ologies may be regarded as a traitor to his cause." For our part we know of no man of science who has ever made such a demand; and a careful examination of what men of science have said on this point for the last ten years will show that these extreme views to which reference is here made are not those of men of science at all.

It will be well also if the strong language used in connection with the multiple examinations of the present day brings that question well before the bar of public opinion. The *Times* is "sorry to see another flout thus inflicted, in passing, on that system of examinations which, like most good institutions, may do harm to the few, but is indispensable as a motive for work to the great majority." Prof. Huxley has expressed the views of most of the leading teachers in this country with regard to the effect of these examinations upon the students, and he might have referred to their reflex action on the examiner. Go into a company of scientific men, and observe the most dogmatic, the most unfruitful, and the least modest among them, you will find that this man is, as we may say, an examiner by profession. Speak to him of research or other kindred topics, he will smile at you—his time is far too precious to be wasted in discussing such trivialities; like his examinees, he finds they do not pay. The example set by Germany in this respect, both as regards students and professors, cannot be too often referred to, and there is little doubt that the love of science for its own sake which has made Germany what she now is intellectually, has sprung to a large extent from the fact that each young student sees those around him spurred from within and not from without. *Noblesse oblige.*

In point of fact so far as our future scientific progress is concerned the examination question is as important as that connected with the kind of education to be subsidised by the city guilds, and it is important, seeing that our legislators will, in the coming time, have to give their opinion on these subjects as well as on beer, vivisection, and contagious diseases, that in Prof. Huxley's language "by the process called *distillatio per ascensum*—distillation upwards—there should in time be no member of Parliament who does not know as much of science as a scholar in one of our elementary schools."

NORTH AMERICAN STARFISHES

Memoirs of the Museum of Comparative Zoology at Harvard College. Vol. v. No. 1. North American Starfishes. By Alexander Agassiz. With Twenty Plates. (Cambridge, U.S., 1877.)

THIS memoir consists of two parts. The first contains a history of the Embryology of the Starfish, which is substantially the same as that published in 1864 as Part I., Vol. v., of Prof. Agassiz's "Natural History of the United States." The author has, however, added notes on the points where additions have been made by subsequent investigations. The second part treats of the solid parts of some North American starfishes.

The plates accompanying the second part were intended to form part of one of Prof. L. Agassiz's volumes of "Contributions to the Natural History of the United States," and have been drawn for more than twelve years. The late Prof. Agassiz intended to add them as illustrating the anatomy of several of the more common American species.

Under these circumstances the memoir is wanting in the completeness that distinguishes some of the other Memoirs of this series, such as that "On the Ophiuridæ," by Lyman, and that "On the Echini," by Alexander Agassiz; but though the subject of the Starfishes as thus presented is incomplete, it is beyond a doubt that we have here a work of great value that will serve not only as illustrating a number of American species, and showing the systematic value of characters often almost completely overlooked, but as determining the homology of several genera not previously figured, and of which the details of the solid parts are fully given.

The arrangement of the star-fishes into families adopted does not materially differ from that given by Perrier in his revision of the group. No general list, much less a synonymic catalogue, as in the case of Echini, is given; and this because the number of species in the hands of Prof. Perrier, from the *Florida* dredgings, as well as those found by the *Challenger* expedition, have added a number of remarkable forms not yet wholly determined to the American starfish fauna.

The author reminds us that the transformations peculiar to the Echinoderms constitute neither a metamorphosis nor a case of alternate generation. The egg becomes the embryo larva. Nothing essential is lost during the process. No intermediate form comes into the cycle; the yolk becomes the larva, and this latter becomes the young Echinoderm; and this larva is, according to A. Agassiz, an Acalephian larva, reminding one somewhat of the twin individuals of free Hydroids as Diphyes, though adapted to the mode of development of the Echinoderms. The Echinoderm plutean form, with its mouth-stomach intestine, and with its water system originally forming a part of the digestive cavity, bearing as it would seem, about the same relation to the Ctenophoræ, which the Hydroid Polyps hold to the true Polyps. Therefore Agassiz cannot admit that the views so frequently urged and so generally admitted as to the separation of the Acalephs and Polyps as a distinct type (Cœlenterata) from the Echinoderms have any foundation in nature. He would therefore still retain the Radiate sub-kingdom with its three equivalent classes—Echinoderms, Acalephs, and Polyps.

Agassiz thinks G. O. Sars' idea that Brisinga is the living representative of the palæozoic starfishes rather too far-fetched, and he sees no very radical difference between Brisinga and such ordinary starfishes as Solaster and Crossaster, and he considers that if there has been a single ancestral Echinoderm, his primordial descendants early assumed different lines of development diverging to a great degree, and retaining their characteristics from the earliest-known geological period. E. P. W.

VOGEL'S "SPECTRUM ANALYSIS"

Practische Spectralanalyse irdischer Stoffe. Von Dr. Hermann W. Vogel (Nördlingen: C. H. Beck.)

THE aim of the author in writing this book may best be described in his own words. He says in the introduction:—

"The many excellent popular books on spectrum analysis confine themselves chiefly to descriptions of the great discoveries made by means of it; the chemical books only give short descriptions of flame reactions of alkalies and alkaline earths; they contain seldom a detailed account of the methods of observation, and still less a description of absorption spectra. The present work is intended to fill up this want, and to be a text-book to the student, and a reference book to the initiated."

Prof. Vogel is an authority on the absorption spectra of liquids and solids. Nearly half the book is given up to them, and we must add the better half. Here we find for the first time a connected account of all that has been done on the subject. Such an account is exceedingly valuable, and it brings prominently forward the gaps which have yet to be filled up. Prof. Vogel treats the subject chiefly from the chemical point of view, but those who take greater interest in the theoretical part will also find excellent information. So, for instance, the effect of the solvent on the absorption spectra of solutions is discussed. The spectra of colouring matters are given in detail, and the account of the effect of chemical reagents on them will be found exceedingly interesting. There is no doubt that this part of the book will be of great use to every worker on the subject.

We wish we could say as much of the chapter on emission spectra. As long as the author treats of the spectra of alkalies and alkaline earths, he is on safe ground, but when he comes to discuss the question of double spectra and the spectra of gases, he is confused and unintelligible. Led away apparently by a desire to do justice to every writer, he quotes approvingly the most divergent opinions, as if they could be consistently held at the same time. He is very fond of saying that a body has been proved to have two spectra but that one of them belongs to the oxide or to an impurity, which is the same as saying that he possesses two watches but that one of them belongs to his brother.

The author is throughout the book careless in his expressions, and this comes prominently forward in this chapter. What, for instance, can the student make of the following paragraph (p. 170)?—

"*A strong electric spark passing through air gives the spectrum of oxygen together with that of nitrogen.* Both together form the so-called spectrum of air. Only one spectrum of oxygen is known. *In dry pure air the spark only generates the spectrum of nitrogen.*"

The two statements in italics contradict each other as they stand. One of them is true for higher pressures, the other for lower pressures, but this the author has forgotten to add.

It must be said that the subject is a complicated one, and even those who are practically acquainted with all the experimental details would find it difficult to give a connected and clear account of it.

The first part of the book which treats of the optical principles involved in the spectroscope is apparently well written, and the student will find in it elementary proofs of some important theorems.[1] ARTHUR SCHUSTER

OUR BOOK SHELF

Nyassa; a Journal of Adventures whilst Exploring Lake Nyassa, Central Africa, and Establishing the Settlement of "Livingstonia." By E. D. Young, R.N. Revised by Rev. Horace Waller. With Maps. (London: John Murray, 1877.)

THIS is a thoroughly interesting narrative, brisk, fresh, and instructive. Mr. Young tells the story of the planting of a missionary station under the united auspices of the Presbyterian churches of Scotland, at Cape Maclear, on the south-west corner of Lake Nyassa. Mr. Young for the most part takes us over classic ground, by the Zambesi and Shiré, over ground familiar to readers of Livingstone's earlier and his latest travels. Mr. Young in his hardy little steamer the *Ilala*, surveyed the north end of Lake Nyassa for the first time, discovering on its north-east shore a magnificent range of mountains, rising to from 8,000 to 12,000 feet above the level of the lake, and which he named after his old friend Livingstone. On the opposite shore is a range of less elevation. The lake is marshy at the north end, subject to quite oceanic storms, its shores being marked by varied and most attractive scenery. The steamer caused tremendous consternation among the slave-trading Arabs, who seemed to feel that with the advent of a British steamer on the lake their occupation was gone. The settlement was successfully planted and is likely to be of service both as a centre of civilisation and of more minute exploration.

Britannia: A Collection of the Principal Passages in Latin Authors that Refer to this Island. With Vocabulary and Notes. By Thos. S. Cayzer, Head-Master of Queen Elizabeth's Hospital, Bristol. Illustrated with a Map and twenty-nine Woodcuts. (London: Griffith and Farran, 1878.)

THE title-page sufficiently describes the contents of this little volume. We think the idea of making such a collection a happy one, not only for scholastic purposes, but also for the use of those who wish to be able at any time easily to refer to any of the passages in Latin authors in which our island is referred to. Mr. Cayzer gives also translations of some of the chief references in Greek writers. We should think, if teachers and examiners could be persuaded to break through custom, the introduction of such a book into schools would add interest to the reading of Latin, and furnish, besides, the little fellows with a stock of valuable information. Most of the cuts are appropriate, several being old friends.

[1] As a personal question I may add that the remark attributed to me on page 198 was made by Mr. Stoney and only quoted by me.—A. S.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.]

The Colour-Sense of the Greeks

MR. GLADSTONE has shown that the language of Homer is an inadequate vehicle for conveying precise and nicely distinguished ideas of colour. Whether the nation that was content to describe colours so imperfectly was also incapable of subtle perception of tones of colour is clearly another question. Language does not keep pace with perception unless a practical or æsthetic necessity arises for expressing what is perceived in words to other people.

Practical necessity gives names to pigments and bright objects, such as flowers and precious stones, rather than to tones of colour; the æsthetic necessity that lies upon the artist to utter what he has felt will naturally lead to imitative expression sooner than to an expression that is merely symbolical. In other words an early race will learn to use colour with nicety for decorative and pictorial purposes before it develops the distinctions of language requisite for accurate word-painting.

That this was actually the case among the Greeks appears, I think, very clearly in a passage of Ion which is preserved to us in Athenæus Deipnos., Lib. xiii. cap. 81 (p. 603 *seq.*). Ion, who was a contemporary of Sophocles, describes an evening which he spent with the great tragedian in Chios. Sophocles, admiring the blushing face of a little boy who served the wine, quoted, with high approval, a line of Phrynicus:—

> "The light of love gleams on the purple cheek."

On this a certain pedantic grammarian breaks in—"In sooth, Sophocles, thou art skilled in poetry; but yet Phrynicus spoke not well when he called the cheeks of a beautiful person purple. For if a portrait-painter were to colour the cheeks of this boy with purple pigment he would no longer appear beautiful. It is not fitting to compare what is beautiful with what is not so." Sophocles laughs at the objection, and replies—"Neither, then, my friend, wilt thou be pleased with that line of Simonides which, to the Greeks, has appeared very well said:—

> 'The maiden sending forth her voice from her purple mouth;'

nor with the poet, when he says, 'golden-haired Apollo;' for if the painter made the hair of the god golden and not black, his picture would be less excellent. Nor wilt thou be pleased with him [Homer] who said 'rosy-fingered,' for if one were to dip the fingers in rose-colour, one would produce the hands, not of a fair woman, but of a dyer of purple." This retort produced a general laugh, and confounded the pedant not a little.

The Greeks, then, were perfectly aware of the insufficiency of the poetic vocabulary of colour; and accordingly they did not expect descriptive rendering of colour from the poet. This, it is plain, is a circumstance that must constantly be kept in view in any attempt to find in the poetry of the Greeks a measure of the development of their colour-sense.

Aberdeen, December 3 W. ROBERTSON SMITH

The Comparative Richness of Faunas and Floras Tested Numerically

IN his letter in NATURE, vol. xvii. p. 9, Prof. Newton has strongly brought out the absurdity of comparing districts of *very different areas* by the proportionate number of species to area in each. On this principle he shows that to be equally rich with the small island of Rodriguez, Madagascar ought to possess four times as many species of birds as exist throughout the whole world! It does not, however, by any means follow that the method thus exposed may not be of value in comparing regions of approximately equal area, as is the case with several of the primary regions, to determine the comparative richness of which Mr. Sclater first applied it. I have not Mr. Sclater's paper at hand, but it is my impression that he made no attempt to show—"that the proper mode of comparing the wealth or poverty of one fauna with another was to state the proportion which the number of species composing it bears to the area over which they range"—as Prof. Newton implies that he did, but that he merely adopted this method as the only one readily available for the comparison of his regions. Although I took the opportunity of making some corrections in the figures, I never committed myself to the principle; and I very soon afterwards found that it was not to be trusted. As, however, several later writers have made use of it without remark, it will be interesting to consider where the exact point of the fallacy lies, and with what modifications the method can be trusted to give useful and consistent results.

If we compare two islands of almost exactly equal areas, such as Ceylon and Tasmania, and find that the one has twice or three times as many species of mammals or birds as the other, it will be generally admitted that we express the fact correctly when we say that, as regards such a group of animals, the one is twice or thrice as rich as the other; and the same may be said of two countries or two continents of identical areas. For on the supposition that there is a general correspondence between the numbers of rare and common, of local and of wide-spread species in the two areas compared (and this seems probable), then the average number of distinct species to be met with on one spot, or to be seen during a journey of equal length, will be proportionate to the total number of species in the two areas. But now let us divide one of the two continents or islands which we are comparing into two or more parts. We know, as a matter of fact, that one-half the area will always contain much more than half the total number of species, while one-tenth of the area will contain immensely more than one-tenth of the species. To take an example: the county of Sussex is about one-eightieth part the area of the British Isles, yet it actually contains full two-thirds of the total number of flowering plants, both being estimated by the same flora (Babington's "Manual," fifth edition, British Isles 1,536 species, Sussex 1,059 species). If we now compare either Britain or Sussex with an *equal area* on the continent of Europe or North America, we may obtain an instructive estimate of the comparative richness of their respective floras; but if we compare *unequal areas*, and then endeavour to equalise them by getting the proportions of species to area, we shall obtain erroneous results, which will become literally absurd when the areas compared are very unequal.

The problem remains, how to compare unequal areas of which we possess the zoological or botanical statistics. We can only do so by equalising them, and this may not be so difficult as at first sight appears. For example, let us take the Palæarctic and North American regions, in which the species of birds are nearly equal in number, but the areas are as about seven to three. The number of the Palæarctic species have, however, been proportionately increased of late years, and if we take the western half of the Palæarctic region so as to include North Africa and Persia we shall have an area about equal to the Nearctic region, and a number of species perhaps one-sixth or one-eighth less, which will thus represent the comparative richness of these two areas. The eastern half of the region, including Japan and North China, is probably as rich as the western; while the intermediate portion is poorer in species. Combining these three portions, and taking the average, we should perhaps find the Palæarctic region about four-fifths or five-sixths as rich as the Nearctic, instead of less than one-half, as shown by the method of proportionate areas.

Whenever we know how many *peculiar* species any district contains, we can deduct its area from the total area of the region to be compared, and this number of peculiar species, from the fauna of the region; and by this means we may reduce two unequal regions to comparative equality. Again, all detached portions or islands should be omitted in estimating the comparative richness of regions, because they affect these regions very unequally. By adding Britain to Europe you increase the area without adding to the fauna, and thus make the region seem poorer; while by adding Madagascar to Africa, or New Zealand to Australia, you add to the fauna in a greater proportion than you increase the area, and thus make the region seem richer. For a fair comparison continents should be compared with continents, and islands with islands, and these should in every case be brought to an approximate equality of area by lopping off outlying portions with their peculiar species. We shall then get results which will be instructive, and which will afford us a true estimate of the comparative richness of different countries in the several classes of animals and plants.

ALFRED R. WALLACE

Mr. Crookes and Eva Fay

IN Dr. Carpenter's eagerness to show that his statements about Mr. Crookes and Eva Fay had some basis of fact, he seems entirely to have forgotten the real issue which he has himself raised, and which is of great importance to all engaged in the study of these tabooed subjects. The question simply is, whether *any* investigation of the alleged abnormal powers of individuals, however painstaking and complete it may be, and however decisive its results, is to be branded with opprobrious epithets, without any proof of error or fallacy, but merely on the dicta of newspaper writers and alleged "exposers."

In the case before us Mr. Crookes made certain experiments in his own laboratory, in which the greatest refinements of modern electrical science were employed; and of these he published a detailed account. That is the sum total of his acts and deeds in regard to Eva Fay. Yet because these experiments have been referred to in America as indorsing Eva Fay's remarkable powers, and because some persons charge her with being an impostor, and go through an alleged imitation of her performances, Dr. Carpenter accuses Mr. Crookes of encouraging "disgraceful frauds" and indorsing a "notorious impostor." Now it is clear that, to support this accusation, Dr. Carpenter must *prove* that Eva Fay was an impostor in respect to what happened *in Mr. Crookes's house*, and that, to use Dr. Carpenter's own words, she evaded his "scientific tests" by a "simple dodge." He must prove that Mr. Crookes exhibited culpable carelessness or incapacity in accepting, as conclusive, tests which were really fallacious; for, otherwise, how can Mr. Crookes be held responsible for anything which happened afterwards in America? Dr. Carpenter has promised to do this in the forthcoming new edition of his lectures; but as the accusation against Mr. Crookes has been made in the pages of NATURE, and the question is a purely scientific one—that of the absolute completeness of the test of "electrical resistance"—I call upon Dr. Carpenter to explain fully to the readers of NATURE the exact particulars of that "simple dodge" which is to destroy Mr. Crookes's reputation as a physical experimenter, and to sustain the reputation of his accuser. Unless the explanation is so clear and conclusive as to satisfy *all* the witnesses of the experiments that Eva Fay *did* evade the scientific tests, and that what they saw was simple conjuring, then Dr. Carpenter is bound to find a conjuror who will submit to the same tests as Eva Fay did, and produce the same phenomena before the eyes of the witnesses, so as to show "how it is done." Mr. Maskelyne, who professes to have exposed Eva Fay, will of course be ready to do this for an adequate remuneration, which I feel sure will be forthcoming if Dr. Carpenter is proved to be right and Eva Fay's "simple dodge" is clearly explained.

I have already shown (in this month's *Fraser*) that the supposed *exposure* of Eva Fay in America was no exposure at all, but a clumsy imitation, as will be manifest when it is stated that the exposer, Mr. Bishop, performed all his tricks by *stretching the cord* with which his hands were secured to the iron ring behind his back! There is hardly a greater exhibition of credulity on record than Dr. Carpenter's believing that *such a performer* proved Eva Fay to be an impostor and Mr. Crookes's experiments valueless. But what can we expect when we find a *Daily Telegraph* report quoted as an authority in a matter of scientific inquiry?

I venture to think that, whatever may be their opinions as to the amount of *fact* in the phenomena called "spiritualistic" (by Dr. Carpenter, but never by Mr. Crookes), all men of science will agree with me that Dr. Carpenter is bound to *prove by direct experiment* that Mr. Crookes and his coadjutors were the victims of imposture on the particular occasion referred to; or if he fails to do this, that he should in common fairness publicly withdraw the injurious accusations he has made against Mr. Crookes and all who are engaged in similar investigations. If this is not done it is equivalent to deciding that no *possible* proof of such phenomena is admissible—a position which is not that of Dr. Carpenter, or, as far as I am aware, of the scientific world generally.

I beg to take this opportunity of apologising for my involuntary appearance under false colours in this month's *Fraser*. The letters "F.R.S." were added to my name after the corrected proofs left my hands and wholly without my knowledge. I have desired the editor to make a statement to this effect in his next issue, but in the meantime wish to set myself right with the readers of NATURE.

ALFRED R. WALLACE

Nocturnal Increase of Temperature with Elevation

WITH reference to the article in NATURE, vol. xvi. p. 450, on the above subject, allow me to place on record the following facts. On the night of January 7, 1874, in Lucknow, the temperature fell considerably below the usual. The minimum thermometer on the grass at the observatory registered 5° below freezing point. The destruction of plants in the Horticultural Gardens was great. Plantains, pine apples, sugar-cane, mango trees, casuarinas, pomsettias, colvilleas, bugainvilleas, &c., &c., were all injured; some killed outright. The remarkable fact which I observed on that occasion was, that the destruction of vegetation was only up to a certain height, viz., up to between seven and eight feet from the ground. Above that, not a leaf was touched by the frost. On the mango trees especially, which were planted close to each other, it was very remarkable to see a distinct line of destruction along the trees, of seven or eight feet from the ground. This, I think, distinctly showed that the temperature on that night, above eight feet from the ground, was decidedly warmer, and thus protected all vegetation, while all below it was more or less injured, or killed by frost. Other observations, I made lately, corroborate the result of the direct observations made by Mr. Glaisher. During the commencement of October there were several rainy days, with an easterly wind; the total rainfall was under 2½ inches. When it ceased, and the clouds cleared away, I observed the following:—Before seven o'clock in the morning there were only a few low-lying clouds to be seen. As the sun rose, the wind still in the east and almost a calm, clouds began to form in all directions; about noon, and till about 3 P.M., the sky was thickly studded with cumuli of various sizes. After that hour, wider and wider gaps began to form between the clouds, and the dissolving of the cloud-masses continued as the sun approached setting. About two hours after sunset there was scarcely a cloud to be seen, and the twinkling stars came out in their full brilliancy. This melting of the clouds after a certain hour, and completely so after sunset, would, I think, indicate that the cloud region after sunset became decidedly warmer than it had been during the day.

E. BONAVIA

Lucknow, October 22

Expected High Tides

MR. EDWARD ROBERTS in his letter has, I think, missed the chief object I had in addressing you. I did not complain that the authorities had not taken pains to calculate the heights of the tides, but that while one could take up almost any paper on the coast and find the heights of the tides of the place for the coming week, not one of the London papers, so far as I could find, supplied this information for its readers. What I felt to be a desirable thing was that the Meteorological Office, or some other constituted authority, should send to the daily papers warnings, when necessary, that on such a day a dangerous tide might be expected with a wind from such a quarter and with such a barometer, as the tide would be unusually high under even favourable weather—in fact, give a forecast of the tide.

It is almost useless to ask the public or vestries to put two or three facts together and think out the matter for themselves; they require some authoritative announcement to prepare for danger. And this is the more necessary as an overflow of the Thames at above-average spring tides is, as Mr. Roberts says, now a matter of meteorological circumstances only, and on account of the increased range of the tide in the river.

I was not aware that Captain Saxby had predicted high tides so far back as 1869. If, as Mr. Roberts says, the Astronomer-Royal wrote re-assuring the public that there was nothing extraordinary in the November 3 tide, and as, on the contrary, that tide rose 3 feet 3 inches above Trinity high-water mark, this incident may possibly have had something to do with the establishing of Captain Saxby's reputation with the public as a predictor of tides, especially if he had previously predicted the great tide of March 1 of the same year, which rose to 3 feet 7 inches above the mark.

With respect to the actions of the planets, I did not refer to the ordinary tide-producing power, for on working that out some years ago for one of the planets I was somewhat surprised to find that the height was, I believe, a fraction of an inch. I referred rather to the action of that storm-producing power which apparently gives rise to the great atmospheric disturbances at certain times (and, indeed, more or less at all times) in the sun, and by sympathy, or even directly, in our atmosphere.

B. G. JENKINS

Diffusion Figures in Liquids

PROF. MARTINI describes his diffusion figures as being "both new and singular." In the *Phil. Mag.* for June and November, 1864, I have described and figured various examples of what I call "the submersion figures of liquids" in continuation of a series of papers commenced in 1861 on "The Cohesion Figures of Liquids," or those assumed by liquid drops when delivered to various surfaces. Some of these figures are identical with those given by Mr. Worthington in the *Proceedings* of the Royal Society for 1876, and recently in your pages. C. TOMLINSON

Highgate, N., December 3

Bees and Flowers

IN last Thursday's impression (p. 62) is a letter from Mr. H. O. Forbes, referring to bees confining their visits to plants of one kind during each excursion, and thus in a measure preventing hybridisation of plants, &c.

This may be the general habit of bees, but it is not invariable; some bees, more especially their females, are to be found at certain plants only, as *Andrena hattorfiana*, at the scabious *Colletes succincta*, at the heath, and many others in like manner.

I have collected bees for several years, and have often taken them with the pollen-grains varying from orange-red to almost white, and this mixture on the same leg. I have inclosed a slide of pollen-grains which I washed from the leg of an *Andrena nigro-ænea*, and mounted in balsam; this shows several very distinct kinds of pollen; this was mounted in 1875, and at the time I gathered such of the wild flowers as were then in bloom, and compared the pollen. I was able to identify several of them, but as I made no notes I cannot say which. I would advise such observers as intend investigating this very interesting subject, to capture the insects and examine the pollen which may be found on them; this will be difficult in the case of the Bombi and Apis, as they knead it into pellets, but with those which collect on the belly or whole leg it will be easy enough.

Norwich JOHN B. BRIDGMAN

Hearing in Insects

MY daughter bred this summer a number of the larvæ of *Sphinx ligustri* and *Metopsilus elpenor*, and I was much struck with the extreme sensitiveness to the sound of the voice—especially of the former. The child's treble I observed did not affect them so sharply; but at the first word I uttered they invariably started, and remained some time motionless, with head drawn back, after their manner. I was disposed to attribute it to the vibration set up in objects around by sounds toward the deeper end of the scale, as I have felt a form tremble under me at the deep bass notes of a strong singer; but it had all the appearance and effects of hearing. HENRY CECIL

Bregner, Bournemouth, December 1

A ZOOLOGICAL STATION FOR THE CHANNEL ISLANDS

SOME definite prospect at length presents itself of the establishment within British waters of an institution long recognised as a leading desideratum among our Biologists, Museum-Conservators, and Natural History Students, namely, a building with the necessary appurtenances suitably situated, and founded on a somewhat similar basis to that of Dr. Anton Dohrn's noted Zoological Station at Naples, or the Anderson School of Natural History at Penikese Island, Buzzard's Bay, U.S. This long-felt need will be met by the proposed "Channel Islands' Zoological Station and Museum, and Institute of Pisciculture" described at some length in the advertising columns of this journal, and the establishment of which, or a similar institution, has been the guiding star and main object of the writer's ambition during the several years' "apprenticeship" spent by him as Naturalist and Curator to the various leading public aquaria of England.

Successfully carried out, the more prominent features of this undertaking will comprise, as at Naples, in addition to an attractive public exhibition of the living inhabitants of the surrounding waters, laboratories fitted with tanks, tables, and all the necessary instruments and apparatus requisite for the satisfactory prosecution of marine biological research, supplemented by a library replete with the standard scientific works and serials mostly in demand by those occupied in such investigation. Under the same roof it is likewise intended to establish a natural history museum accessible to the public, and more essentially illustrative of the notably rich marine fauna and flora of the Channel Islands. In connection with the library and museum departments popular lectures upon natural history subjects will from time to time be given. Following the system productive of such gratifying results at the Penikese Island Station, it is further proposed for the full development of the scientific advantages of this institution to institute summer classes for the attendance of students, and to hold out sufficient inducements for the most eminent authorities on various biological subjects to deliver lectures and a course of instruction to these classes upon that branch of natural history with which their reputation is more especially associated.

An entirely novel feature to be incorporated with the Channel Islands' Zoological Station will be a department relegated to the conduct of experiments associated with the—in this country—little developed science of economic pisciculture, and in which department it is proposed to award a prominent place to the artificial rearing of lobsters. Experiments made in this direction by the writer some years since at the Manchester Aquarium have decisively shown that the artificial culture of these crustacea on an extended and systematic scale might be developed into a highly important and remunerative industry. In the experiments here referred to it was found that the little lobsters occupied from six to eight weeks in passing through those singular free swimming larval conditions, known respectively as the "Zoea" and "Megalops" stages, antecedent to their assumption of the adult and ambulatory form, and during which short interval they exuviated or cast their shells many times. These initial metamorphoses safely past, their further development to a marketable size, is a comparatively easy task. The scientific culture of the oyster and other edible species will likewise receive attention in association with this undertaking.

The appropriateness of Jersey as a site for this intended Museum of Pisciculture and Zoological Station is at once apparent, the variety and exuberance of the marine fauna of the Channel Islands being such as to assimilate it more closely to that of the Mediterranean than any other one within British waters. The occurrence on the Channel Islands' coast of the Sea Horse (*Hippocampus*), Urchin-fish (*Diodon*), Remora (*Echeneis*), Electric Ray (*Torpedo*), and Lancelet (*Amphioxus*), among the vertebrate group; and of the *Haliotis*, *Scyllarus*, *Comatula*, *Physalia*, *Velella*, *Lucernaria*, and many others among the invertebrate section, are a few from among many that might be named in demonstration of this fact. The sponge-tribe and the division of the tunicate might be likewise specially singled out as attaining upon the shores of these islands a development in both numbers and variety rarely if anywhere else excelled. Unprecedented facilities for the collection of all such marine productions are also afforded by the extraordinary low limit to which the water recedes during the monthly spring-tides. In no case less than thirty, and not unfrequently more than forty feet represents the vertical height of the rise and fall of the tide on these occasions, the waves on their retreat exposing to view and rendering accessible an extent of rocks and life-teeming pools that constitute a veritable elysium to the marine zoologist or botanist. The situation of Jersey, again, is such as to render it not only readily accessible to English naturalists and students, accompanied with just that amount of sea-passage requisite to satisfy the marine predilections of our countrymen, but it is also most conveniently reached from France, Belgium, Holland, and other Northern European countries, and which will thus invest the institution with international utility. Paris, indeed, already supplies a considerable number of the numerous summer visitors to the island, and from these no doubt might be enticed a strong contingent of students for the laboratories.

As will be found in the advertisement already referred to, a special appeal is addressed to the scientific section of the community rather than to the general public for the funds required for the successful establishment of this institution, and it is certainly most desirable that an enterprise calculated hereafter to confer so great advantages upon this more limited class should receive a fair quota of support through its ranks. The sum total required, in fact—5,000*l.*—for the founding of this zoological station, and all accessory departments, is so comparatively small as to place it not quite beyond the pale of hope that sufficient enthusiasm to effect the purpose may be yet forthcoming from among the more wealthy devotees to the shrine of science, and in emulation of the praiseworthy example set on the other side of the Atlantic by Mr. John Anderson, the munificent founder and endower of the Penikese Island Station. At all events, it is scarcely to be anticipated that so desirable an undertaking, replete with such promise of future advantage to the scientific world, will long lack the essential "sinews of war," considering that a contribution by each member of one only of our leading metropolitan scientific societies of less than one-half of his annual subscription to that society, would more than suffice to defray the whole expenditure contemplated. Through the kind liberality of a few, moreover, and the financial confidence of others, a small but substantial nucleus has been already formed, and it is confidently hoped that the full sum needed may yet be raised in time for naturalists and the public generally to participate in the advantages the Channel Islands' Zoological Station and Museum of Pisciculture will place at their disposal, so early as the summer of the year 1878.

In conclusion it is perhaps desirable to note that in drawing up the legal foundation of this Channel Islands' institution the strictest care has been taken to permanently exclude all possible chance of the society's premises being used for any of those attractions of an entirely irrelevant and unscientific nature more usually associated with exhibitions of the living inhabitants of the ocean, and the existence of which must ever constitute an insuperable barrier to that good service to science which these last-named establishments might otherwise contribute. It is only under such restrictions as are above set forth that patronage and support are solicited. In recognition of the purely scientific status of this enterprise, the members of the Executive Committee, or Directors of the Society, have also unanimously resolved to accord their services as such members gratuitously; and it is further proposed, so as to divest the undertaking of any merely speculative aspect, that all profits arising from the business of the Society, beyond what would yield to the shareholders a return of five per cent., shall be devoted to the further development of the institution, or otherwise towards the aid and promotion of scientific research.

St. Helier's, Jersey W. SAVILLE KENT

GERMAN UNIVERSITIES

THERE have been comparisons made recently both in this and in other journals between the Universities of Germany and those of this country, and as the university question is at present giving rise to much discussion, it may be useful to give some statistics with reference to the former. Such statistics are much more easily attainable for Germany than for England, as there are two German publications in which all the important information concerning the various universities of the empire is systematically arranged, viz., the *Deutsche Universitäts Kalendar* and the *Deutsche akademisches Jahrbuch*. To obtain similar information concerning the universities of the United Kingdom it would be necessary to obtain a copy of the calendar of each university. Our statistics are obtained from the *Jahrbuch*, which contains information not only relating to the universities, but also to the technical and high schools, learned societies, and libraries of the country. Some such publication is wanted here, and might be made to include not only our various universities and colleges, but also our principal public schools. The *Jahrbuch* includes, moreover, the Russo-German University of Dorpat, the Universities of Vienna, Graz, Innsbruck, Prague, Czernowitz, Basel, but these we shall not take into account.

Germany has in all twenty-one universities, each complete in all departments. The number of students matriculated and non-matriculated attending each, mostly in the 1876-77 semester was as follows:—

	Matriculated Students				Non-matriculated.	Total.
	Theology.	Law.	Medicine.	Philosophy.[1]		
Berlin	139	1003	281	1067	2107	4597
Bonn	163	200	118	312	36	829
Breslau	107	377	165	458	15	1122
Erlangen	136	37	102	147	—	422
Freiburg	41	64	128	60	36	329
Giessen [2]	—	—	—	—	10	331
Gottingen	71	324	122	474	—	991
Greifswald	32	89	235	142	9	507
Halle	190	150	103	439	16	898
Heidelberg	9	410	101	215	60	795
Jena	66	101	71	201	20	459
Kiel	47	14	73	78	11	223
Königsberg	44	186	127	264	10	631
Leipzig	328	1102	364	1182	113	3089
Marburg	49	65	104	164	4	386
Munich	75	357	440[3]	408[4]	—	1280
Munster	208			223	—	431
Rostock	24	35	31	54	—	144
Strassburg	49	211	178	236[5]	26	700
Tübingen	295	251	138	335[6]	6	1025
Würzburg	150	93	547	328	22	1040
	2223	5069	3428	6787	2501	20229

Thus, then, there are about 18,000 matriculated students attending the twenty-one universities of Germany, under a teaching staff of about 1,300 paid professors, besides about 450 privat-docenten. Of the students, about one-third belong to the philosophical faculty, the faculty in which the sciences are included. Unfortunately, in very few cases is the number of students attending the scientific as distinct from the literary classes given, and only in one or two universities has science as yet been erected into a separate faculty. If we may take the two universities, Strassburg and Tübingen, in which natural science forms a separate faculty as a criterion from which to judge of the number of students of science in the other universities, the proportion must be very large. In Strassburg, of the 236 students whom we have placed in the philosophical faculty, ninety-seven are students of science, and in Tübingen 100, or something like one-third of the whole philosophical faculty. Or again, if the number of science students is at all in proportion to the number of science teachers, the position held by science in German universities is in striking contrast to its position in our universities and colleges. Of the professors, among whom we do not count the privat-docenten, about one-half belong to the philosophical faculty, and of these again, nearly one-half are teachers of science, that is, in the philosophical faculty of the German universities there is one teacher on an average to every ten students, and in science the proportion is considerably greater. In these estimates we do not take account of the medical faculty, in which, in most of the universities, there are several chairs which might well be classed as belonging to science generally.

---

[1] In "Philosophy" are included the physical and natural sciences.

[2] The Giessen students are divided into Hessian and non-Hessian, not according to faculties.

[3] Including 100 students of pharmacy.

[4] Including 9 students of forestry.

[5] Including 97 mathematical and natural science students, these being a separate faculty at Strassburg. The figures are for 1875-6.

[6] Including 53 students in political economy and 141 in natural science these subjects forming separate faculties at Tübingen.

For example, the well-known anthropologist, Dr. Virchow, the conclusion of whose address at the German Association we give this week, is Professor of Pathology at Berlin, and has been able to bring the results of his special medical line of investigation to bear, in an important way, upon his anthropological researches. Both in Berlin and elsewhere, other names of eminent medical professors might be mentioned who have not only themselves made important contributions to science, but under whom students are encouraged to do so likewise.

Of the nature and extent of the scientific teaching in German universities some idea may be formed from the subjects represented by the teaching staff at Berlin, which may fairly be taken as a type of the whole. In Berlin then we find that there are (excluding the privat-docenten) five professors of mathematics, two of astronomy, seven of chemistry, five of physics, three of geology, four of botany, two of zoology, one of meteorology, two of geography, one of anthropology, and one of agriculture physiology and comparative anatomy being well represented in the medical faculty, and we might well have included among teachers of science those who devote themselves to the scientific investigation of languages. But a mere statement of the number of teachers gives no adequate idea of the means at the command of a German University for training its students in science. The number of teachers in each subject secures that its various departments will be thoroughly worked out, and gives a student a chance of following out any specialty he may take up; this is made still further possible by the number and variety of institutions, museums, laboratories, collections, &c., attached to each university, not to speak of its large and comprehensive library. In connection with Berlin alone there are twenty-three scientific "Anstalten," as they are called, for practical investigation in connection with the various faculties. Had we taken the numerous Realschule and the high and polytechnic schools into account, where an education can be obtained quite equal to that obtainable at most of our universities and colleges, it would have been seen that higher education in Germany leaves little to be desired.

And in reference to the subject of our leader this week, we would point to these Realschulen as embodying the German idea of what *practical* training should be. The carefully drawn-up time-tables of these schools are an instructive study, showing, as they do, that general mental culture is regarded as of the first importance in training a youth for the work of the world.

The *Jahrbuch* gives a statement of income and expenditure in connection with only one or two of the universities. Some interesting details, however, on the contributions of the State to the universities, as well as on other points, were given in a recent number of the *Academy* by Prof. Ray Lankester:—

"The sum expended by the North German States on the twenty universities belonging to them is annually more than 500,000*l.* The Imperial Government has expended upon the new University of Strassburg alone 70,000*l.* in one year. The University of Leipzig alone receives annually from the Saxon Government over 50,000*l.* There are eight universities in North Germany which are little, if at all, less costly, and there are eleven of smaller size which receive each from 8,000*l.* to 20,000*l.* annually.

"In North Germany there is one university to every two million inhabitants; in Austria there is one to every five millions; in Switzerland one for each million; in England one to every seven millions. In the twenty North German universities there are 1,250 professors.[1] In the British Islands we ought to have sixteen universities and 1,000 professorships in order to come up to the same level in this respect as North Germany. The stipend (apart from fees) of a professor in a German university ranges from 100*l.* to 600*l.* a year. As a rule, at the age of five and-thirty, a man in this career may (in Germany) count on an assured income of 400*l.* a year (with retiring pension). The expenditure on attendants, libraries, laboratories, and officials may be calculated as being (in a well-conducted university) more than equal in amount to the total of the professors' stipends. Taking the *average* German professorial stipend at only 200*l.* a year, we find that 250,000*l.* must be spent annually on this item alone in the North German States.

"In order to equip and carry on sixteen universities in this country which should bear comparison with the German universities, we require not less than an immediate expenditure of 1,000,000*l.* sterling in building and apparatus, and an annual expenditure of from 500,000*l.* to 800,000*l.*"

When we add to the Government subsidy the income of the universities from other sources, the sum is enormously increased. The half-million, moreover, does not include the occasional grants of the Government for special purposes. Some idea of the magnificence of these was shown in our recent "University Intelligence," where it was stated that in the budget submitted to the present Prussian House of Deputies are the following items:—Erection of the German Industrial Museum, 908,000 mk.; erection of a Polytechnic in Berlin, 8,393,370 mk.; erection of an Ethnological Museum in Berlin, 1,800,000 mk.; and for the Berlin University, erection of an Herbarium, 422,000 mk.; of a Clinic, 1,955,000 mk.; of a new building for a second Chemical Laboratory, as well as of a Technical and Pharmaceutical Institute, 967,000 mk.

OUR ASTRONOMICAL COLUMN

THE METEORITE OF JULY 20, 1860.—The occurrence of the splendid meteor of November 23, which has probably been observed with sufficient completeness to allow of the determination of its path, while it remained visible, recalls a similar object which passed over the northern parts of the United States and adjacent parts of Canada, on the evening of July 20, 1860, which was made the subject of investigation by the late Prof. J. H. Coffin, of Lafayette College, N.Y. Probably no one of these remarkable bodies has been more extensively observed, and we do not remember any case where the calculations have been more laboriously conducted, and with greater hope of reliable results.

---

[1] [illegible] we presume professors strictly so-called, exclusive of "privat docenten."

The "meteoric fire-ball," as Prof. Coffin calls it, was first seen moving in an easterly direction from a point nearly over the western shore of Lake Michigan, though it may have become luminous somewhat further to the west as the sky was clouded over that region. From thence it was watched until it disappeared out at sea in a south-easterly direction from the island of Nantucket. Its course was therefore about 1,300 miles, and it was seen for several hundred miles on either side of this track. Upwards of 230 descriptions of the meteor were collected, and upon the best of these Prof Coffin undertook the determination of the orbit, by an elaborate process detailed in his memoir, which formed No. 221 of the "Smithsonian Contributions to Knowledge," entitled "On the Orbit and Phenomena of a Meteoric Fire-ball, seen July 20, 1860." The various accounts of the meteor are printed in the memoir, and reveal some peculiar points of interest in its path. There were two "remarkable ruptures of the main body of the meteor," particularly near the meridian of 77° west of Greenwich, when it separated into two parts nearly equal in size which disappeared below the horizon, as one observer describes it, like a chain-shot

Considering that whatever might have been the orbit of the meteor before it became visible, its course while it was under observation, from being so near the earth, must have been controlled almost wholly by her attraction. Prof. Coffin mentions that the orbit he has investigated is not the path of the meteor in space, but the orbit relative to the earth, having the centre of our globe in one of its foci. Approximate elements having been obtained, azimuths and altitudes deduced from them were compared with those given by the various observations to ascertain what modifications of the elements were required in order to satisfy them. It was found that with certain corrections thus indicated the first orbit represented tolerably well most of the reliable observations to the west of 76° or 77°, near which the most easterly of the two points from which it was determined, was situated; but further to the east the discrepancies between calculation and observation were "so great that they could be reconciled only by introducing changes in the elements of the orbit, one on the meridian of 77° and another near the meridian of 74°, and as Prof. Coffin remarks, it is worthy of note that it was in the vicinity of these points that observers report the violent ruptures of the body of the meteor, which seems to afford a rational explanation of the changes of elements found to be required. It was apparent that while the meteor descended rapidly towards the earth till it reached the meridian of about 74°, it afterwards rose, and the change was too great to be accounted for on the supposition that the meteor at that point attained the perigee of its hyperbolic orbit. After the introduction of other considerations, it resulted that the path divided itself into three sections, "the first and third of indefinite length, over only a small portion of which the meteor was visible, and the second an intermediate one, 160 miles long, where it was most brilliant." The elements for the three sections, as finally adopted, are:—

	Sec. I.		Sec. II.		Sec. III.
	° ′		° ′		° ′
Long. of perigee	294 57	...	275 37	..	261 2
" descending node...	332 56	...	325 11	...	329 24
Inclination to ecliptic	66 12	...	67 10	...	66 26
Eccentricity	2·9984	...	2·9817	...	2·9921
Major semi-axis	2005·3	...	2005·3	...	2005·3
Perigeal distance	4007	...	3974	...	3995

The major semi-axis and the perigeal distances are expressed in miles. According to these elements, Prof. Coffin concludes that the meteor entered the sphere of the earth's attraction from the direction of the constellation Sextans, in about R.A. 148°, N.P.D. 87°, and left it toward a point in R.A. 355°, N.P.D. 121°.

The Planet Mars and B.A.C. 8129.—The near approach of Mars to the seventh-magnitude-star, B.A.C. 8129, appears to have been observed pretty generally. Taking the mean place of the star from the Washington Catalogue of 1860, its apparent position on the evening of November 12 is found to be R.A. 23h. 14m. 24·37s., N.P.D. 96° 34′ 22″·5. By Leverrier's tables the place of Mars at 6h. Greenwich time and the hourly motions were:—

R.A.	23h.	14m.	24s·91	+	3s·4734.
N.P.D... ...	96°	34′	25″·1	−	30″·494.

Taking account of parallax, the star at 6h. would be on an angle of 319°·4, distant from planet's centre, 17″·8, by calculation, as seen at Greenwich. Probably the actual approach was not quite so close.

The Binary-star Castor.—Dr. Doberck, of Col. Cooper's Observatory, Markree, whose investigations relating to the orbits of the revolving double-stars have been on several occasions referred to in this column, has corrected the elements of the fine binary α Geminorum, given by Thiele in 1859, by measures to 1877 inclusive. Thiele's period of revolution was 997 years, Dr. Doberck's calculation gives 1,001 years, and the comparison with observations, from those of Bradley and Pound in 1719 to the present year, exhibits no larger differences than are to be attributed to unavoidable errors, or in one or two cases, bias on the part of the observer. The new elements are as follow:—

Passage of the peri-astre	1749·75
Node	27 40 (meridian of 1850).
Node to peri-astre on orbit ...	207 13
Inclination	44 33
Eccentricity	0·3292
Semi-axis major...	7″·43
Revolution	1001·21 years.

This orbit gives, for 1878·0, position 234°·9, distance 5″·76.

Transits of the Shadow of Titan across the Disc of Saturn.—Mr. Marth has drawn attention to the following dates of transit of the great satellite's shadow, as the only opportunities for observation until the year 1891:—December 9, about 6¼h. Greenwich time, December 25, about 5¾h., and January 10, about 5h.

The "Nautical Almanac," 1881.—As usual the *Nautical Almanac* was published in November, the last volume being for the year 1881, which does not appear to be one distinguished by any particular astronomical phenomena. The two solar eclipses on May 27 and November 21, the first partial, the second annular, are both invisible in this country, and the line of annularity in the November eclipse runs at great south latitude. The total eclipse of the moon on June 11 will also be invisible here, while in the partial eclipse on December 3 (magnitude 0·97) the moon will rise at Greenwich about twenty minutes after first contact with the shadow. A transit of Mercury on November 7, will be wholly invisible in this country, the first external contact (geocentric) taking place at 10h. 16m. 13s., and the last at 15h. 37m. 41s. mean times at Greenwich. The list of visible occultations does not contain any planet, nor any star over the third magnitude. The list of standard stars is on the same scale as for the year 1880, and numbers close upon 200. The *Nautical Almanac* circulates to the extent of more than 20,000 copies, inclusive of the number appropriated for the use of the Royal Navy.

OLE RÖMER

When Newton's "Principia" raised the theory of astronomy to a height not previously dreamt of, practical astronomy was still where Tycho Brahe left it almost a century before. Such was the respect paid to nomers were in possession of a skill in handling their apparatus which has since been lost. It should also be taken into account that the telescopes of Hevel's day were generally of Dutch construction, and Kepler's tube, with wires in the field to mark the centre, was first brought into general use by Auzout and Picard about the end of the century. Of hardly less importance was the application of the pendulum to clocks, which from that time have been used as astronomical instruments. They had in Tycho's observatories been used merely to show what o'clock it was when observations were made, but never to determine differences of right ascension.

With sufficiently good clocks it was possible to determine the positions of the stars by observations in the meridian alone, and it was no doubt Picard who first became aware of the immense advantage of this. Consequently he solicited Government for a large mural quadrant, but Cassini was then called in from Italy, and no notice was taken of the request made by Picard, who, unfortunately for the practical astronomy of France, was not thought much of by the court of Louis XIV., his important, but modestly-conducted researches being eclipsed by Cassini's brilliant discoveries. Had Picard got the direction of the Royal Observatory in Paris he would have been able to make further improvements in the construction of instruments; but with no sufficient means at hand, he ascribed the partial failure of his attempts to the small size of his instruments. A mural quadrant like Tycho Brahe's, but furnished with a telescope, was first fixed at the observatory when Picard died.[1] Flamsteed and Sharp adopted the methods just as Picard left them and with all their drawbacks. They used the quadrant both for right ascensions and declinations. Their observations may perhaps be said to be twice as accurate as Hevel's naked-eye observations.

This was the state of practical astronomy when Römer raised it to a height which was not surpassed before Bessel. Ole Römer was born in Aarhus on September 25, 1644. Thence he came, 1662, to Copenhagen, where he studied mathematics and astronomy under Erasmus Bartholin,

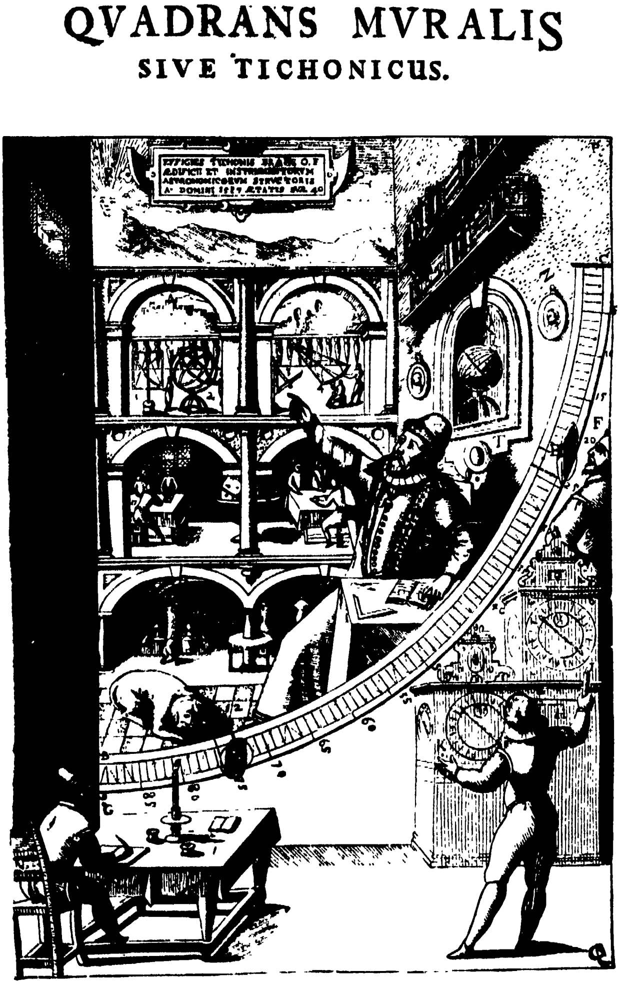

FIG. 1.

observations of the eclipses of the first satellite of Jupiter. His results, which were not very exact, were, however, contested by Cassini and most other authorities for a long time after. Indeed, the theory of the motion of the satellites was at that time so little elaborated, that similar conclusions might be questioned all the more as they had been deduced from observations of the first satellite alone. Römer shortly afterwards discovered the epicycloid, and published a paper on the proper form of toothed wheels, and descriptions of a Jovilabium and Saturnilabium; he afterwards invented different kinds of

---

[1] This interesting instrument is represented in Fig. 1. It was cast wholly in brass and fixed with strong iron screws as exactly as possible in the meridian in the south-western room of the ground-floor of Uraniburg. Its radius was about six feet, and it could by means of transversals be read off to ten seconds of arc. It had in a hole in the south-western wall in the centre a gilt cylinder and two pinnules movable along the edge, which were so constructed that the slit could be opened or closed more or less according to the faintness or brightness of the objects to be observed. Tycho Brahe, who, in contradistinction to Ole Römer, was not only anxious about the quality but also about the appearance of his instruments, had ornamented the large empty space of the quadrant with the splendid picture shown in the plate. He is here depicted in his usual attire. At his feet is lying one of his favourite hunting-dogs, more as a symbol of ingenuity than as a symbol of nobility. Behind him are small portraits of King Frederick and Queen Sofie. This was painted by John of Antwerp and is more like him than any other image, but the space contained also an architectonic picture by Steenvinkel, somewhat reduced as it at a distance. In the upper story are represented some of his most celebrated instruments, in the middle story the library inside with the large celestial globe and his pupils occupied with their studies, and in the cellar the chemical laboratory. On the plate is seen a young man observing through one of the pinnules, another is watching the clocks, while a third is noting down their remarks at a table. Tycho Brahe's image seems as if admonishing and instructing them in their work.

[2] On this occasion fire-signals were for the first time made use of for the determination of longitude. A fire was lit on the top of the astronomical tower in Copenhagen. There Picard eclipsed it at regular intervals, and the moment the light disappeared was noted by the observers on Hveen.

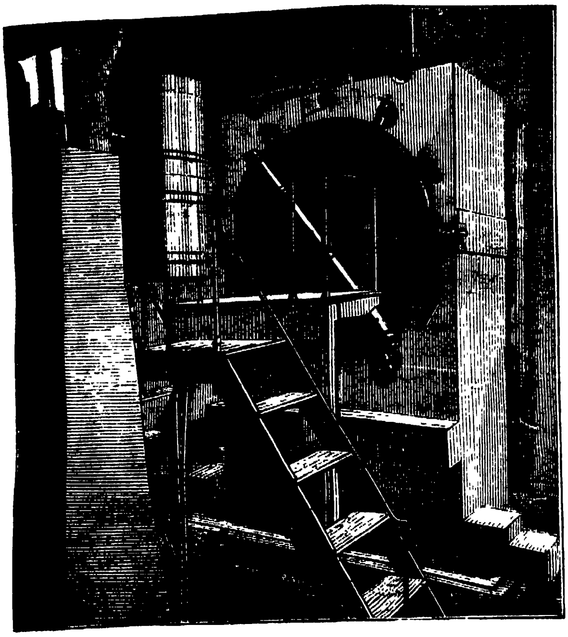

FIG. 2.—Mural Circle, U.S. Naval Observatory.

which gave him occasion to write several interesting papers. He made many observations in Paris. Already in 1671 he had taken part in the observations of the altitude of Mars, which was simultaneously observed by Richer in Cayenne, for the determination of the parallax of the sun. His fame increased so much that he was made tutor to the Dauphin, and in 1681 Christian V. called him to Denmark as Astronomer-Royal. His great technical knowledge made him useful to that country in many ways, and we see him in succession as Professor of Mathematics, Mayor of Copenhagen, Master of the Mint, Prefect of the Police, Privy-Councillor, and one of the Judges of the Supreme Court, in all of which capacities he left behind a lasting fame. He was one of the first who recommended Protestants to adopt the calendar as reformed by Gregory XIII. He had also to make a journey in 1687 to acquaint himself with the latest progress in naval architecture and pyrotechnics. We cannot fail to respect his perseverance when we hear that, notwithstanding so many different occupations, he left behind about as many observations as Tycho Brahe himself. But these were mostly all lost by the great fire which devastated the town in 1728.

Römer found in Copenhagen the old observatory of Longomontanus on "the round tower" almost devoid of instruments, and it was first in 1690 that two were placed there. One of these was not unlike a modern equatorial, and intended for extra-meridian observations; but it was generally clamped in the meridian, and used as a transit circle. The other was a vertical circle for taking corresponding altitudes, a method much used by Picard. The position of these instruments on the top of the tower (over 100 feet high), where the observations had to be made under the open air, rendered their use, however, so inconvenient to the observer, that Römer about the same time arranged an observatory in one of the windows of his dwelling house. Here was placed the transit instrument which Römer invented, but it was greatly inferior to the instrument he afterwards constructed. The telescope was not fixed in the middle of the horizontal axis as in modern instruments, but near one end. The axis, which rested on iron supports in the wall, was a long and thin iron bar, furnished with a counterpoise acting in the middle, to prevent flexure. The tube itself was cone-shaped for the same reason. In the focus were drawn a horizontal and a number of vertical wires. The interval between the three he generally used was thirty-four seconds in the equator, and the time was noted to half seconds. The field was illuminated by means of a polished ring placed outside of the object-glass. The circle was not movable with the telescope but fixed to the wall, and the telescope carried with it a microscope fixed upon an arm for reading the declinations. The arc was divided to ten minutes and in the microscope were eleven wires, each one minute distant from its neighbour. The minutes were read thus and could be subdivided by estimates to about four seconds. The instrument being placed in a window Römer could only observe the stars of between twenty-eight south and forty degrees north declination, and the arc was therefore not a whole circle but merely about seventy degrees. The error of collimation was corrected by reversion. The azimuth was ascertained by comparing the observed error of the clock with that determined by corresponding altitudes. It was at this observatory that Römer tried from observations of the right ascensions of two bright stars on opposite sides of the sky, to determine the sum of their parallaxes.

But these arrangements did not long satisfy Römer, and in 1704 he built, at his own cost, the "Observatorium Tusculaneum," seventeen feet long and broad, near the village Vridlösemagle, between Copenhagen and Roeskilde. The principal instrument of this observatory was a meridian circle, and the stars were observed through a very narrow opening in the ceiling and the walls running

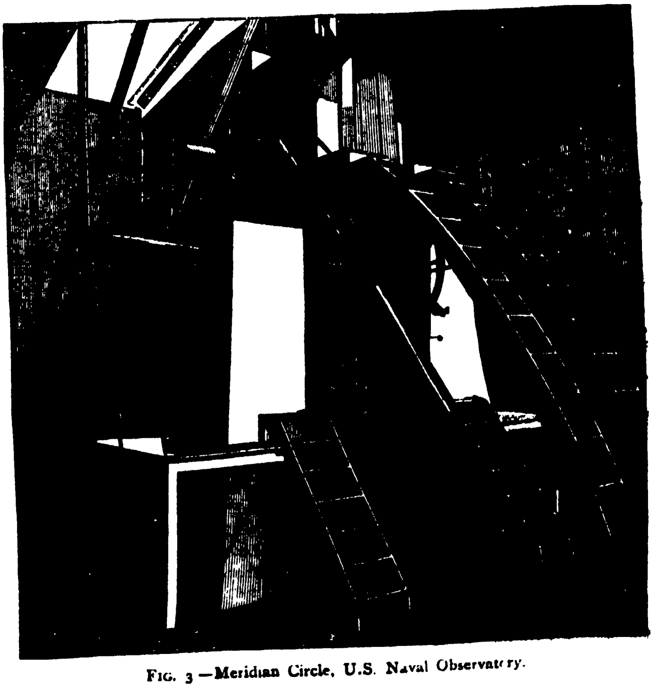

FIG. 3.—Meridian Circle, U.S. Naval Observatory.

from north to south, which was closed with shutters when not in use. The axis was made of conical iron plates lighter and more inflexible than in the old transit. The pivots were conical and fitted into brass holes on the sides of the pillars, into which the axis was tightly pressed with screws. The axis could be shifted a little both in altitude and azimuth. Römer had afterwards occasion to regret that the instrument was supported on wooden pillars and not on stone. The tube was not fixed immediately to the axis but to the circle. It was five feet long, and allowed stars of the second magnitude to be observed during the day. It had three horizontal wires in the focus and seven vertical; the intervals between these were twenty-four seconds in the equator, and the time was noted to a fraction of a second. There were three good clocks in the observatory. The circle which was fastened to one end of the axis was about five feet in diameter. It is not unlikely that Römer afterwards considered a smaller size preferable. He disapproved altogether of the use of the quadrant and sextant, and said that a circle of four feet was superior to a quadrant of ten. This circle had been divided to ten minutes with Römer's own hands, and in the microscopes three seconds were easily discerned. It was read by two microscopes fixed side by side to one of the supports of the axis. Before the observations were made the circle was ascertained, by means of a plumb-line, to be vertical. The errors of collimation and azimuth were determined in the same way as with the old instrument, and Römer had fixed two meridian-marks, which were besides used to discover whether the microscopes had changed their position. Römer was the first who determined the azimuth from culminations of circumpolar stars above and below the pole.

Besides this instrument Römer had also a transit instrument placed in the first vertical, but that was not used much because it had been so badly made by the workmen that it disturbed the meridian circle with which it had one of the supports in common Römer intended to observe declinations of fixed stars with it and compare them with those observed in the meridian, and thereby determine the refractions. He would also have observed the sun with it.

After Römer's death, on September 19, 1710, his observatory was neglected and the instruments were spoiled, when at last they were sent to Copenhagen. Römer was to have published a description of the observatory and his methods, but was prevented by the illness which terminated his active career, and the descriptions were afterwards given from memory by his little gifted pupil and successor, Horrebow, who did not fully understand all the precepts of his great master. All his observations and instruments were ultimately destroyed by the conflagration of the observatory in 1728, except three days' observations, which Römer had intended to use for his description of the instruments. Thus it came to pass that this great genius passed away without any adequate influence upon the progress of the science. These three days' observations have been carefully reduced by Dr. Galle; their accuracy is shown to be almost equal to that attained at the present day.

In England the methods adopted by Flamsteed were followed until Bradley permanently introduced Römer's transit at Greenwich. He continued, however, to use the quadrant for declinations, and in most other observatories of this country the right ascensions and declinations continued to be observed with different instruments. We may also trace to this circumstance the immovable heavy mural instruments so common in this country.[1] The French astronomers adhered to Picard's methods until lately, and used quadrants even for the right ascensions; the transit in the first vertical was not used before it was rediscovered by Bessel. On the whole we may say tha no observatory fully expressed Römer's ideas before Bessel's and Struve's practical talents had altogether changed the face of the science.

W. DOBERCK

---

[1] On the accompanying plates are represented one of the formerly mor common mural circles (Fig. 2), and also a meridian circle (Fig. 3); both instruments of the U.S. Naval Observatory, Washington.

NOTES

PROF. KIRCHHOF has been created a Knight of the Order of Maximilian for Science and Art, by King Louis of Bavaria.

M. BRUNET, the late French Minister of Public Instruction, nominated M. Gramme, the inventor of the well-known machine for generating electric light, a Chevalier of the Order of the Legion of Honour.

NEARLY 200*l.* have already been promised for the Darwin Memorial Fund at Cambridge.

A MONUMENT was inaugurated on November 23 at Rouen in honour of M. Pouchet, the celebrated naturalist, who organised the Rouen Museum in 1828, and died director in 1872. M. Pouchet was a correspondent of the French Institute. He was a supporter of the theory of spontaneous generation.

THE Rhine Provincial Museum in Bonn has succeeded in purchasing the famous collection of prehistoric remains from the Neander Valley, hitherto in the possession of the late Prof. Fuhlrott, of Elberfeld, although a high price had been offered from England.

PREPARATIONS are being made at the Champ de Mars, Paris, for executing Foucault's pendulum experiments on an enlarged scale. His apparatus was suspended in 1851 under the dome of the Pantheon. It was in operation for a long while and removed only when the building was transformed into a church after the *coup d'état* in 1852. The weight of the pendulum will be 300 kilogrammes, and it will oscillate at the end of an iron wire from 65 to 70 metres long. Thus a special construction will be required for its suspension. The pendulum will be suspended above a grooved pipe which will move freely on an axis in its centre. The pendulum in oscillating will displace this pipe, which will remain, like the pendulum itself, fixed in space, in reference to the constellations. Underneath the pendulum will be arranged a large terrestrial globe, from 25 to 30 metres in diameter. This globe, resting on the ground, will necessarily follow with the spectators the movement of the earth. The pipe, on the contrary, supported by a pivot at the extremity of the axis, will carry large indexes, which will appear to be displaced with it. The globe, which will represent the earth, having a considerable volume, the movement of these indexes will be visible; it will render tangible in some degree to the least attentive, the rotation of the planet on its axis.

IN the *Times* of Monday is a pleasant leader on the Royal Society *à propos* of the anniversary last Friday. The article contains nothing striking, the drift of it being that the Royal Society has done much to foster science, but that science never was altogether, and is now not at all, dependent on the Royal Society for its progress—which is probably true. The article concludes with a strongly-expressed desire to see literature, "the old learning," recognised by the Royal Society, that, in fact, it should be turned into a sort of academy, after the pattern of that of Paris. But practically the French Academy is a collection of societies, one of which, like the Royal Society, devotes itself wholly to science.

AN article in Tuesday's *Times* describes some experiments which are being made at the Fulham gas-works in the lighting of lamps by electricity. The patent is that of Mr. St. George Lane Fox, the distinctive feature being an electro-magnetic apparatus attached to each lamp, and connected with a central station, at which an electric current is generated. If the experiments prove successful and the apparatus is adopted, a great saving is likely to be effected. All practical difficulties seem, however, to have been solved in America Electricity has been tried for the purpose of lighting and extinguishing 220 street lamps in Providence, R. I., scattered over a district nine miles long. One man attends to the whole business and does it in fifteen seconds. The method has now been on trial for some months, and a saving of ten dollars per lamp per year is reported.

As might have been expected, Mr. Stanley has been received with unbounded enthusiasm at the Cape, and his followers petted and loaded with presents to such an extent that they must feel amply rewarded for all their labours. Mr. Stanley in his lecture at Cape Town, reported in the *Times* and *Telegraph*, went over all his journey again, and defended himself stoutly against the criticisms which have been made on his conduct. He is expected in England about Christmas. The United States House of Representatives are to pass a vote of thanks to Mr. Stanley, and the King of Italy is to present him with a gold medal. Would it not be just to recognise, in some public manner, the great service rendered to geography by the organisers of the expedition, the proprietors of the *Telegraph* and *Herald*?

COL. W. H. REYNOLDS has concluded a contract with the English Government by which the Post Office Department has adopted the Bell telephone as a part of its telegraphic system. In a recent telephonic experiment in connection with the cable 21¾ miles long, between Dover and Calais, there was not the slightest failure during a period of two hours. Though three other wires were busy at the same time, every word was heard through the telephone, and individual voices were distinguished. This important experiment was conducted by Mr. J. Bourdeaux, of the Submarine Telegraph Company. Some very successful experiments were made with the telephone on Saturday night between Aberdeen and Inverness, a distance of 108 miles. Songs and choruses were distinctly transmitted, and conversation was carried on at times with marvellous distinctness, notwithstanding the weather was unfavourable. The experiments were made with Prof. Bell's instruments. The Berlin correspondent of the *Daily News* states that a Berlin house is making a number of telephones for experimental use in the Russian army. The result is awaited with great curiosity in military circles. The *Cologne Gazette* denies that any telephone is in existence between Varzin and Bismarck's office at Berlin. Our contemporary says that the distance, 363 kilometres, is too large for using a telephone with any advantage.

ON Dec. 1 the council of the Paris Observatory held its second meeting for deliberating upon the improvements to be suggested to the Government. The existing regulations had been printed and distributed among members, who discussed them article by article, in order to better understand their bearing. M. Faye, the present Minister of Public Instruction and one of the councillors, did not resign his office. He merely intimated to his colleagues that he should not take part in the discussions so long as he should be obliged to remain a minister for the welfare of the commonwealth. Consequently it may be considered as certain that the Assembly will come to no conclusion so long as the political crisis does not permit the learned astronomer to resume his usual labours. M. Faye, whose voice will have great weight, is a strong supporter of the existing connection between astronomy and meteorology.

THE Society of Apothecaries have decided to offer two prizes for competition by young women under twenty years of age, in the science of botany. The prizes will consist of a gold and a silver medal and books, to be awarded to the first and second candidates respectively in order of merit. The Rev. M. J. Berkeley (the examiner for the prizes given by the Society to medical students) will conduct the examinations. The date of the examination and the conditions of competition will be published shortly.

A PRIZE of 1,000 Italian lire has been offered by the Committee of the Italian Alpine Club for the best description of any Italian mountain group.

THE Horseshoe at Niagara, the *New York Tribune* states, is now a right-angle rather than a curve. The rocks in the centre have been eaten away from year to year, and now the side walls are crumbling. On November 17 a large section of rock toward the Canada shore fell with a tremendous crash, and during the night a still larger area went down. The falls now wear a new face, and visitors will undoubtedly be charged twenty-five cents extra next season.

THE Russian Government has issued an ukase according to which Novaya Zemlya is to be colonised. The Norwegian journal *Tromsoeposten* now reports that on August 28 last six Russian sailing vessels arrived at Tromsoe, carrying the necessary building materials such as timber, bricks, and lime for the construction of six houses upon Novaya Zemlya. These houses were to be constructed during the course of the present autumn and are to be inhabited by six Samojede families, who will form the first colonial residents upon the island. The Russian Government hopes by the colonisation of Novaya Zemlya to be able to establish successfully a permanent commercial communication with the mouths of the Yenisei and Obi Rivers, while at the same time the new colony may form a convenient place of exile for political criminals.

THE deepest artesian well in the world is being bored at Pesth, and has reached already a depth of 951 metres. The well at Paris, which measures 547 metres has hitherto been the first. The work is undertaken by the brothers Zsigmondy, partially at the expense of the city, which has granted 40,000*l.* for the purpose, with the intention of obtaining an unlimited supply of warm water for the municipal establishments and public baths. A temperature of 161° F. is shown by the water at present issuing from the well, and the work will be prosecuted until water of 178° is obtained. About 175,000 gallons of warm water stream out daily, rising to a height of 35 feet. This amount will not only supply all the wants of the city, but convert the surrounding region into a tropical garden. Since last June the boring has penetrated through 200 feet of dolomite. The preceding strata have supplied a number of interesting facts to the geologist, which have been recorded from time to time in the Hungarian Academy of Sciences. Among some of the ingenious engineering devices invented during the course of the boring are especially noteworthy the arrangements for driving in nails at the enormous depth mentioned above, for pulling them out (with magnets), for cutting off and pulling up broken tubes, and above all, a valuable mechanical apparatus by means of which the water rising from the well is used as a motive power, driving the drills at a rate of speed double that previously imparted from the mouth of the well.

THE preliminary works for boring the British Channel Tunnel are being prosecuted with very great activity at Sangate. A shaft has been sunk to a depth of 100 metres, and the experimental gallery has been commenced. It is to be continued for a kilometre under the sea. If no obstacle is met with the work will be continued without any further delay. Two powerful pumps have been established for elevating the water which, of course, filters in in large quantity.

IN the French estimates for 1878 a supplementary credit of 5,000*l.* is asked for the learned societies in connection with the exhibition of 1878.

AN international exhibition is to be held at Milan in 1879.

AN excellent measure was decided on by M. Brunet, the late French Minister of Public Instruction. Special maps on the scale of $\frac{1}{100000}$ are to be designed of the country around each college, so that pupils when out walking, may be enabled to practice topography. These maps will extend to a radius of thirty kilometres from the college, and will be placed in the hands of masters.

THE Geographical Society of Paris will hold its anniversary meeting on December 19; a banquet will take place at the Grand Hotel on the 22nd.

THE administration of the Eastern Railway of France has intimated to the Geographical Society of Paris that orders will be given for inscribing on the wall of each station the altitude above the sea, the distance from Paris, the name of the chief town of the district, the name of the department, &c., &c. Thus railway travellers will learn the geography of France *nolens volens*.

IN last week's NATURE Mr. G. J. Hinde gave some details concerning the earthquake of November 4 in Canada. The *New York Tribune* gives some interesting details concerning the same earthquake in the States as well as subsequent earthquake phenomena. The shocks were felt in the east, in the west, and in the south. Commenting upon them the *Chicago Evening Journal* makes an interesting statement about the recent active condition of a little-known volcano in Nebraska. The latest earthquake shocks, it states, which especially affected Western Iowa, and were still sharper in North-eastern Nebraska and South-western Dacota, bring to mind the fact that the "Ionia Volcano," known to a few scientific investigators of the west as existing in the high bluffs near the little village of Ionia, in North-eastern Nebraska, is directly in the centre of the area traversed by the earthquake vibrations. Being in a retired spot, miles away from any line of travel, on the west bank of the Missouri River, in a bluffy region, the little volcano has attracted the attention of only a few of those who make such subjects a study, and hence is not mentioned, as we believe, in any of the works on geography or geology. The occurrence of the earthquake, with its key or centre at the Ionia volcano, makes worthy of remark the fact that for a few months past this little American Vesuvius has been unusually active. Its vapours have arisen almost constantly, and, for the first time since white men have viewed its action, these vapours have been easily distinguishable for a dozen or more miles away. The first of these disturbances of the earth's surface was perceived on November 4 by the inhabitants of Northern New Hampshire, Vermont, Western Massachusetts, Northern and Central New York, and Canada. The course of the shocks was from west to east. They were especially violent in the Adirondack Mountains region. On November 15 an earthquake shock was felt in the States of Kansas, Nebraska, and Iowa, and in Dakota Territory. The shock was a very severe one, and its effects were perceptible in most of the cities of the States mentioned. In Sioux City, Iowa, there were two earthquake waves, the second being the most powerful and immediately following the first. There was a continuous vibration lasting forty-five seconds. In Kansas the shock was noticed at Topeka and Atchison. At Topeka, in the Santa Fé depot, the employés felt the building rocking gently from north to south. On November 16, the day following the earthquake in the west, a violent earthquake shock was felt at Knoxville, Tenn. The shock was apparently only perceived at this place in the south, as there are no reports from any other southern city of such an occurrence.

NOTHING is as yet known about the Marquis Antinori and his expedition. The news of his death, which did not emanate, we believe, from the Italian Geographical Society, may therefore be considered as premature. Matteucci, who takes a lively interest in the fate of the Antinori expedition, will probably be able to gather more precise and definite information at Khartoum.

PROF. STOPPANI, the eminent Italian geologist, has been called to occupy the chair of geology at the Instituto Superiore of Florence. He delivered his opening discourse on Saturday, November 17, and will give exclusively public lectures during the whole following scholastic year.

THE "Science Primers" by Hooker, Balfour Stewart, and Geikie, have been translated into Italian by Profs. Pedicino, Cantoni, and Stoppani, and published in nicely-bound small volumes by the editor, U. Hoepli, of Milan.

THE enormous whale captured in the Gulf of Taranto in February last, has now been studied by Prof. Capellini, who found it to be a new species, to which he gives the name of *Balæna tarentina*.

WE are informed that Dr. Forsyth Major, of Florence, intends to publish a periodical for the "Zoology and Palæontology of Vertebrata," which will contain original articles in four languages. We cannot but wish the best success to Mr. Major's interprise, which is the first of the kind in Italy or anywhere else, we believe.

A NEW and perfectly mounted meteorological observatory, under the direction of Prof. Nardi, was inaugurated on Sunday, November 25, in the Seminary of Fiesole, near Florence. The funds for the same were subscribed by the Bishop of Fiesole and the Italian Alpine Club Another observatory will shortly be opened under the care of the latter society, at Castel Piano, on Mount Amiato, near Siena. The number of meteorological stations in Italy thus amounts to about eighty, the greater part of which have been founded on the initiative, and by the support, of the Club Alpino, who deserve every praise for their continual and strenuous efforts to further and foster the study of meteorology in Italy.

A MOST elaborate monograph has been published by a distinguished Italian geologist, Prof. Baretti, on the geology of the large Alpine group known under the name of Gran Paradiso in the Graiian Alps.

IN the *Annali di Storia naturale del Museo Civico di Genova*, the illustrious traveller and botanist, Prof. O. Beccari, describes the wonderful gallery or bower-constructions of the *Amblyornis inornata*, observed by himself in the Arfak Mountains. The huts and gardens, as built and laid out by this bird, which is called "the gardener," seem to surpass any production of intelligence and taste for the beautiful hitherto described and observed in birds of the Paradise family.

ON the very rich collections made in, and sent over from, New Guinea by those intrepid and persevering champions of science, Messrs. O. Beccari and D'Albertis, Prof. Mantegazza has completed a series of anthropological and ethnographical studies, the first part of which are now being published in the *Archivio per l'Antropologia e la Etnologia*. It may be mentioned that the museum, founded by Prof. Mantegazza in Florence contains the largest known collection of Papuan skulls, the number of which exceeds two hundred.

THE additions to the Zoological Society's Gardens during the past week include a Vervet Monkey (*Cercopithecus lalandii*) from South Africa, presented by Mr. F. H. Taylor; a Green Monkey (*Cercopithecus callitrichus*) from West Africa, presented by Mr. J. R. Phillpotts; a Spotted Ichneumon (*Herpestes auropunctatus*) from Persia, presented by Mrs. Fleuss; a Common Ocelot (*Felis pardalis*), a Scarlet Ibis (*Ibis rubra*), a Fulvus Tree Duck (*Dendrocygna fulva*) from South America, presented by Mr. George Ransom; a long-eared Owl (*Asso otus*), European, presented by Mr. W. H. Millington; three Weeper Capuchins (*Cebus capucinus*), a Squirrel Monkey (*Saimaris sciurea*) from South America, two Cheer Pheasants (*Phasianus reevesii*) from North India, purchased; a Black-footed Fox (*Canis jubata*) and an Azara's Fox (*Canis azaræ*) from South America, deposited.

THE LIBERTY OF SCIENCE IN THE MODERN STATE[1]

III.

IF what I have said before is true—that half-knowledge is more or less the characteristic of all naturalists, that in many, perhaps in most, of the lateral branches of their own science, even the naturalists themselves are only half-knowers; if later on I said that the true naturalist was distinguished by his being perfectly aware of the limit between his knowledge and his ignorance, then you understand, gentlemen, that also with regard to the public at large we must confine our claims to demanding that merely what every single investigator in his own direction, in his sphere, can designate as reliable truth which is common to all—that only this shall be admitted into the general plan of education.

In thus marking the confines of our knowledge we must remember before all things that what is generally termed natural science is, like all other knowledge in this world, composed of three totally different parts. Generally a difference is only made between *objective* and *subjective* knowledge, but there is a certain intermediate part—I mean *belief*—which also exists in science, with this difference only, that here it is applied to other things than in the case of religious belief. It is somewhat unfortunate, in my opinion, that the expression belief has been so completely monopolised by the church, that one can hardly apply it to any secular object without being misunderstood. In reality there is a certain domain of belief even in science, upon which the single worker no longer undertakes to prove what is transmitted to him as true, but where he instructs himself merely by means of tradition, just what we have in the church. I would like to remark on the contrary—and my conception has not been contradicted by the church—that it is not belief alone which is taught in the church, but that even ecclesiastical dogmas have their objective and their subjective sides. No church can avoid developing in the three directions I have pointed out: in the middle the path of belief, which is certainly very broad, but on the one side of which there is a certain quantity of objective historical truth, and on the other a variable series of subjective and often very fantastic ideas. In this the ecclesiastical and the scientific doctrines are alike. The cause of this is that the human mind is a simple one, and that it carries the method which it follows in one domain finally into all the others as well. But we must be aware at all times how far each of the directions mentioned extends in the different domains. Thus, for instance, in the ecclesiastical domain—it is easier to show it in this one—we have the real dogma, the so-called positive belief; about this I need not speak. But each creed has its peculiar historical side. It says: this has happened, this has occurred, these events have taken place. This historical truth is not simply handed down, but in the garb of an objective truth it appears with certain proofs. This is the case with the Christian religion just as much as with the Mohammedan, with Judaism just as much as with Buddhism. On the other side we find the left wing as it were, where subjectivity reigns; there the single individual dreams, there visions come and hallucinations. One religion promotes them by special drugs, another by abstinence, &c. Thus subjective individual currents are developed, which occasionally assume the shape of perfectly independent phenomena existing by the side of and apart from the previous ecclesiastical domain, which at other times are rejected as heresies, but which often enough lead into the large current of the recognised church. All this we find again in natural science. There too we have the current of the dogma, there too we have the currents of the objective and subjective doctrines. Consequently our task is a compound one. First of all we always try to reduce the dogmatic current. The principal aim of science has for centuries been to strengthen more and more the right, the conservative side. This side, which collects the *ascertained facts* with the *full consciousness of proof*, this side, which adheres to *experiment as the highest means of proof*, this side, which is in possession of the real scientific treasury, has always grown larger and broader, and this principally at the expense of the dogmatic stream. Really, if we only consider the number of natural sciences which since the end of last century have grown and now flourish, we must admit that an almost incredible revolution has taken place.

There is no science in which this is so eminently evident as in medicine, because it is the only science, which has a continuous history of nearly 3,000 years. We are, so to speak, the patriarchs of science, inasmuch as we have the dogmatic current at its longest. This current was so strong, that in the early part of the middle ages even the catholic church embraced it, and the heathen Galen appeared like a father of the church in the ideas of men; indeed, if we read the poems of that period, he often presents himself exactly in the position of a church dignitary. The medical dogma went on until the time of the Reformation. As contemporaries of Luther, Vesal and Paracelsus came and made the first grand attempts at reduction, they drove piles into the dogmatic stream, constructed dykes by its sides, and left only a narrow fair-way to it. Beginning from the sixteenth century it has grown narrower and narrower every century, so that finally only a very small channel has remained for the therapeutists. Thus vanishes the lordliness of the world.

Only thirty years ago the Hippocratic method was spoken of as something so sublime and important that nothing more sacred could be imagined. Nowadays we must own that this method is annihilated nearly down to its root. At least, a good deal of imagination is necessary if we say that any physician of the present day acts as Hippocrates did. Indeed, if we compare the medicine of to-day with the medicine of the year 1800—accidentally the year 1800 marks a great turning-point in medicine—then we find that our science has undergone a complete reformation during the last seventy years. At that time the great Paris school was formed, immediately under the influence of the French Revolution, and we must admire the genius of our neighbours that enabled them to find all at once the fundamental basis of an entire new discipline. If now we see medicine continue its development in the greater breadth of objective knowledge, we will never forget that the French were the precursors, as in the middle ages the Germans were.

By our own example I only wished to show you shortly what changes both the methods and the storehouse of knowledge undergo. I am convinced that in medicine, at the end of the present century, only a sort of clay-pipe system will have remained, through which the last weak waters of the dogmatic stream may move—a sort of drainage. For the rest the objective current will probably have entirely consumed the dogmatic one.

Perhaps the subjective one will remain as well. Perhaps even then many an individual will dream his beautiful dreams. The field of objective facts in medicine, great as it has become, has yet left such a number of lateral fields, that for anybody who *wants* to speculate, plenty of opportunities offer daily. And these opportunities are honestly made use of. A multitude of books would remain unwritten if only objective things were to be communicated. But the subjective wants are still so great, that I believe I am justified in maintaining that of our present medical literature about one half might safely remain unpublished, without doing any damage worth mentioning to the objective side.

Now when we *teach*, in my opinion, we ought not to look upon this subjective side as an essential object in the doctrine. I believe I now belong to the oldest professors of medicine; I have taught my science now for over thirty years, and I may say that during these thirty years I have honestly striven by myself to free my mind more and more from all subjective tendency, and to get more and more into the objective current. Nevertheless I openly confess that I find it impossible to give up subjectivity altogether. Every year I see again and again that even in points, where I had believed myself to be entirely objective, I still retained a large number of subjective ideas. I do not go so far as to make the inhuman demand that everybody is to express himself entirely without any subjective vein, but I do say that we must set ourselves the task to transmit to the students the real knowledge of facts in the first place, and if we go further, we must tell them each time: "but this is not proved, but this is *my* opinion, *my* idea, *my* theory, *my* speculation."

This, however, we can only do with those who are already educated and developed. We cannot carry the same method into the elementary schools, we cannot say to each peasant boy, "This is a fact, this we know, and that we only suppose." On the contrary, that which is known, and that which is only supposed, as a rule get so thoroughly mixed up that that which is supposed becomes the main thing, and that which is really known appears only of secondary importance. Therefore we who support science, we who live in science, are all the more called upon to abstain from carrying into the heads of men, and most of all into the heads of teachers, that which we only suppose. Certainly, we cannot give facts only as raw material, that is impossible. They must be arranged in a certain systematic order. But we must not extend this arrangement beyond what is absolutely necessary.

---

[1] Address delivered at the Munich meeting of the German Association, by Prof. Rudolf Virchow, of Berlin. Continued from p. 94.

This is a reproach which I cannot help making against Prof. Nägeli as well. Prof. Nägeli has discussed, certainly in the most measured way and—you will notice this if you read his address—in a thoroughly philosophical manner, the difficult questions which he has chosen as subjects for his address. Nevertheless he has taken a step which I consider extremely dangerous. He has indeed done in another direction what is in one way done by *generatio æquivoca*. He asks that the mental domain shall be extended not only from animals to plants, but that finally we shall actually pass from the organic world into the inorganic with our conceptions of the nature of mental phenomena. This method of thinking, which is represented by great philosophers, is natural in itself. If anyone wants by any means to connect mental phenomena with those of the rest of the universe, then he will necessarily come to transfer the mental processes, as they occur in man and the animals of highest organisation, to the lower and lowest animals; afterwards a soul is even ascribed to plants; further on the cell thinks and feels, and finally he finds a passage down to chemical atoms, which hate or love one another, seek one another, or flee from one another. All this is very fine and excellent, and may after all be quite true. It *may* be. But then, do we really want is there some positive scientific necessity, to extend the domain of mental phenomena beyond the circle of those bodies, in which and by which we see them really happening? I have no objection if carbon atoms have a mind as well, or that they obtain a mind in their union with the plastidule association, but *I do not know in what I am to recognise this*. It is simply playing with words. If I declare attraction and repulsion to be mental occurrences, to be mental phenomena, then I simply throw the mind (*die Psyche*) out of the window; then the mind ceases to be mind. The phenomena of the human mind may eventually be explained in a chemical way, but for the present, I think, it is not our task to mix up these domains. On the contrary, it is our duty to keep them strictly where we understand them to be. And as I have always laid stress upon this, that we should not in the first line try to find the *transition* from the inorganic into the organic, but that we should first of all determine the *contrast* between the inorganic and the organic, and carry on our investigations among those contrasts in the same way, I now maintain that the only way to progress—and I hold the firmest conviction that we shall not advance at all otherwise—is to limit the domain of mental phenomena where we really perceive mental phenomena, and not to *suppose* mental phenomena, where perhaps they *may* be, but where we do not notice any visible, audible, sensible, in one word, *perceptible* phenomena, which we might call mental ones. There is no doubt that for us the whole sum of mental phenomena is attached to certain animals, not to the totality of all organic beings, not even to all animals generally, and I maintain this without hesitation. We have no reason yet to say that the lowest animals possess mental characteristics; we find them only with the higher animals, and with perfect certainty only with the highest.

Now I will admit with pleasure that certain gradations, certain gradual transitions, certain points can be found, where from mental phenomena one gets to phenomena of simply material or physical nature. I certainly do not declare that it will never be possible to bring psychical phenomena into immediate connection with physical ones. All I say is, that *at present* we are not justified in setting down this *possible* connection as a scientific *doctrine*, and I must distinctly oppose the attempts to enlarge our doctrines prematurely in this manner, and to bring again and again into the foreground as a positive statement what we so often proved a useless problem. We must distinguish strictly between what we want to teach and what we want to investigate. What we investigate are problems. We need not keep them to ourselves; we may communicate them to the whole world and say, There is the problem, this is what we are trying to find; like Columbus, who, when he started to discover India, made no absolute secret of it, but who eventually did not find India, but America. And the same happens to us not rarely. We start to prove certain problems which we suppose to be perfectly correct, and in the end we find something quite different, which we never expected. The investigation of such problems, in which the whole nation may be interested, must be open to everybody. That is the *liberty of research*. But the problem is not at once to be the object of instruction. When we teach we must confine ourselves to those smaller domains which are already so large, and which we have actually mastered.

Gentlemen, I am convinced that only with a resignation of this kind, which we impose on ourselves, which we exercise towards the rest of the world, shall we be enabled to conduct the fight against our enemies with a victorious result. All attempts to transform our problems into doctrines, to introduce our theories as the basis of a plan of education, particularly the attempt simply to depose the church, and to replace its dogma by a religion of descent without further trouble, these attempts, I say, must fail, and their failure would at the same time bring the greatest dangers upon the position of science generally.

Therefore let us be moderate, let us exercise resignation, so that we give even the most treasured problems which we put forth, always as problems only, and that we say it a hundred and again a hundred times: "Do not take this for confirmed truth, be prepared that this may perhaps be changed; only for the moment we are of opinion *that it may be true*."

By way of illustration I will add another example. At this moment there are probably few naturalists who are not of opinion that man is allied to the rest of the animal world, and that a connection will possibly be found, if indeed not with apes, then perhaps in some other direction, as is now the opinion of Prof. Vogt.

I acknowledge openly that this is a desideratum of science. I am quite prepared for it, and I would not for a moment wonder nor be alarmed if the proof were found that the ancestors of man were vertebrate animals. You know that just at present I work by preference in the field of anthropology, but yet I must declare that every step of positive progress which we have made in the domain of prehistoric anthropology, has really moved us further away from the proof of this connection. At this moment anthropology studies the question of fossil man. From man in the present "period of creation" we have descended to the quaternary period, to that period when, as Cuvier maintained with the greatest confidence, man never existed at all. Nowadays quaternary man is a generally accepted fact. Quaternary man is no longer a problem, but a real doctrine. But tertiary man is a problem—of course a problem which is already in a stage of material discussion. There are objects already about which discussions are going on as to whether they may be admitted as proofs for the existence of man during the tertiary period. We do not merely speculate on the subject, but we discuss certain objects, whether they may be recognised as witnesses for the activity of man during the tertiary period. The question raised is answered differently according to whether these objective material elements of proof are considered sufficient or not. Even men who, like Abbé Bourgeois, are decided ecclesiastics, are convinced that man has lived during the tertiary period; for them tertiary man is already a doctrine. For us, who are of a more critical nature, tertiary man is still a problem, but, as we must acknowledge, a problem worthy of discussion. Let us therefore for the present remain at quaternary man, whom we really find. If we study this quaternary, fossil man, who ought after all to stand nearer to our ancestors in the series of descent, or rather of ascent, we find a man just the same as we are ourselves.

Only ten years ago, when a skull was found, perhaps in peat or in lake dwellings, or in some old cave, it was believed that wonderful marks of a wild and quite undeveloped state were seen in it. Indeed we were then scenting monkey air. But this has died out more and more. The old troglodytes, lake inhabitants, and peat people turn out to be quite a respectable society. They have heads of such a size that many a person living would feel happy to possess one like them. Our French neighbours have certainly warned us not to conclude too much from these big heads; it may be possible that they were not filled only with nerve-substance, but that the old brains had more intermediary tissues than is the case now-a-days, and that their nerve-substance in spite of the size of the brain, remained at a low state of development. However this is only a friendly conversation which to some extent is held as a support of weak minds. On the whole we must really acknowledge that all fossil type of a lower human development is absolutely wanting. Indeed if we take the total of all fossil men that have been found hitherto and compare them with what the present offers, then we can maintain with certainty that amongst the present generation there is a much larger number of relatively low-type individuals than amongst the fossils hitherto known. That only the highest geniuses of the quaternary period enjoyed the good fortune of being preserved for us I do not dare to suppose. As a rule we draw conclusions from the condition of a single fossil object with respect to the majority of others which have not been found. But I will not do this. I will not maintain that the whole race was as good as the few skulls which were found. But I must say that one fossil monkey-skull or man-ape skull which really belonged to a human proprietor has never been found. Every addition which we have obtained in the material inventory of objects for discussion has moved us further away from the problem to be solved. Now of course we cannot avoid the consideration that perhaps it was on some quite special spot of the earth that tertiary man lived. This is quite possible, since during the last few years the remarkable discovery has been made in North America that the fossil ancestors of our horses occur in countries from which the horse had entirely disappeared for a long time. When America was discovered there were no horses there at all; in the very place where the ancestors of our horses had lived no living horse had remained. Thus it may also be that tertiary man has existed in Greenland or Lemuria, and will again be brought to light from under the ground somewhere or other. But as a fact we must positively acknowledge that there is always a sharp limit between man and the ape. *We cannot teach, we cannot designate it as a revelation of science, that man descends from the ape or from any other animal.* We can but designate this as a problem, may it seem ever so probable and may it lie ever so near.

We ought to be sufficiently warned by the experiences of the past, at a time when we are not justified in drawing conclusions, not unnecessarily to burden ourselves with the obligation, or yield to the temptation of drawing them all the same. Look you, gentlemen, it is in this that the difficulty lies for every naturalist who speaks to the world at large. Whoever speaks or writes for the public, ought, in my opinion, doubly to examine just now, how much of that which he knows and says is objective truth. He ought to try as much as possible to have all inductive extensions which he makes, all progressing conclusions by the laws of analogy, however probable they may seem, printed in small type underneath the general text, and to put into the latter only that which really is objective truth. In that case we might perhaps succeed in gaining an always increasing circle of followers, in obtaining an always increasing number of fellow-workers, and in causing the educated public to continue to take part in that fertile manner in which it has already taken part in many domains. Otherwise, gentlemen, I fear that we overrate our power. Certainly old Bacon said with perfect justice, *scientia est potentia*, knowledge is power. But he has also defined knowledge, and the knowledge which he meant was not speculative knowledge, not the knowledge of problems, but it was the objective knowledge of facts. I think that we should abuse our power, we should endanger our power, if in our teaching we do not fall back upon this perfectly justified, perfectly safe, and impregnable domain. From this domain we may as investigators make our excursions in the direction of problems, and I am convinced that every attempt of this kind will then find the necessary safety and support.

AMERICAN SCIENCE

THE principal paper in the *American Journal of Science and Arts* for November, is Prof. Marsh's able address at the recent meeting of the American Association, on the Introduction and Succession of Vertebrate Life in America, which we have given at length. —Discussing the question, Is the existence of growth rings in the early exogenous plants proof of alternating seasons? Dr. Warring concludes from observations, that some exogens form rings at intervals much less than a year; others require intervals of several years, and some form no rings. The presence or absence of rings in exogens occurs in all climates. Large and well-defined rings are found where there is absolutely no appreciable variation of temperature or moisture throughout the year. An exogen naturally forming rings will continue to form them, although the climate become uniform throughout the year. Thus the existence of these markings in ancient flora gives no information as to the existence at that time of seasons, and so far as they are concerned we are left free to adopt any conclusion as to inclination of the earth's axis, which may appear most reasonable. —Some years ago Prof. Newcomb showed that the improvements introduced into the theory of the moon's mean motion by Hanssen's lunar tables did not extend to the inequalities of long period in that motion. While Hanssen, by an empirical term had secured a very good agreement with observations from 1750 to 1860, this agreement was found to have been obtained by sacrificing the agreement before 1750, and the moon had then begun to deviate from the tables at such a rate that they could not continue satisfactorily to represent the observations. Prof. Newcomb has since attempted a complete discussion of all recorded observations of any astronomical value before the year 1750, and his suspicion has been entirely confirmed. The results of this examination are communicated. Comparing a theory of the moon's mean motion founded on gravity alone, with the observations, he is led to suppose that the deviations may be due to the action of some of the bodies of the solar system. He corrects Hanssen's term by an empirical addition.—Prof. Dana contributes to the number a note on the Helderberg formation of Bernardston, Massachusetts, and Vernon, Vermont, and Mr. Mallet describes "Serpylite," a new niobate, from Amherst County, Virginia.

The *New York Tribune* states that the Johns Hopkins Scientific Association has recently been organised in Baltimore. Prof. Sylvester is president, Prof. Remsen, vice-president, Dr. Story, secretary. A great feature in the programme is that the essays presented are to be short and concise, and to contain the particulars of original research exclusively. There is also to be a discussion of new scientific publications, both foreign and domestic, at the meetings, of which the first has been held, with a score of members present.

Under date November 20, the *Tribune* has the following telegram from Washington:—Messrs. S. H. Scudder of Cambridge, and F. C. Bowditch, of Boston, have just returned from a two months' tour in Colorado, Wyoming, and Utah, where, under the direction of Dr. Hayden, they have been exploring for fossil insects and collecting specimens especially in the high regions. They report having secured many specimens of fossil insects at different points along the railways from Pueblo to Cheyenne, and from Cheyenne to Salt Lake, as well as at Lakin, Kansas, and Garland, and Georgetown, Col., and in various parts of the South Park and surrounding region. Their time was so limited that they were unable to visit White River and explore the beds of fossil insects) known to exist there. Ten days were spent at Green River, and in that vicinity, in exploring the tertiary strata for fossil insects, but with very unsatisfactory results. Near Florisante the tertiary basin was found to be exceedingly rich in insects and plants. Mr. Scudder spent several days in the careful survey of this basin, and estimates that the extent of the insect-bearing shales there is at least fifty times as great as that of those in Southern Bavaria. Six or seven thousand specimens of insects, and 2,000 or 3,000 of plants have already been received from Florisante, and as many more are expected before the close of the year. Arrangements were also made with persons who have found a new and rich deposit of fossils in the tertiary strata in Wyoming to forward all the specimens obtained there. Mr. Scudder believes that the tertiary strata of the Rocky Mountain region are richer in the remains of fossil insects than any others in the world, and that within the next few months the amount of material at hand for the study of the subject will be greater than was ever before possessed by any single naturalist. Prof. Joseph Leidy, the comparative anatomist and microscopist, has also recently returned from his second visit to the west, under the direction of Dr. Hayden. His field of operations during the past season was the country about Fort Bridger, Unitah Mountains and the Salt Lake Basin. The specimens he has collected comprise the lowest and simplest forms of animal life, the most minute requiring high microscopic power to distinguish their structure.

THE METEOR

WE have received some further communications concerning this remarkable phenomenon, and some interesting details concerning a similar body will be found in our "Astronomical Column." Mr. A. O. Walker writes from Chester:—

In reading the notice of the meteor of November 23 in NATURE, vol. xvii. p. 94, I am surprised to see no mention of any report from it. As I only heard it without seeing it I send you the notice of it from my diary, written immediately after the occurrence:—

About 8.30 P.M. heard a loud report like that of a cannon (say 32 lbs.), fired about 200 yards off, which shook the house, and the servants saw a bright flash. The sky overhead was quite clear and only cloudy on the horizon south and east. Thought it was the explosion of an aerolite."

Next day I made inquiries and added the following:—

"Parry and Field said the flash was blue, and five minutes elapsed between the flash and bang. Parry's girl was outside, and came in crying; said she had seen 'a very funny kind of lightning.' Parry remarked it shook his door."

The two men named above are in my employ, and live about 300 yards from my house. Some friends of ours living about two miles from us also saw the flash and heard the report, but the latter not so loud as we did. They described it as sounding as if a bird had flown against the window."

I give the above extracts *verbatim*, as first impressions, uninfluenced by what one hears or reads subsequently, are much the most valuable.

Dr. S. Drew, of Chapeltown, Sheffield, writes as follows:—

I send you the following calculations as to the meteor of November 23. They may interest some of your readers. The estimates are only intended as approximate, as the observations at different points of view were too vague for much accuracy, and indeed, in two instances, obviously quite unreliable.

The visible course of the meteor appears to have been from a point about 150 miles above the town of Worksop to the Irish Channel, north-west of Liverpool, probably nearly half-way between Liverpool and the Isle of Man—a direction from east by south to west by north, the horizontal distance traversed being rather over 100 miles and the perpendicular 150 miles. The size of the fire-ball before breaking up was about 150 yards in diameter. By this is meant the size of the luminous sphere, not that of the actual bolide, which would be much less.

The rate of motion was near twenty miles per second in horizontal, and thirty miles in perpendicular; as this in horizontal is little more than would be caused in appearance by the orbital and diurnal motion of the earth, it is evident that the proper motion of the meteor was nearly perpendicular to the earth's surface; and, if belonging to the solar system, it must have moved in a very eccentric orbit, stretching far beyond that of the earth. The meteor broke at an elevation of about fifty miles, and then appeared much larger. The fragments must have dropped into the sea.

Was it seen from Ireland or the Isle of Man?

S. A. K. writing to the *Manchester Courier* from Blackpool states that about 8.30 P.M. on the 23rd he beheld a ball of a pale blue colour shoot across the sky from east to west, followed by a train of rainbow lines, brilliant beyond description. "It was over in a moment; but as I and several others tood discussing the phenomenon we had just witnessed, two muffled booms as of far-distant cannon were distinctly heard in the west, after an interval of two or three minutes." Capt. Tupman writes from the Royal Observatory, Greenwich, to the *Times*: "There is reason to suppose that the great meteor which appeared at 8.20 P.M. on Friday last (November 23) fell into the sea near the mouth of the river Dee. From its splendour it was probably seen by many persons near the shores of North Wales, Cheshire, and Lancashire, whose observations would be of the greatest value; and I venture to solicit the publicity of your columns in order that such observations may be forwarded here. On Tuesday night (Nov. 27), at 10.26, G.M.T., I observed another pass slowly from a point about 6" over Castor to 5° left of Sirius. It remained in sight fifteen or sixteen seconds, determined by counting. Towards the end it became faint, of a dull red colour, and moved with extreme slowness. I have no doubt it must have appeared very large to observers near Dover and in Normandy, and it is to be hoped its path has been recorded elsewhere."

A meteor was observed at Strassburg on November 23, the very day when the meteor was observed in England, but the time was a little after six o'clock (local time), and the direction from north to south. A violent detonation was heard, but without any resemblance to that of thunder. The light was as vivid as ordinary lightning at Strassburg. A witness states that he saw the meteor [illegible] at a small distance from him (three or four metres) in a [illegible] belonging to the Chevaudier de Valdrome on the new road leading from Lorquin to the French frontier. All the trees were illuminated as if by daylight. It is not reported by the *Strassburg Gazette* whether any stone was found on the spot.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

OXFORD.—The Brackenbury Scholarship in physical science has been awarded to Mr. Cunningham, Balliol College.

LONDON.—The Council of University College have awarded the Sharpey Physiological Scholarship to Mr. Patrick Geddes and the Joseph Hume Scholarship in Political Economy of 20*l.* per annum for three years to Mr. J. G. Schurman.

EDINBURGH.—A public meeting, under the presidency of the Right Hon. the Lord Provost, was held on the 29th ult. at Edinburgh to advocate the claims of the Edinburgh University Buildings Extension Scheme. The cost of the new medical school, &c., will be about 187,000*l.*, and of that sum 82,000*l.* has been subscribed by the public and 80,000*l.* has been promised by Government on condition that the remaining 25,500*l.* be subscribed before the end of next year. It was announced that about 10,000*l.* of this has been promised, leaving upwards of 14,000*l.* still to be raised. In support of the appeal it was mentioned that in some class-rooms there is not sitting room for the students. The number of students is increasing every year, there being at present enrolled 212 more than at the same time last year, so that before the summer session is over there will probably be close on 2,500 students matriculated.

The first meeting of the fourth session of the Chemical Society of the University was held in the University on November 28, the president, Prof. A. Crum Brown, in the chair. The president gave an introductory lecture on the "Life and Works of Dr. Joseph Black." The following office-bearers were elected for the ensuing season:—President—Prof. A. Crum Brown; Vice-Presidents—J. Gibson, Ph.D., F.R.S.E., W. Inglis Clark, B.Sc.; Secretary—J. Adams; Treasurer—C. Maxwell, R.N. The society numbers fifty-two members, and ten new members were proposed.

MANCHESTER.—A Chemical Society has been commenced at the Owens College. The society is intended to include all students of science at the College—Dalton Scholars, Associates, and a few others connected now, or in the past, with the Science Classes of Owens College. The society was opened on Wednesday evening by an address from Prof. Thorpe, F.R.S. on "Robert Boyle and the Sceptical Chemist." The Syllabus of the society for the session is as follows:—"Are the Elements Elementary?" by Mr. Pattison Muir; "Graham," by Mr. P. P. Bedson, B.Sc.; "Berzelius," by Mr. J. K. Crow, B.Sc.; "Alkali Manufacture," by Mr. Bevan: "Crystallisation," by Mr. Baker; "Liebig," by Mr. C. F. Cross; "Valensy," by Mr. O'Shea; "Chemical Industry of Japan," by Mr. Siguira; and a paper, subject not settled, by Prof. Gamgee. It is hoped and believed that the society will tend to increase the interest in scientific pursuits already manifested by members of the College.

FRANCE.—A number of important measures have been taken by the French Minister of Public Instruction for fostering the zeal of students and professors in the several French faculties. By a decree issued on November 5 a number of scholarships have been created in each academy at the expense of the public exchequer. In future years scholars are to be appointed after having passed special examinations similar to those for exhibitions in the English universities. Exceptions are created in favour of students who have been particularly successful in taking their preliminary degrees and have published approved papers in the Academical *Transactions*, or have rendered special services in tuition. For the present year the different scholarships are to be granted by a special commission. Three of these commissions have been established—one for letters, another for science, and the third for medicine. These scholarships are to be continued only for a limited time, varying from two to four years, but are to be stopped at once if the scholar does not give satisfaction to the professors or lecturers. A part of these scholarships is to be granted to candidates for the mastership of arts (Licencié-ès-Lettres and ès-Sciences), and another part to the masters in several faculties wishing to take the highest honours in their respective faculties. By another decree, published on the same day, M. Brunet has created a number of lectureships styled "conferences." A number of the lecturers are to act as public tutors, helping public professors in their duties. Other lectureships are to be granted to professors teaching supplementary sciences which, up to the present time, have not come within the limits of the official programme. The salary of all of them is 120*l.*, and they are to be appointed yearly from among doctors or members of the academies. In some peculiar cases Masters of Arts are eligible to these lectureships. The new organisation is expected to work during the present classical year.

SOCIETIES AND ACADEMIES

LONDON

Geological Society, November 7.—Prof. P. Martin Duncan, F.R.S., president, in the chair.—Stephenson Clarke, William Hunter, and the Rev. W. Roberts, were elected Fellows of the Society. The following communications were read: A letter dated September 14 was read, from Lord Derby, stating that his lordship had received a despatch from her Majesty's Minister at Tehran, reporting that a mining engineer had arrived there from Berlin, who, at the request of the Persian government, had been selected by Messrs. Siemens to ascertain what foundation there was for the reported existence of a rich vein of gold in the vicinity of Zengan; that he had visited the locality and reported that auriferous quartz does exist, but that he had not yet succeeded in finding any vein or deposit of the metal.—Notes on fossil plants discovered in Grinnell Land by Capt. H. W. Feilden, Naturalist to the English North Polar Expedition, by Prof. Oswald Heer, F.M.G.S. Near Discovery Harbour, where H.M.S. *Discovery* wintered in 1875-6, in about 81° 45′ N. lat., and 64° 45′ W. long., a bed of lignite, from twenty-five to thirty feet thick, was found, resting unconformably upon the azoic schists of which Grinnell Land chiefly consists. The lignite was overlain by black shales and sandstones, the former containing many remains of plants; and above these there were, here and there, beds of fine mud and glacial drift, containing shells of marine mollusca of species now living in the adjacent sea. This glacial marine deposit occurs up to levels of 1,000 feet, indicating a depression and subsequent elevation of the region to at least this extent. Remains of twenty-five species of plants were collected by Capt. Feilden, and eighteen of these are known from miocene deposits of the Arctic zone. The deposit is therefore no doubt miocene. It has seventeen species in common with Spitzbergen (78° 79′ N. lat.), and eight species in common with Greenland (70° 71′ N. lat.). With the miocene flora of Europe it has six species in common; with that of America (Alaska and Canada) four; with that of Asia (Sachalin) four also. The species found include two species of *Equisetum*, ten Coniferæ, *Phragmites œningensis*, *Carex noursoakensis*, and eight dicotyledons, namely, *Populus arctica*, *Betula prisca*, and *Brongniarti*, *Corylus macquarrii* and *insignis*, *Ulmus borealis*, *Viburnum nordenskioldi*, and *Nymphæa arctica*. Of the Conifers, *Torellia rigida*, previously known only by a few fragments from Spitzbergen, is very abundant, and its remains show it to have been allied to the Jurassic genera *Phœnicopsis* and *Bæiera*, the former in its turn related to the carboniferous *Cordaites*, and among recent conifers, to *Podocarpus*. Other conifers are, *Thuites ehrenswärdi* (?), *Taxodium distichum miocenum* (with male flowers), *Pinus feildeniana* (a new species allied to *P. strobus*), *Pinus polaris*, *P. abies* (twigs covered with leaves), a species of *Tsuga Pinus dicksoniana*, Heer.), and a white spruce of the group of *Pinus grandis* and *cariocarpa*. *Pinus abies*, which occurs here and in Spitzbergen, did not exist in Europe in miocene times, but had its original home in the extreme north, and thence extended southwards; it is met with in the Norfolk forest-bed, and in the interglacial lignites of Switzerland. Its present northern limit is 69½° N., and it spreads over 25° of latitude. *Taxodium distichum*, on the contrary, spread in miocene times from Central Italy to 82° N. latitude, whilst at present it is confined to a small area. *Betula brongniarti*, Ett., is the only European species from Grinnell Land not previously known from the arctic zone. The thick lignite bed of Grinnell Land indicates a large peat-moss, probably containing a lake in which the water-lilies grew; on its muddy shores stood the large reeds and sedges, the birches, poplars, *Taxodia*, and *Torelliæ*. The drier spots and neighbouring chains of hills were probably occupied by the pines and firs, associated with elms and hazel bushes. A single elytron of a beetle (*Carabites feildenianus*) is at present the sole evidence of the existence of animals in this forest region. The nature of the flora revealed by Capt. Feilden's discoveries seems to confirm and extend earlier results. It approaches much more closely to that of Spitzbergen than to that of Greenland, as might be expected from the relative positions of the localities; and the difference is the same in kind as that already indicated by Prof. Heer between Spitzbergen and Greenland, and would indicate the same kind of climatic difference. Nevertheless, the presence of *Taxodium distichum* excludes arctic conditions, and that of the water-lily indicates the existence of fresh-water, which must have remained open a great part of the year. Representatives of plants now living exclusively in the arctic zone are wanting in the Grinnell Land deposits; but, on the other hand, most of the genera still extend into that zone, although they range in Grinnell Land from 12° to 15° further north than at present.—On our present knowledge of the invertebrate fauna of the lower carboniferous or calciferous sandstone series of the Edinburgh neighbourhood, especially of that division known as the Wardie Shales, and on the first appearance of certain species in the beds, by Mr. R. Etheridge, jun., F.G.S.

Zoological Society, November 20.—Prof. Flower, F.R.S., vice-president, in the chair.—Mr. Howard Saunders exhibited a specimen of the rare Aleutian Tern (*Sterna aleutica*) from Alaska, and made remarks upon its intermediate position between typical *Sterna* and the group of the Sooty Terns (*Onychoprion*).—A communication was read from the Marquis of Tweeddale, F.R.S., containing an account of a collection of birds made by Mr. A. H. Everett in the Island of Zebu, Philippines. Six new species were found in this collection, and were named *Oriolus assimilis*, *Phyllornis flavipennis*, *Zosterops everetti*, *Prionochilus quadricolor*, *Turnix nigrescens*, and *Megapodius pusillus*.—Three communications were read from Dr. O. Finsch, C.M.Z.S. The first contained a report on a collection of birds made at Eua, Friendly Islands, by Mr. F. Hübner, which had increased our knowledge of the avifauna of Eua from four to twenty-four species. The second contained a description of a collection of birds made on the Island of Ponapé, Eastern Carolinas, by Mr. J. Kubary. The total number of species known at present from Ponapé was stated to be twenty-nine, of which seven were peculiar to the island. The third contained a list of the birds obtained at Ninafou Island in the Pacific, by Mr. F. Hübner. This collection raised the number of the known birds of this island from one to twenty.—Prof. Garrod, F.R.S., read notes on the *Taenia* of the rhinoceros of the Sunderbunds *Plagiotaenia gigantëa*), on the anatomy of the Chinese water-deer (*Hydropotes inermis*), on the possible cause of death in a young seal, and on the occurrence of a gall-bladder in certain species of parrots.—Mr. Howard Saunders, F.Z.S., read a paper on the *Laridæ* collected during the voyage of H.M.S. *Challenger*, which comprised nine species of *Sternæ*, five of *Larinæ*, and three of *Stercorarinæ*, altogether seventeen species represented by forty-given specimens; several of these were very rare in museums, although none of them were absolutely new to science.—A communication was read from Dr. A. B. Meyer, containing some additional proofs of the fact that the Red *Eclecti* are the females of the green species of that genus.—A paper was read by Mr. G. French Angas, C.M.Z.S., containing notes on *Helix sepulcharalis* of Ferrusac, and its allies, with descriptions of two new species.

Physical Society, November 17.—Dr. Stone, vice-president, in the chair.—The president, Prof. G. C. Foster, described and exhibited a very simple form of absolute electrometer, which acts on the same principle as Sir W. Thomson's trapdoor form of apparatus, but can be constructed at a very moderate cost. To one arm of a balance is suspended by silk fibres a zinc disc, which hangs horizontally in the plane of a sheet of the same metal forming a guard-plate; and at a distance of about one inch below is a flat sheet of zinc, also horizontal. An electrical connection is formed between the guard-plate and suspended disc by a bridge of very fine wire. The method of using the apparatus to determine the potential required for a spark to pass from a Holtz machine through varying thicknesses of air was explained. When the balance has been accurately counterpoised, an excess weight, say one gramme, is introduced into the scale pan, and the guard-plate and the lower attracting-plate, as well as the two knobs of a spark-measurer, are connected with the conductors of the machine. If this be now set in action, and the knobs of the spark-measurer be gradually separated, a point will be reached at which the attraction upon the suspended disc just overcomes the excess weight in the balance pan. The length of spark for which this occurs can now be read off. The difference of potential causing the spark is given by the formula $\frac{e}{a}\sqrt{8F}$, where a is the radius of the attracted disc, e its distance from the attracting-plate, and F the force of attraction in dynes. In the apparatus exhibited, a had the value 5·195 cm., and e the value 2·4 cm., whence, if w be the excess weight in grammes—so that $F = 981\,w$—the difference of potential becomes $39\sqrt{w}$. The proper action of the apparatus depends essentially upon the attracted disc being accurately in the same plane with the guard-plate. To facilitate this adjustment, each of the silk fibres by which the disc is suspended is attached to a screw, by which it can be separately raised or lowered; and by means of another screw the small brass plate holding the suspending screws can be raised or lowered as a whole. A few numerical results were given to illustrate the action of the apparatus. These were taken from a set of experiments in which the difference of potential needed to produce sparks in air between two equal brass spheres of 2·61 cm. radius was measured. The following are the results for a few of the shortest and longest sparks measured:—

Length of Spark.	Difference of Potential.	Mean Electrical Force.
cm.		
0·1325	17·4	131
0·1825	20·4	117

VIENNA

Imperial Academy of Sciences, October 11.—Preliminary note on the position of the optical axes of elasticity in gypsum for various colours, by M. Lang. The angle of the optic axes shows a maximum for the Fraunhofer line D. The dispersion of the axes of elasticity in the plane of symmetry is abnormal. These observations agree on the one hand with Poggendorff's exact description of the axial forms of gypsum, and on the other side with Descloigeaux's observation that at the higher temperatures, where the plane of axis is at right-angles to the place of symmetry, no horizontal dispersion is observable.—Annual periods of the insect fauna of Austro-Hungary, by M. Fritsch.—On the relation between the second principal proposition of the mechanical theory of heat and the calculation of probability respecting the propositions on heat-equilibrium, by M. Boltzmann.—The cylindroid and its specialties, by M. Kozak.—Simple calculation of elliptic arches, by G. Seewald.—On eruptive sands, and on the Flysch and the *Argille scagliose*, by M. Fuchs.—On equal figures in curves, cones, and surfaces of the second order and of certain of higher orders, by M. Puchta.—Calculation of cylindrical vessels with complicated relations, by M. Streicher.—On development of the resinous passages in some coniferæ, by M. Weiss.—Continued studies on the mode of ending of nerves of smell, by M. Exnor.

PARIS

Academy of Sciences, November 26.—M. Peligot in the chair:—The following papers were read:—Geographical positions of the principal points of the coast of Tunis and Tripoli, by M. Mouchez. This relates to observations during the hydrographic voyage of the *Castor* in 1876, of some fifty points equally distributed along about 300 leagues of coast.—On some applications of elliptic functions (continued), by M. Hermite.—The Echidna of New Guinea, by M. Gervais. He notes several points in which the head differs from that of the Australian animal.—On invariants, by Prof. Sylvester.—On the waves of various kinds which result from the working of the sluice of Aubois, by M. Caligny.—On the solution of the equation of the fifth degree, by M. Brioschi.—Nature of the hydrocarbons produced by action of acids on manganesiferous spiegeleisen, by M. Cloez. Several of these products seem identical with those which exist in the ground and are extracted on a large scale under the name of petroleum. This production of complex carbonised compounds, without any intervention of life, supports the views of certain geologists on the origin of petroleum. The reproduction of a large number of organic species might be realised by commencing with ethylenic or formenic hydrocarbons, furnished by cast iron.—Discovery and observation of the planet 175 by Mr. Watson.—On the distances of stars, by M. Flammarion. He cites several facts which seem not to allow of basing on differences of brightness an estimate of distances.—On the intermediary integral of the third order of the equation with partial derivatives of the fourth order expressing that the problem of geodesic lines supposes an algebraic integral of the fourth degree by M. Levy.—Graphic tables and anamorphic geometry; reclamation of priority, by M. Lalanne.—Second note on the magnetisation of steel tubes, by M. Gaugain. The variations of magnetism produced by heat in a solid bar of steel are not different from those in a system composed of a tube and a core. Both seem to depend on the *inverse* magnetism developed by the mutual reaction of concentric layers, whether of the bar or of the system.—Liquefaction of bioxide of nitrogen, by M. Cailletet. This he effected by compressing to 104 atmospheres at − 11°. At + 8° the bioxide is still gaseous under 270 atmospheres. He hopes, also, to be able to liquefy formene. M. Berthelot remarked on the importance of this achievement, and thought it probable that most of the gases not yet liquefied, such as oxygen, which already diverges from Mariotte's law under great pressures, and oxide of carbon, would yield to M. Cailletet's new processes.—On nitrification by organic ferments, by MM. Schloesing and Muntz. Whenever, in these experiments, a nitrifiable medium has remained in the presence of chloroform, or has been heated to 100°, then guarded from dust, the nitrification has been suspended, but it has been possible to renew it, by introducing into the heated medium a minimum quantity of a substance like mould in process of nitrification.—On the termination of the nerves in tactile corpuscles, by M. Ranvier. He studied these organs in the tongue and bill of the domestic duck (where they are found in great simplicity). The tactile disc, the true sensitive nervous organ, is protected against mechanical excitations from without by the special cells surrounding it. It can only be impressed in an indirect way.—An experiment in *stasimetry* or measurement of the consistence of organs, by M. Bitot. The instrument is a kind of balance having at the end of one arm a perforating or sounding needle, at the end of the other a small controlling plate, and at the centre a pendulum with successive weights and a long indicator needle connected to it above, moving over a graduated scale.—On a modification of Bell's telephone, with multiple membranes, by M. Trouvé. A cubical chamber is substituted for the single membrane; each face of it is a membrane which, in vibrating, influences a fixed magnet with electric circuit. Associating all the currents generated, an intensity is obtained proportional to the number of magnets affected.—On the telephone, by M. Pollard. This describes some experiments at Cherbourg. M. Du Moncel called attention to the ideas expressed by M. Ch. B—— more than twenty years ago, and which contains the telephone in germ.—On a new sounding apparatus for works of coast hydrography, by M. Pinheiro.

HYDROPHOBIA

POPULAR alarm has of late been aroused by the publication of an unusual number of cases of death from this most terrible disease, and interest and hope have been excited by the statement that, at last, a drug has been found--curare--which does exert such an influence that at least one case is said to have been rescued from otherwise certain death. We propose to discuss briefly in this article the chief points in the natural history of hydrophobia, to examine what light, if any, science has thrown upon its nature, and to inquire what reasons there are for believing in the alleged efficacy of drugs in its treatment.

Hydrophobia is a disease which never occurs spontaneously in man, being invariably communicated to him by the bite of some animal affected with it—commonly by the dog, more rarely the cat, more rarely still the fox and wolf. The bite induces the disease by permitting the absorption of the saliva of the diseased animal, the peculiar poison or "*materies morbi*" of the disease being contained in the saliva. Inasmuch, then, as man only becomes affected with hydrophobia through the intermediation of the lower animals, it will be necessary to consider it, first of all, as it makes itself manifest in them.

It has been, and still is, a subject of dispute amongst veterinarians whether hydrophobia, or "rabies," was originated spontaneously in the dog. Avowedly the immense majority of cases of the disease can be proved to have been due to the bites of rabid animals; some cases do occur, however, in which it is stated that there was no possibility of contact with a diseased animal, and these are held to prove the occasional spontaneous origin of the disease. Now, whilst we are not prepared absolutely to contradict such a surmise, and to allege that at no time, and under no circumstances, hydrophobia originated spontaneously, we do hold that there is no better evidence of such a new origin *now* than there is of the spontaneous generation of the poisons which induce small-pox, scarlet fever, or measles. In the case of these diseases, as in that of hydrophobia, it does sometimes happen that some of the links in the chain of evidence are lost which are required to prove the connection between one case of disease and its precursor, but the exceptional cases do not outweigh the immense mass of evidence which proves that each of the diseases previously mentioned is as certainly the offspring of a previous case as is each animal or plant at present living the offspring of a pre-existing parent organism. We shall then probably be quite right in assuming that not only is it true of hydrophobia as it affects man, but of the disease as it is manifest in all animals, that it is always due to the inoculation of poison from a diseased into a healthy organism.

In commencing a description of hydrophobia we must point out that whilst the disease is always more or less prevalent, periods when it becomes much more frequent occur from time to time. Within the present century, especially between 1800 and 1830, several such outbreaks occurred; in this respect hydrophobia resembles other diseases of the zymotic class, which, though always more or less prevalent, only occasionally prevail with epidemic intensity. We must assume that at this period the circumstances which are required for the spread of the particular disease are specially favourable, though it is only rarely that we can do more than surmise what these special circumstances really are.

In the dog, as indeed in all animals, there is a period of latency, or as it is technically termed, of "incubation," which intervenes between the inoculation of the poison of hydrophobia and the development of any symptoms; this period varies remarkably: it may be as short as a week, or as long as three months; the greater number of cases occurring, however, between the twentieth and fiftieth days after the poisonous wound has been inflicted. It must not be supposed that the bite of a rabid dog always induces the disease in other dogs which it bites; a certain number of such bites prove abortive. Thus, out of 131 dogs which had been bitten by, or inoculated with, the virulent saliva of certainly rabid dogs, only sixty-three fell victims. The failures in these cases are to be explained in several ways. In some cases it is probable that the saliva was not active, just as sometimes the liquid from the vaccine vesicle, when fairly tested, is found to be incapable of reproducing vaccinia; in other cases the poisonous saliva has doubtless been prevented from penetrating the wound, having been retained by the hair and cuticle of the bitten animal; finally, in a third class of cases, it must be assumed that the bitten animal did not offer conditions required for the development of the disease. A case is, indeed, recorded, on the best authority, in which a pointer dog was caused to be bitten on seventeen separate occasions by dogs affected with rabies, without the disease being induced.

The period of incubation having passed, the first symptoms of rabies usually consist in a change in the temper of the dog, which becomes sullen and snappish, and which often bites those around it, even without any provocation. This prominence of the cerebral symptoms in the early stages of hydrophobia in the dog is very remarkable, and contrasts, as will be seen in the sequel, with the phenomena of the disease in man. It is evidenced not merely by the tendency to bite, but by the whole changed aspect of the animal, which is now observed to be obviously ailing. The appetite becomes capricious, food often being refused, and all kinds of rubbish swallowed, and often, though by no means invariably, the dog utters dismal howls. It is in this stage that the dog often wanders from home, and apparently under the influence of maniacal excitement, rushes on, biting all dogs which it meets, and often all human beings who happen to come in its way. It is to be noted that the dog does not exhibit any of the dread of water which is so painfully evident in the disease as it affects man; this depends upon the fact that in the dog there appears to be little, if any, tendency to spasm of the muscles of deglutition. As the disease advances palsy of the posterior extremities often occurs; in other cases a peculiar paralysis of the muscles connected with the lower jaw sets in, so that the suffering animal is unable to utter any sound, and is said to be suffering from "dumb-madness." Throughout the disease there is usually an increased secretion of viscid saliva. The

Vol. xvii.—No. 424

whole course of hydrophobia in the dog is run in from four to eight days, the majority of cases proving fatal about the fourth or fifth day. This short description of rabies or hydrophobia, as it affects the dog, is almost exactly applicable to the disease as it occurs in other domestic animals; a maniacal excitement and a tendency to injure men and animals with which they come in contact being as characteristic of herbivorous animals as it is of dogs, cats, foxes, and wolves.

Having, then, before us an outline of hydrophobia as it affects the lower animals, let us compare with it the disease as it is observed in man.

In the first place as to the frequency with which the bite of a mad dog is followed by hydrophobia. No general satement can be made on this matter, as the results vary very greatly according to the part bitten, according to the treatment to which the bitten part is subjected, &c. For instance, bites inflicted upon parts protected by clothing are followed by hydrophobia much less frequently than those in which the hand or face is injured, the poison in the former case being absorbed by the intervening clothing.

Next, as to the period of incubation. In man this varies even more than in the case of the dog; the majority of cases of human hydrophobia have, however, a period of incubation which varies between thirty and fifty days, though exceptional cases occur in which many months have elapsed between the infliction of the bite and the supervention of the symptoms; these remarks might be illustrated by reference to cases which have occurred in England, and which have been recorded in the medical journals during the last two years; the shortest period of incubation observed within this period having been eighteen days, and the longest nine months. During the period of incubation there is nothing to distinguish a bite inflicted by a rabid dog from the bite of a healthy dog. The study of some of the recorded cases of the disease would almost lead to the conclusion that in man there is during the period of incubation a tendency to nervous depression and melancholia which is a precursor of the terrible symptoms which are to follow; it is obvious, however, that great caution ought to be exercised in the interpretation of such mental symptoms, which are after all in many cases but the necessary and logical results of an injury of which the possible consequences are but too well known and correspondingly dreaded. If we except these symptoms of depression and melancholy there are no characteristic phenomena which intervene between the infliction of the bite and the onset of the attack of hydrophobia.

In a certain number of cases the advent of the disease is ushered in by pain of a neuralgic character in the bitten part; this appears to be merely an evidence of the general feeling of illness which then supervenes, rather than any evidence of the specific nature of the bite. More commonly the first phenomena are merely vague symptoms of feeling very unwell, accompanied often by an intense feeling of melancholy. A deep sighing character of the inspirations, or even paroxysmal attacks of difficulties of breathing, with some pain in the throat and pain in the præcordial region often follow. Beyond the feeling of impending evil, there is no mental symptom at this stage of the disease at all comparable with those observed in the lower animals. Next in the order of accession is the difficulty which the poor patient experiences in swallowing; this, at first slight, symptom soon acquires a terrible intensity; the patient is troubled by an agonising thirst, and yet dares not drink; any attempt to drink gives rise to a terrible spasm of the muscles engaged in deglutition, and apparently to a simultaneous spasm of the muscles engaged in inspiration so powerful that he dreads suffocation. An analysis of the symptoms at this stage leads one, indeed, to the opinion that swallowing is often dreaded because of, and is indeed impeded by, the spasm of the inspiratory muscles which it induces. Then follows a stage in which often, though by no means invariably, the patient becomes subject to delusions, and often violently maniacal, and this is succeeded by a stage of exhaustion and quiet which ushers in the fatal termination.

If we have sketched with some degree of minuteness the outlines of a very painful picture, we have done so because a knowledge of them was absolutely essential before we could attempt to consider what light science has thrown upon this dread disease, and what reliance is to be placed upon the remedies which have been suggested for its cure.

We shall now, in the first place, consider the results of pathological investigations relating to hydrophobia. Are there not some well marked and constantly present lesions of the great nerve-centres corresponding in some measure to the symptoms which manifest themselves during life? The older observations generally concur in showing that the brain and spinal cord are the seat of congestions which are, however, not sufficiently constant in their localisation to admit of any conclusions being drawn from them. And, since the time when pathological anatomy attained its present development and accuracy, but few persons sufficiently competent to draw accurate conclusions from their observations have had the opportunity of working at the subject. From the observations of Benedict (*Virchow's Archiv*, 1875), it resulted, that in addition to more or less widely spread congestion, there occur granular degeneration of nerve-cells, and of nerve-fibres in various parts of the brain. Subsequently Wassilieff, working under the direction of Prof. Botkin, of St. Petersburg, described (*Centralblatt f. d. med. Wissenschaft*, 1876, p. 625) *a*, some alterations in the nerve-cells of the medulla oblongata, the outlines and nuclei of which are indistinct and the contents cloudy; *b*, a large accumulation of corpuscles of the size of white blood-cells in the interstitial connective tissue of the brain, in the peri-vascular canals and immediately surrounding them; and *c*, the presence of a highly refracting substance in the peri vascular spaces, especially in the cortical layers of the cerebral hemispheres. Somewhat akin to them are the observations of Dr. Gowers who found in the medulla oblongata after death from hydrophobia, accumulations of cells, resembling white blood-cells, in the vicinity of the blood-vessels, and also in the nervous substance. But what do all these observations indicate? In all probability the accumulations of white cells are caused by the emigration of white blood corpuscles from the blood, so that they are to be held as supporting the older observations which alleged congestions of the brain to be frequently present, and the other pathological changes noticed by the three observers to whom we have referred, cannot as yet be adequately interpreted.

Pathological anatomy then helps us a little in our attempts to elucidate hydrophobia. Can we obtain better results by reasoning upon the symptoms and course of the disease from the standpoint of physiology? Hardly, but we may make the attempt. Physiology necessarily cannot help us to understand the nature of the peculiarly subtle poison which can lurk so long in the system without betraying its presence by any symptom, but she may help us in explaining the phenomena which it induces. Of this poison we know as little, if not less, than of the other poisons which are capable of inducing zymotic diseases. Each of those diseases appears to depend upon a definite *materies morbi*, upon the presence of which the peculiar phenomena of each depend; but the periods which elapse between the introduction of the poison and the manifestation of the disease varies in each case, no less than the course and duration of the disease, and the organs and tissues of the body which are affected. Thus, in scarlet fever the poison induces changes in the epitheliated surfaces of the body, manifested by the rash, the sore throat, the acute kidney affection; in typhoid fever anatomical changes of the most obvious nature are wrought in the alimentary canal, and lead to the special dangers of the disease; in typhus, again, the poison, whilst producing changes in the general nutrition of the body, and exciting a specially-marked action upon the brain proper (as evidenced by the marked affection of all mental processes), produces no typical anatomical changes. These diseases all illustrate the fact that the poison of each zymotic disease affects certain tissues and organs of the body, and it might be easily shown that it is by the implication of particular functions that each of these poisons *usually* induces death. Is there, in the case of hydrophobia, any evidence that it affects specially any particular organ of the body? Yes; a physiological analysis of the disease reveals the fact that its symptoms depend upon an affection of the nerve centres, and especially of the medulla oblongata.

These essential symptoms are—the spasmodic difficulty of breathing, which depends upon a spasm of the *inspiratory* mechanism and a spasmodic affection of the group of muscles engaged in deglutition. The nerve-centres which preside over respiration and the co-ordinated movements of deglutition are situated in the medulla oblongata, and it is these centres which appear to be peculiarly affected. The reflex excitability of this portion of the nervous apparatus becomes first of all heightened so that a stimulus applied to the mucous membrane of the gullet, which in health would give rise to a normal contraction of the muscles of deglutition, travelling on to the morbidly irritable medulla, throws the centre presiding over deglutition into a state of tonic spasm so intense as to be acutely painful; not confining its action to this one centre, the stimulus is able to throw the contiguous respiratory centre into a similar state of spasm, and the patient runs the risk of suffocation because the movements of the thoracic box, which are essential causes of the passage of air into and out of the lungs, cease for a time. The mechanism of suffocation in these cases resembles that observed when the upper end of the pneumogastric nerve is stimulated by a succession of strong induction shocks, except that in hydrophobia the abnormal effect is doubtless due not to the intensity of the stimulus, but rather to the heightened excitability of the nerve-centres implicated. Apparently a subtle animal-poison acting upon an intensely vulnerable but limited part of the nervous mechanism induces in it an action similar in kind to that produced by strychnia upon the spinal cord. Under the influence of this well known poison the excitability of the nerve-centres in the cord is heightened, so that a stimulus reaching it by an afferent nerve which would in the healthy unpoisoned condition lead to the reflex and painless contraction of but a small group of muscles, will be able to throw the nerve-cells of the whole cord into intense activity, and as a result occasion the characteristic and terribly painful convulsions of strychnia poisoning. There are, indeed, other facts besides those previously mentioned which point to a state of irritation and increased nervous excitability of the medulla and contiguous nerve-centres. Thus it has been observed that occasionally the pulse has been abnormally slow, a result almost certainly due in these cases to an excitation of the inhibitory centre in the medulla—of that centre which exerts a moderating or restraining influence upon the heart's action; further, it not unfrequently happens that towards the close of the hydrophobic stage, stimuli which were at first only capable of inducing the spasms of deglutition and inspiration, are able to bring on attacks of general convulsions. Here we have a still further extension of the effects of the irritation due to an extension of the reflex excitability from the medulla to the spinal cord.

Our analysis of the symptoms of hydrophobia reveals that as a rule the spasmodic stage terminates before death, which is not produced, as in strychnia poisoning, by the mechanical result of the convulsions—suffocation—but apparently by a more general, though we confess unknown, action of the poison on the organism generally. We know as little of the mode of death in this case as we do in that of scarlet fever, or diphtheria, or typhus, each one of which *may* produce death without leading to the anatomical results which, at any rate in the case of the two former of these diseases are their usual accompaniments. Zymotic poisons may indeed leave as few traces of their action as the simpler and better known poisons such as prussic acid or morphia, so that whilst we cannot disregard the local manifestations or changes which they induce, and which of themselves are a frequent source of danger, we must admit that they are in many cases—nay in most cases—secondary in importance to the more general phenomena which are the expression of the poisonous influence affecting the organism.

(*To be continued.*)

ANCIENT HISTORY FROM THE MONUMENTS

Ancient History from the Monuments. The History of Babylonia. By the late George Smith; edited by A. H. Sayce. *The Greek Cities and Islands of Asia Minor.* By W. S. W. Vaux. (Society for Promoting Christian Knowledge, 1877.)

THE Society for Promoting Christian Knowledge has been doing a very useful work in acquainting the public with the historical results of recent Oriental research in a cheap and handy shape. The work has been wisely placed in the hands of those who have themselves been pioneers in the task of discovery, and the reader has thus been secured against the errors and unfounded conclusions almost inseparable from second-hand information. The histories of Egypt, Assyria, and Persia, have now been followed up by those of Babylonia and Asia Minor, and the fact that the history of Babylonia was the last literary work which Mr. George Smith, the indefatigable Assyrian explorer, lived to accomplish, gives a melancholy interest to it over and above that of its subject matter. Indeed, the materials for reconstructing Babylonian history are still but scanty, and must remain so until systematic excavations can be made among the buried cities and libraries of ancient Chaldea. With the exception of a few early bricks and a few dedicatory inscriptions of Nebuchadnezzar and his successors, it is from the clay tablets of Nineveh that almost all our knowledge of the sister kingdom has been derived. Even Babylonian chronology is still in an uncertain and tentative condition, and the fragments of the Babylonian historian, Berosus, help us but little. Whole periods must still be left blank, and though one or two dates, like the conquest of the Elamite king, Cudur-nankhundi, in B.C. 2280, can be fixed by the aid of later monuments, the relative position of even whole dynasties has not yet been settled. Our acquaintance with the mythical epoch is quite as great as with the historical epoch; the Assyrians preferred the legends of the rival monarchy to a record of its glories, and while, therefore, we now have in detail the stories of the creation, of the flood, or of the hero Izdubar, we know comparatively little of the political changes which passed over the Babylonia of history. Compared, however, with what we knew of them a few years back, even this limited knowledge seems large and accurate, and the best evidence of this is the volume which Mr. Smith has written, and which would have been an impossibility but a short time ago. Those who wish to learn what light has been thrown by cuneiform discovery on this important section of ancient history cannot do better than refer to his book. The importance of Babylonia for the history of culture and civilisation is daily becoming more manifest; the early Accadian population of the country, who spoke an agglutinative language and invented writing, left a rich inheritance of art, science, mythology, and religious ideas to their Semitic successors, and through them to the Jews and Greeks. The latter were influenced partly through the Phœnicians, partly through the nations of Asia Minor. Mr. Vaux's volume on the Greek cities of Asia Minor is therefore a suitable companion to Mr. Smith's "History of Babylonia." His difficulty in compiling it must have been the converse of Mr. Smith's, as here it was not the meagreness but the superabundance of materials which was likely to cause embarrassment. His selection, however, is good and judicious, and the book he has produced is at once instructive and readable. He has not forgotten to invoke the assistance of the latest discoveries; the first few pages are devoted to an account of Dr. Schliemann's life and discoveries, and the researches of Newton, Wood, and Fellows, have been largely drawn upon. Considering the space at his command, Mr. Vaux must be congratulated upon the amount he has been able to cram into it, and, so far as we can see, no city or fact of importance has been omitted. Both volumes are appropriately illustrated, and the "History of Babylonia" contains a copy of a bronze image of an ancient Chaldean monarch recently brought to the British Museum, and interesting on account of the rarity of such early monuments. Their value is further increased by the addition of indices, and the editor of Mr. Smith's volume has added a chronological table of the Babylonian kings, and an explanatory list of proper names.

FRENCH POPULAR SCIENCE

Musée Entomologique Illustré. Les Papillons: Organisation, Chasse, Classification. 80 Plates and 260 Woodcuts. *Les Coléoptères: Organisation, Mœurs, Chasse, Collections, Classification.* 48 Plates and 335 Woodcuts.

Anatomie et Physiologie de l'Abeille. Par Michael Girdwoyn. 12 Lithographic Plates.

Les Champignons. Par F. S. Cordier. 60 Chromolithographs and 8 Woodcuts.

Les Prairies Artificielles. Par Ed. Vianne. 127 Woodcuts.

Les Ravageurs des Forêts et des Arbres d'Alignement. Par H. De la Blanchère. 162 Woodcuts.

Les Ravageurs des Vergers et des Vignes; avec une Étude sur le Phylloxera. Par H. De la Blanchère. 160 Woodcuts.

Le Chalumeau. Analyses Qualitatives et Quantitatives. Guide Pratique. Traduction libre du Traité de B. Kerl. Par E. Jannettaz.

Les Aliments. Determination Pratique de leurs Falsifications. Par A. Vogl. Traduction par Ad. Focillon. 160 Woodcuts. (All published by J. Rothschild, Rue des Saints-Pères, Paris.)

WE have received the preceding batch of works from the house of Rothschild of Paris. This is not the first time we have been able to show not only how worthily M. Rothschild is maintaining his position as one of the first publishers of popular science works of the time, but how eagerly such works are read, and how highly they are appreciated in France. It is impossible to speak too highly of the honest work which has been put into each of the volumes, while many of them are written by men whose names are widely known on this side the Channel. As is proper in this style of literature, the text is equalled by the illustrations. Why is it that in the matter of illustrated books such as those before us, the French finished product is so far superior to nine-tenths of those published on this side the water? Nothing can exceed the perfection of many of the hundreds of woodcuts in the above volumes, while we have rarely seen more finished specimens of chromolithography than those to be found in some of the volumes.

We cannot think that the French public is so far beyond our own in its appreciation of science, as to make the publication of similar works in our own country hopeless. We shall therefore give an analysis of each of the above works in a single article, with a view of showing the treatment adopted abroad in popularising the branches of science with which the volumes deal, instead of devoting one to each of them in turn, which we should have been quite justified in doing, having regard to their value.

Of the two volumes on the Natural History of Insects, which are published by a society of French and foreign entomologists, vol. i. is devoted to the Coleoptera, and comprises their organisation and their different orders, with a short description of each, and woodcuts showing their different stages of development. These are followed by other useful matter, and then, in the second part, we come to "Le Monde des Scarabées." The stag-beetle is here taken as an example of his family to show the anatomy of these insects. The description of their dwellings and instincts is clear, and written in such a style that it may be understood and enjoyed by those not versed in entomology. This part occupies a good portion of the book. In the pages devoted to the hunting, preparing, and keeping of beetles, beginners may find every information they require; pincers, pins, and nets are all shown, as well as the necessary requisites for the knapsack. A list of the principal entomological works is given, after which we have a lengthy classification and iconography of European coleoptera, illustrated with forty-eight plates beautifully coloured by hand.

The arrangement of volume ii., on Butterflies, is very similar to the above, and contains thirty coloured plates illustrating the butterfly, caterpillar, and chrysalis, together with the plants on which these are most frequently to be found.

"The Anatomy and Physiology of the Bee," is taken from volume vi. of the "Memorials of the Polish Society of Exact Sciences in Paris," and translated into French by M. Pillain. This work consists of twelve lithographic plates which obtained medals of merit both at the Universal Exhibition at Vienna and from the Royal and Imperial Society of Agriculture of Cracow. On these plates we have 172 figures of the various parts of a bee, greatly magnified. It is scarcely necessary to add that these are extremely well finished. In the folio we have the memoir itself, a book of forty pages, which first introduces us to the bees of different countries and the bibliography of the subject. In chapter i. the author describes the exterior parts of the bee, and in the second and third the interior and more complicated, such as the muscles, nervous system, circulation of the blood, &c. The work terminates with explanations of the figures. Altogether this is a valuable addition to an entomologist's library, and does great credit to the society from which it has emanated.

In M. Cordier's book on Fungi we have much valuable information. In the first place he treats generally of the organisation of fungi, their physiology, mode of reproduction, and geography, how to distinguish the edible from the poisonous, and he shows us how to extract this poison; he tells how this works on the animal economy and the best means of counteracting it. In the second part all the fungi useful to man are chronicled, with detailed descriptions of each order and drawings from nature.

M. Cordier has adopted Persoon's classification in preference to any other, as he takes it to be more practical; indeed he dedicates the book to his memory as the "Créateur de la Science Mycologique." The drawing and colours of the sixty chromolithographs are well worthy of note. The book also contains a glossary, able of common, and one of the scientific, names of the ungi.

The author has evidently endeavoured to make his subject as interesting and complete as possible. The style of the popular portion of the book is admirable, and *n vivants* will be glad to be informed that there are eight pages dealing with the proper way of cooking truffles.

The two small books by H. de la Blanchère—one on the enemies of forest trees, with 162 engravings of insects and larvæ, the other on the enemies of orchards and vines similarly illustrated, form part of a large series now well known and highly appreciated in France. We have already noticed some of them, and these are in no way nferior to the former ones.

"Plants used for Food," written by A. Vogl, of Prague, translated into French by Ad. Focillon, is a practical guide for detecting the adulteration of flour, coffee, chocolate, tea, and the like.

"The Blowpipe," by E. Jannettaz, is extremely well arranged, and is a thoroughly practical guide for engineers, mineralogists, &c.; the information is accurate and condensed, and M. Jannettaz's name is a guarantee of its scientific value.

OUR BOOK SHELF

The Fifth Continent, with the Adjacent Islands, being an Account of Australia, Tasmania and New Guinea, with Statistical Information up to the Latest Date. By C. H. Eden. With Map. (London: Society for Promoting Christian Knowledge; no date.)

THIS volume contains much information on the Australian colonies, but it is somewhat desultory and incomplete. It is not a children's book, and it will not satisfy those who are in quest of full information on the subject. It affords some idea of the history, people, and products of Australia and New Guinea, but it would be better to cut out much of what is said about the history and the people and give more space to well-digested information about the resources of the countries.

Notes by a Field Naturalist in the Western Tropics. By Henry H. Higgins, M.A. (Liverpool: Edward Howell, 1877.)

THIS is a readable record of observations made during a yacht voyage to the West Indies by Mr. Higgins, who is president of the Liverpool Naturalists' Field Club. Mr. Higgins went over well-trodden ground, and therefore we need not look for any novelties in this little volume, although much of it is interesting. The chief purpose of the voyage, undertaken by Mr. Cholmondley, the owner of the yacht, was to observe and collect tropical birds. Mr. Higgins collected, also, many specimens, both zoological and botanical, from sea and land, which are now being arranged. He may possibly, he states, publish an account of the biology of the voyage.

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.

The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.]

The Radiometer and its Lessons

PROF. FOSTER'S clear representation of what he conceives to be the effect of rarefaction reduces the question between us to a definite issue.

Having assumed that heat is flowing across an intervening layer of gas from a hotter surface A to a colder surface B, he says:—"Then, I imagine, the flow of heat through the gas will take place *as though* there were, in contact with each solid surface, a layer of gas whose temperature is throughout the same as that of the contiguous solid, and whose thickness is equal (or at least proportional) to the mean length of path of the molecules." Without these layers of uniform temperature or whatever may produce an equivalent effect it follows directly from Prof. Foster's reasoning that the rate at which heat is communicated is, as I maintain it is, independent of the density, whereas *if there were* any such layers I should at once admit the force of Prof. Foster's reasoning. The whole question turns therefore on the existence of these layers of uniform temperature.

Now what evidence of such layers have we? No experimental evidence certainly; and not only has the kinetic theory not as yet been applied to explain their existence but it is easy to demonstrate that according to this theory no such layers or any equivalent can exist. For in order that the condition of heat may remain unaltered it is necessary that the rate at which heat is transmitted across all surfaces parallel to the solid surfaces which can be drawn through the gas should be the same. And the rate at which heat is transmitted is for small variations of temperature proportional to the degradation of temperature, hence if there were a layer of uniform temperature no heat could be transmitted.

It is surely incumbent on Prof. Foster in assuming the existence of these layers to give some sort of proof in support of his assumption, but not one word does he say!

I cannot allow this to pass without pointing out that the description which Mr. Stoney has given of my view is grossly wrong and is certainly not to be gathered from anything I have written. Mr. Stoney carefully turns my position. He makes out that I have explained the action in question as *arising* from *convection currents*, whereas I have from first to last maintained that it is these currents which oppose and eventually overcome the action. He makes out that my theory takes no account of molecular motion, whereas, in truth, it takes no account of anything but molecular motion, the effect of the expansion of the gas being so obviously trivial that I have never even mentioned it.

Your readers may judge of this by comparing the first of the following quotations, which is from Mr. Stoney's letter, with the others which are from my own papers, and are the only expressions, not mathematical, which I have given of my views as to action in the question:—

Mr. Stoney's.	*My Own.*
"Prof. Osborne Reynolds's explanation is based on the fact that when a disc with vertical sides is heated on one side and exposed to a gas, a convection current sets in, which draws a continuous supply of cold gas into contact with the hot surface of the disc. As this cold gas reaches the disc it is expanded, and thus its centre of gravity is thrown further from the disc. Accordingly, the disc, if freely suspended, will move in the opposite direction so as to keep the centre of gravity of the gas and disc in the same vertical line as before, and, if not freely suspended, will suffer a pressure tending to make it move in that direction. If I have understood Prof. Reynolds aright, this is both a correct and full description of his explanation as last presented."	"Whenever heat is communicated from a hot surface to gas, the particles which impinge on the surface will rebound with a greater velocity than that with which they appropriate; and consequently the effect of the blow must be greater than it would have been had the surface been of the same temperature as the gas. "And, in the same way, whenever heat is communicated from a gas to a surface, the force on the surface will be less than it otherwise would be, for the particles will rebound with a less velocity than that at which they approach.[1] "These forces arise from the communication of heat to or from the surface from or to the gas. These forces will be directly proportional to the rate at which the heat is communicated; and since this rate has been shown by Prof. Maxwell to be independent of the density of the gas, these forces will be independent of the density of the surrounding medium, and their effect will increase as the density and convection-currents diminish."[2]

The first of the quotations from my papers is followed by a mathematical expression on which I have depended for completeness, and from this expression, in which neither convection currents nor the expansion of the gas have any place whatsoever, it follows that whenever heat is steadily diffusing *into* or *through* a gas, the momentum transmitted across any surface in the direction in which the heat is diffusing will be greater than that transmitted in the opposite direction by a quantity proportional to the rate at which the heat diffuses, divided by the square root of the absolute temperature of the gas.

As to the value of what follows in Mr. Stoney's letter, I must leave it to your readers to decide. He proceeds to claim that his own theory has the advantage of being based on molecular motions, he says:—

"My explanation, on the other hand, is based on *molecular* motions which go on in the gas without causing any molar motion, and is independent of convection currents."

Then having thus attributed to me an explanation, I never even thought of offering, and having assumed the true base of my theory as alone belonging to his, he proceeds to show wherein I am wrong. And in every subsequent position which he attributes to me, he is as wrong as he is in his first statement.

Under these circumstances it would be useless for me to enter upon questions as to how far "diffusion," according to the kinetic theory may be more "sluggish" than Mr. Stoney's "penetration," or to discuss further the possibility of his "Crookes's layers."

In my last letter I showed that the condition of a gas which Mr. Stoney called a "Crookes's layer" was impossible, and I do not see that Mr. Stoney has improved his position by showing that he had arrived at the possibility of the condition by making the false assumption "*that gas is a perfect non-conductor of heat.*"

Wherein Mr. Stoney's views are at variance with the results of the laborious investigations of Maxwell, Clausius, Thomson, and others, he may best convince himself by referring to the works of these authors. Until he has read my papers and explained the discrepancies between his views and the generally-accepted laws of gases, I do not see that we have any common ground for discussion.

OSBORNE REYNOLDS

November 30

Mr. Crookes and Eva Fay

If Mr. Wallace had read my letter in NATURE of November 29 with a little more attention, he would have seen that I did *not* refer to the *Daily Telegraph* "as an authority in a matter of scientific inquiry," but that the account I gave of Mr. Crookes's "scientific tests" was given *in Mr. C.'s own communication to the 'Spiritualist,'* which would have been reproduced without abridgment if the columns of NATURE could have admitted it.

What I hold myself pledged to show (in NATURE, if it pleases, as well as in the new edition of my Lectures) is that the "tying-down by electricity" described by Mr. Crookes in the *Spiritualist*, is no more effective in preventing the performance of juggling tricks than Eva Fay's *ordinary* tying-down under which her tricks were publicly reproduced two years ago by Messrs. Maskelyne and Cooke. And since Mr. Crookes made no mention of the *extraordinarily* sensitive galvanometer he used, which is described for the first time by Mr. Wallace in the last number of *Fraser*, I only consider myself bound to show the *method* by which, with *ordinary* apparatus, the electric test may be evaded—the trained skill of the acute *trompeuse* being very probably required to meet the more severe test now first specified.

Mr. Wallace seems to me to have been a little hasty on another point. "The supposed *exposure* of Eva Fay in America," he says, "was no exposure at all, but a clumsy imitation." As this is merely Mr. W.'s *dictum* founded upon an imperfect newspaper report, I prefer to trust the judgment of the eye-witnesses who have publicly testified to *the completeness of the exposure*. Among these are not only three of the ablest men in New York (the Rev. Dr. Bellows, Ex-Surgeon-General Mott, and Dr. Hammond), but the reporters of the very newspaper referred to which had previously shown a decided leaning to the claims of spiritualism. And their judgment is confirmed by the fact (which Mr. Wallace probably considers as a newspaper fiction, but of which I have independent testimony) that *Eva Fay was forced by the local authorities to take out a licence as a juggler* as a condition of the continuance of her public performances.

The fundamental difference between Mr. Wallace and myself as to the validity of testimony in regard to the "occult" comes out so strongly in this case that we have really no common ground for a discussion which I cannot consider it profitable to continue. WILLIAM B. CARPENTER

The Glacial Geology of Orkney and Shetland

OWING to an accident I did not see your number of September 13 containing my letter on the glacial geology of Orkney and Shetland and Prof. Geikie's article (vol. xvi. p. 414), until my return from Scotland a few days ago. Otherwise I should have troubled you sooner with a few observations thereon.

In the first place I wish to thank Prof. Geikie for the very courteous manner in which he has referred to the remarks of an outsider who has ventured to intrude on what the Professor has made, to such an extent, his own peculiar province.

In the next place I am glad to find that upon what was the most important fact in my statement, viz., the absence of raised beaches or other signs of recent elevation of the land in Orkney, Prof. Geikie agrees with me.

I call this the most important because it bears directly on the theory of wide-spread changes in the relative level of sea and land owing to secular causes, such as a change in the axis of the earth's rotation, or in the position of its centre of gravity. If it can be proved that the difference of level, which caused the raised beaches of the south of Scotland, and extended north along the coast of Ross and Sutherland, dies out as we proceed further north, and disappears altogether in Orkney and Shetland, it is truly a crucial experiment which shows that these raised beaches are due to local elevations of the land, and not to a general sinking of the sea.

This is the conclusion to which Prof. Geikie points, though he naturally finds it difficult to understand why the upheaval, so marked in Sutherland, did not affect Caithness and Orkney.

I believe I can add a few facts which may assist in removing these doubts.

At one of the places in Caithness mentioned by Prof. Geikie, where the existence of a raised beach might be possible, viz., in the sheltered Bay, between Freswick and Wick, I believe there is one, though less strongly marked and at a lower elevation than those in similar situations in Sutherland. I allude to a terrace which bounds the links of Keiss Bay, about half a mile inland from the present coast-line. I cannot speak positively, not having seen it for some years; but my recollection is that it is a perfect miniature reproduction of the terraces round Brora and other bays in Sutherland. If so, it is a positive proof that the elevation of the land died out towards the north, and we might reasonably suppose that somewhere about the line of the Pentland Firth was the neutral axis, on one side of which the land rose, while on the other it fell.

Be this as it may, the *fact* is, I think, incontrovertible that Orkney did not share in the southern movement of elevation. This rests not only on the absence of raised beaches, forming terraces, which might possibly have disappeared, but still more on the absence of all traces of marine action, such as pebbles, sand, or shells, on the low plains which must have been submerged.

I would ask Prof. Geikie to consider whether the single instance of the Loch of Stennis is not conclusive. If the sea had ever stood twenty or thirty feet higher relatively to the land than it now does, the whole plain up to the hills must have been a sheltered, shallow, inland fiord.

As the land rose to its present level this must have left not only a terraced beach at the foot of the hills, which might possibly have disappeared (though it is hard to see why it should have done so in such a sheltered situation), but the whole plain must have been a raised sea-bottom, strewed over with pebbles, sand, and shells. These could not have disappeared, and as they are nowhere visible and the plain consists everywhere of the ordinary rock, with a thin mantle of soil resulting from its disintegration by ordinary atmospheric causes, I am, I think, justified in assuming it to be proved that Orkney did not share in the recent movement of elevation which affected the rest of Scotland.

Now one word as to glaciation. I can assure Prof. Geikie that I do not think for a moment of setting my authority against his, and that if he is right in the instances of glaciation he tells us he has observed in Orkney, so far from being disappointed, I shall be pleased, for it will clear up what has long seemed to me a perplexing anomaly.

Of course Orkney must have experienced the full rigour of the glacial period, and it is only natural to expect that it should show the same abundant signs of glaciation as the adjoining counties of Scotland. Prof. Geikie will therefore excuse me if I still retain a little of that healthy scepticism which is so conducive to the establishment of truth, and venture to plead that judgment may be suspended until there is further evidence. I do so mainly because the Professor's own statement is that during his visits to Orkney his attention was devoted mainly to the old red sandstone, and his remarks on glaciation were only incidental. Now there are some proofs of glaciation which are so obvious that there can be no mistake about them, others which may easily be mistaken, and which require close examination by a practised eye directed specially to them, to arrive at a just conclusion.

Boulders of foreign rock, perched blocks, rocks unmistakably rounded and polished by the ice plane, are among the former. But striæ require great practice and careful examination to be sure of them in a district of finely laminated sandstones which weather constantly into parallel lines or grooves. Stony clay again, from disintegrated rock, is often so like boulder clay that it requires close observation to distinguish one from the other. And finally where steep hills have crumbled away and filled up many places in the narrow valleys between them with their *débris*, as at Hoy, the appearances are very like those of glacial moraines.

Now I observe that nearly all the conclusive proofs of glacial action are wanting in Prof. Geikie's enumeration. He has not seen, or heard of anyone who has seen, a single boulder or perched block, or even a single piece of foreign stone in Orkney.

As regards boulder-clay I would join issue on his instances, taking especially that of Kirkwall Bay, because it is typical of the other cases and so easily accessible that the facts can readily be verified.

I believe it to be disintegrated and not boulder clay, for the following reasons:—

1. The clay is not compact like that of genuine boulder-clay, but of looser structure, and often clearly made up of minute splinters of the disintegrated rock.

2. The stones in the clay are never foreign stones, and are not scattered irregularly, as if shot out into a huge rubbish heap, as in true boulder-clay, but arranged for the most part so that the original lines of stratification can be followed.

3. If the section which resembles boulder-clay be followed up, it will be found to merge insensibly in what is unmistakably the common disintegrated surface soil of the district.

There only remains the question of *roches moutonnées*, and here I speak with the greatest diffidence, for certainly Prof. Geikie ought to know a great deal better than I whether a hummock of rock is or is not "admirably ice-worn and striated" like those behind Stromness.

I can only say that I have looked at them often, and they appear to me to be very different from the *roches moutonnées* of which I have seen so many in Scotland, Wales, and Switzerland. They are not rounded, smooth, and polished, as if planed into shape by some gigantic tool, but simply irregular hummocks of rock, sometimes smooth and sometime rough, according to accidents in the bedding and weathering of the strata. So at least they seem to me, and even in the valleys of Hoy, where, if anywhere, there were local glaciers, the sections shown by the small streams and low coast-line, always, I believe, exhibit the same appearance of sandstone strata, coming at an angle to the surface, and with their edges not planed off, but passing gradually into surface soil by disintegration.

Of course I make these statements subject to correction. It may be that I have failed to see things because my eye is not sufficiently educated. But when we couple what is, I believe, absolutely certain, viz., the absence of the more prominent and obvious proofs of glaciation in the form of boulders and foreign rocks, with the equally certain fact that Orkney was an exception to the general rule of recent elevation, I think Prof. Geikie will admit that the interests of science will be promoted by my remarks which may lead to reasonable doubts, and therefore to conclusive investigation, as to the fact whether Orkney does or does not give proof of having been covered by a great polar ice-sheet during the glacial period. S. LAING

36, Wilton Crescent, S.W.

Explosions

I HAVE been waiting to see if Mr. Galloway's paper on "Explosions in Mines" published in NATURE, vol. xvii. p. 21, would lead to any correspondence. Your readers may be interested in an incident reported to me by the late Dr. Böttinger, of Messrs. Allsopp's brewery, Burton-on-Trent.

In their new brewery, near the railway station, the crushed malt is lifted from one floor to another by a series of cups revolving on a leathern band. The casing, which incloses the band, is full of floating malt dust while the revolution is going on, and on opening one of the doors of the casing a puff of malt-dust is sent out into the room. Soon after the brewery was opened, a workman went with an undefended light to make some examination of the working of the leathern band, and on opening the door of the casing an explosion followed; not of a very serious character, but enough, I think, to throw the band out of gear. The cause of the explosion is evident; the rapid combustion of the fine malt dust with which the air puffed out into the room was charged.

Dr Böttinger died a few years since, but it would probably not be difficult to get accurate details of the accident from Messrs. Allsopp and Sons. A. MACKENNAH

Bowdon, December 11

Means of Dispersal

IN his great work, "Insecta Maderensia," Mr. Wollaston remarks upon the great affinity in the coleopterous fauna of Madeira with that of Sicily, and in his "Coleoptera Hesperidum," on the *northern* character of that of the Cape Verde Isles. Mr. Andrew Murray also found that out of 275 Cape Verde species 91 were common to the Canaries and 81 to the Maderian group. The last author would seem to rely on the efficacy of now submerged continents as a means of transmission between the two areas.

Towards the end of the fifteenth and commencement of the sixteenth century, the Portuguese carried the sugar-cane from Sicily to Madeira and the Canaries. The means of introduction would probably be the same then as now; the young shoots of cane would be conveyed in boxes or baskets of earth from one locality to the other, as the writer once carried young cane plants from Car Nicobar *viâ* Rangoon to Penang, and has seen the same arrive in the last locality from the West Indies. There can be little doubt that many of these plants must have been carried from Sicily to the Atlantic Isles before a successful or sufficient introduction was made, and with the earth in which the plants were conveyed, many geodephagous and other coleoptera would find an enforced means of migration. The sugar-cane is also reported as having been introduced into Cyprus from Asia, and transplanted from there to Madeira, thus adding another link to the localities in which these coleopteral affinities have been detected.

It is not proposed that this was the sole, but only a probable means of the transmission of common forms in the coleopteral faunas of these widely-separated districts. The number of causes which have been factors to the same in the past may be in an inverse ratio to our knowledge of them. W. L. DISTANT

Supplementary Eyebrows

I MET a gentleman a few days ago who has on either side of the forehead a supplementary eyebrow branching off from the superciliary ridge near the supra-orbital notch, and passing obliquely upwards and outwards for about ¾ inch across the forehead. Beneath these brows, which contain large and coarse hairs, are lines of soft down-like hair, one on either side occupying the usual position of the eyebrows. Since my attention was drawn to this subject I have noticed that many persons have a short secondary spur of hairs at the points indicated. Artists, I believe, have noticed this deviation from the normal eyebrow-line, as we occasionally observe it in portraits of Puck and other mischievous sprites.

There is a spot about midway between the orbits in animals that I have examined (namely, horses, dogs, and cats), whence the lines of hair-insertion into the skin radiate in various directions. If we consider the secondary eyebrows of man as a reversion to an ancestral type, we must conclude that our hairy progenitors also possessed such a radiating point of hair insertion upon their foreheads, and that the secondary eyebrows are only remnants of a hairy covering which originally enveloped the whole face. W. AINSLIE HOLLIS

Brighton

Diffusion or Cohesion Figures in Liquids

WITH reference to the above, allow me to relate some experiments made several years ago, and easily repeated.

1. Take a tall precipitate glass, fill it with water, drop into it a piece of lump or refined sugar and four or five grains of common salt. Let the vessel remain quiet, so that when the sugar is dissolved there may be different densities in the fluid from top to bottom. Then lightly touch the surface with a piece of lunar caustic (silver nitrate), and observe the figure which results.

2. The experiment may be repeated with sugar, diluted sulphuric acid, and barium chloride, the figures varying with the proportions of the ingredients used.

3. Take a common tumbler glass filled with water, dissolve in it half a tea-spoonful of common salt. Touch the surface of the solution with the point of a pen filled with ordinary black ink, and the characteristic figures are produced. F.R.S.

Brighton, December 12

Meteor

AT 8h. 13m. (± 2m.) P.M. on December 9, a brilliant meteor passed from 32 Camelopardalis (± 1°) through μ Lyræ (± 1°), and disappeared about 6° beyond; time of passage, 1·6 (± ·3) sec.; mag., 8 (± 2) χ Lyræ; colour, emerald green; track, yellow, visible 1 second; seen from 51° 24′ 43″ N., 2′ 13″ E. This may enable a northern observer to fix the position.

Bromley, Kent W. M. F. P.

ON THE CAUSATION OF SLEEP

THE last number of *Pflüger's Archiv* (vol. xv., p. 573) contains the following interesting note by Dr. Strümpell:—

"In the autumn of last year there was received into the medical clinik of Leipzig a youth, aged 16, in whom various phenomena of anæsthesia gradually developed themselves to an extent which has very rarely been observed. The skin of the whole surface of the body was completely insensible, and that in respect to every kind of sensation. The most powerful electric current—a burning taper held to the skin—was not able to produce any pain or even a sensation of touch. Almost all the accessible parts of the mucous membrane of the body exhibited the same insensibility to pain. Also all those sensations which are classed together under the name of 'muscular sense,' were entirely absent. The patient, when his eyes were closed, could be carried about round the room, his limbs could be placed in the most inconvenient positions without his being in any way conscious of it. Even the feeling of muscular exhaustion was lost. In addition there came on also a complete loss of taste and smell, amaurosis of the left eye, and deafness of the right ear.

"In short, here was an individual whose only connection with the outer world was limited to two doors of sense—to his one (right) eye, and his one (left) ear. Moreover, both these remaining doors could at any time be easily closed, and in this way it was possible to investigate the consequences of completely isolating the brain from all external stimulation through the senses. I have frequently made the following experiment, and often showed it to others:—If the patient's seeing eye was bandaged and his hearing ear was stopped, after a few (usually from two to three) minutes the expression of surprise and the uneasy movements which at first showed themselves ceased, the respiration became quiet and regular; in fact the patient was *sound asleep*. Here, therefore, the possibility of artificially inducing sleep at any time in a person simply by withholding from the brain all stimulation by means of the senses was realised.

"The awakening of the patient was as interesting as the sending him to sleep. He could be awakened by an auditory stimulation, as, for example, by calling into his hearing ear or by visual stimulation, by allowing the stimulus of light to fall upon his seeing eye; but he could not be woke by any pushing or shaking. If he was left to himself he did eventually wake up of his own accord in course of the day, after the sleep had lasted many hours, the awakening being due, it might be, to intrinsic stimuli started in the brain, or it might be to slight external unavoidable stimuli acting through his still functional sense organs, and making themselves felt in consequence of the sensitiveness of the brain being increased during the repose of the sleep."

THE MODERN TELESCOPE[1]

II.

WHETHER the telescope be of the first or last order of excellence, its light-grasping powers will be practically the same; there is therefore a great distinction to be drawn between the illuminating and defining power.

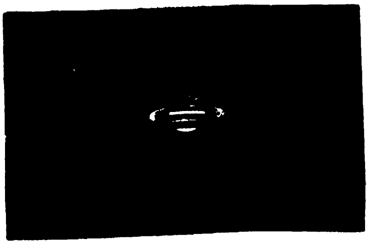

Fig. 5.—Saturn and his moons (general view with a $3\frac{3}{4}$ inch object-glass)

The former as we have seen depends upon size (and subsidiarily upon polish), the latter depends upon the accuracy of the curvature of the surface.

If the defining power be not good, even if the air be perfect, each increase of the magnifying power so brings out the defects of the image, that at last no details at all are visible, all outlines are blurred or stellar character is lost. Even with the best telescopes the power should not be strained.

The testing of a glass therefore refers to two different qualities which it should possess. Its quality as to material and the fineness of its polish should be such that the maximum of light shall be transmitted. Its quality, as to the curves, should be such that the rays passing through every part of its area shall converge absolutely to the same point, with a chromatic aberration not absolutely *nil*, but sufficient to surround objects with a faint violet light. With the reflector we have to consider the brilliancy of the surface and the perfection of curvature.

In close double stars, therefore, or in the more minute markings of the sun, moon, or planets, we have tests of its defining power; and if this is equally good in the instruments examined, the revelations of telescopes as they increase in power are of the most amazing kind.

A $3\frac{3}{4}$-inch suffices to show Saturn with all the detail shown in Fig. 5, while Fig. 6 shows us the further minute structure of the rings which comes out when the planet is observed with an object-glass with an aperture of 26 inches.

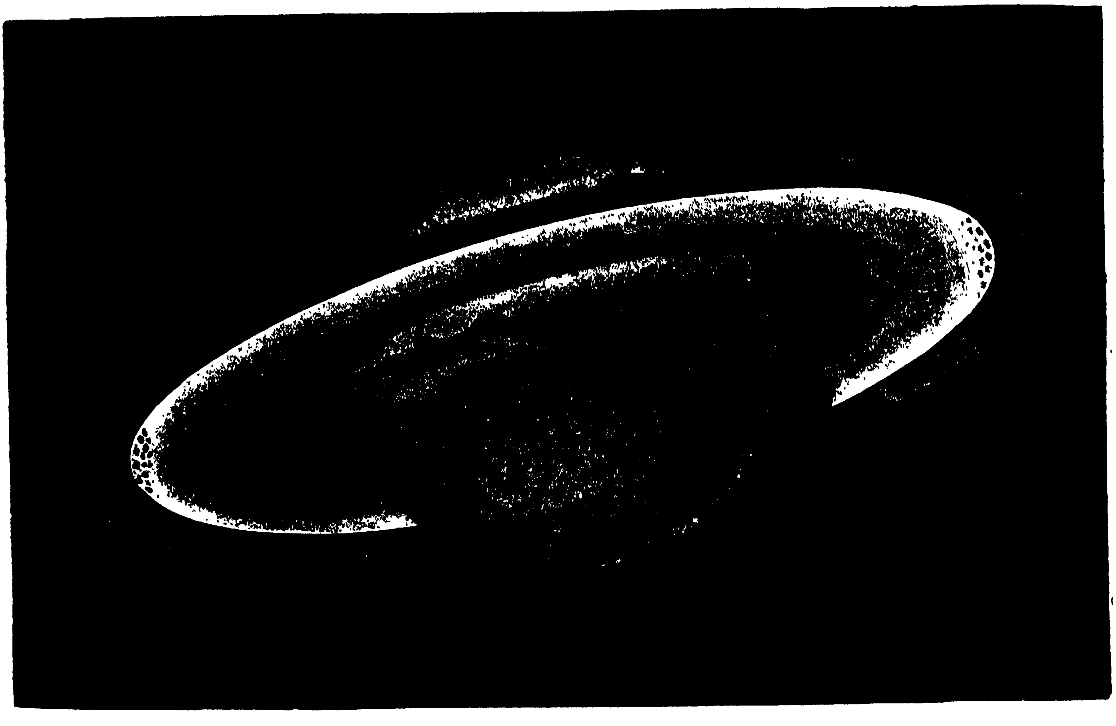

Fig. 6.—Details of the ring of Saturn observed by Trouvelot with the 26-inch Washington Refractor.

In the matter of double stars, a telescope of 2 inches aperture, with powers varying from 60 to 100, should show the following stars double:—

Polaris.
α Piscium.
μ Draconis.
γ Arietis.
ρ Herculis.
ζ Ursæ Majoris.
α Geminorum.
γ Leonis.
ξ Cassiopeæ.

A 4-inch aperture, powers 80–120, reveals the duplicity of—

β Orionis.
ϵ Hydræ.
ϵ Boötis.
Leonis.
α Lyræ.
ζ Ursæ Majoris.
γ Ceti.
δ Geminorum.
σ Cassiopeæ.
ϵ Draconis.

A 6-inch, powers 240–300—

ϵ Arietis.
32 Orionis.
λ Ophiuchi.
20 Draconis.
κ Geminorum.
ι Equulei.
ζ Herculis.
ζ Boötis.

An 8-inch—

δ Cygni
γ^2 Andromedæ.
Sirius.
19 Draconis.
μ^2 Herculis.
μ^2 Boötis.

The "spurious disk," which a fixed star presents, as seen in the telescope, is an effect which results from the passage of the light through the circular object-glass, or its reflection from a circular mirror; and it is this appearance which necessitates the use of the largest apertures in the observation of close double stars, as the size of the star's disk varies, roughly speaking, in the inverse ratio of the aperture.

---

[1] Continued from p. 68.

In our climate, which is not so bad as some would make it, a 6- to an 8-inch glass is doubtless the size which will be found the most constantly useful; larger apertures being frequently not only useless, but hurtful. Still, 4 or 3¾ inches are apertures by all means to be encouraged; and by object-glasses of these sizes, made, of course, by the *best* makers, views of the sun, moon, planets, and double stars, may be obtained, sufficiently striking to set many seriously to work as amateur observers, and with a prospect of securing good, useful results.

Observations should always be commenced with the lowest power, gradually increasing it until the limit of the aperture, or of the atmospheric condition at the time, is reached. The former may be taken as equal to the number of hundredths of inches which the diameter of the object-glass contains. Thus, a 3¾-inch object-glass, if really good, should bear a power of 375 on double stars where light is no object; the planets, the moon, &c., will be best observed with a much lower power.

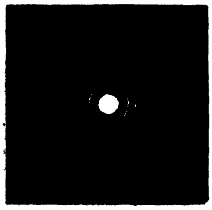

FIG. 7.—Appearance of diffraction rings round a star when the object-glass is properly adjusted.

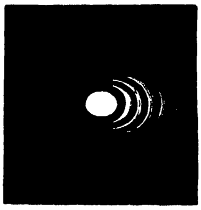

FIG. 8.—Appearance of same object when object-glass is out of adjustment.

Care should be taken that the object-glass is properly adjusted. And we may here repeat that this may be done by observing the image of a large star out of focus. If the light be not equally distributed over the image, or the diffraction rings are not circular, the screws of the cell should be carefully loosened, and that part of the cell towards which the rings are thrown very gently tapped with wood, to force it towards the eyepiece, or the same purpose may be effected by means of the set-screws always present on large telescopes, until perfectly equal illumination is arrived at. This, however, should only be done in extreme cases; it is here especially desirable that we should let well alone. In the case of mirrors, instructions for adjustment are generally given by the maker.

The convenient altitude at which Orion culminates in these latitudes renders it particularly eligible for observation; and during the first months of the year, our readers who would test their telescopes will do well not to lose the opportunity of trying the progressively difficult tests, both of illuminating and separating power, afforded by its various double and multiple systems, which are collected together in such a circumscribed region of the heavens that no extensive movement of their instruments—an important point in extreme cases—will be necessary.

Beginning with δ, the upper of the three stars which form the belt, the two components will be visible in almost any instrument which may be used for seeing them, being of the second and seventh magnitudes, and well separated. The companion to β, though of the same magnitude as that to δ, is much more difficult to observe, in consequence of its proximity to its bright primary, a first magnitude star. Quaint old Kitchener, in his work on telescopes, mentions that the companion to Rigel has been seen with an object-glass of 2¾-inch aperture; it should be seen, at all events, with a 3-inch. The bottom star in the belt is a capital test both of the dividing and space-penetrating power, as the two bright stars of the second and sixth magnitudes, of which the close double is composed, are exactly 2½″ apart, while there is a companion to one of these components of the twelfth magnitude about ¾″ distant. The small star below, which the late Admiral Smyth, in his charming book, "The Celestial Cycle," mentions as a test for his object-glass of 5·9 inches in diameter, is now plainly to be seen in a 3¾. The colours of this pair have been variously stated.

That either our modern opticians contrive to admit more light by means of a superior polish imparted to the surfaces of the object-glass, or that the stars themselves are becoming brighter, is again evidenced by the point of light, preceding one of the brightest stars in the system composing σ. This little twinkler is now always to be seen in a 3¾-inch, while the same authority we have before quoted—Admiral Smyth—speaks of it as being of very difficult vision in his instrument of much larger dimensions. In this very beautiful compound system there are no less than seven principal stars; and there are several other faint ones in the field. The upper very faint companion of λ is a delicate test for a 3¾-inch, which aperture, however, will readily divide the closer double of the principal stars which are about 5″ apart.

These objects, with the exception of ζ, have been given more to test the space-penetrating than the dividing power; the telescope's action on 52 Orionis will at once decide this latter quality. This star, just visible to the naked eye on a fine night, to the right of a line joining α and δ, is a very close double. The components of the sixth magnitude are separated by less than two seconds of arc, and the glass which shows a *good wide black division* between them, free from all stray light, the spurious disc being perfectly round, *and not too large*, is by no means to be despised.

Then, again, we have a capital test object in the great nebula to which reference has already been made.

The star to which we wish to call especial attention is situate (see Fig. 4) opposite the bottom of the "fauces," the name given to the indentation which gives rise to the appearance of the "fish's mouth." This object, which has been designated the "trapezium," from the figure formed by its principal components, consists, in fact, of six stars, the fifth and sixth (γ′ and α′) being excessively faint. Our previous remark, relative to the increased brightness of the stars, applies here with great force; for the fifth escaped the gaze of the elder Herschel, armed with his powerful instruments, and was not discovered till 1826, by Struve, who, in his turn, missed the sixth star, which, as well as the fifth, has been seen in modern achromatics of such small size as to make all comparison with the giant telescopes used by these astronomers ridiculous.

Sir John Herschel has rated γ′ and α′ of the twelfth and fourteenth magnitudes—the latter requires a high power to observe it, by reason of its proximity to α. Both these stars have been seen in an ordinary 5-foot achromatic, by Cooke, of 3¾-inches aperture, a fact speaking volumes for the perfection of surface and polish attained by our modern opticians.

Let us now try to form some idea of the perfection of the modern object-glass. We will take a telescope of eight inches aperture, and ten feet focal length. Suppose we observe a close double star, such as ξ Ursæ, then the images of these two stars will be brought to a focus side by side, as we have previously explained, and the distance by which they will be separated will be dependent on the focal length of the object-glass.

If we take a telescope ten feet long and look at two stars 1° apart, the angle will be 1°; and at ten feet off the distance between the two images will be something like $2\frac{1}{10}$ inches, and therefore, if the angle be a second, the lines will be the $\frac{1}{3600}$th part of that, or about $\frac{1}{1700}$th part of an inch apart, so that in order to be able to see the double star ξ Ursæ, which is a 1″ star, by means of an eight-inch object-glass, all the surfaces, the 50 square inches of surface, of both sides of the crown, and both sides of the flint glass, must be so absolutely true and accurate, that after the light is seized by the object-glass, we must have those two stars absolutely perfectly distinct at the distance of the seventeen hundredth part of an inch, and in order to see stars ½″ apart, their images must be distinct at one-half of this distance or at $\frac{1}{3400}$th part of an inch from each other.

J. NORMAN LOCKYER

BIOLOGICAL NOTES

CLASSIFICATION OF DECAPOD CRUSTACEANS.—In this well-defined group, the position of the anomurous forms (hermit-crabs, &c.) has often been the subject of doubt. The special adaptations of some genera for particular modes of life have caused them to be thrown together; and no doubt they agree in possessing neither the powerful abdomen of the lobsters, nor the very much aborted one of the crabs. Yet the anomurous forms include markedly contrasted groups. The family Hippidæ, with its lobster-like cephalothorax and firm abdomen, differs greatly in aspect from the hermit-crabs. *Hippa talpoida*, a small species found along the whole eastern coast of the United States, inhabits sandy beaches exposed to the waves, at a zone very near low-water mark. It has a smooth oval form, and short and stout thoracic legs (second, third, and fourth pairs), enabling it to burrow backwards in the sand with marvellous rapidity. In life the antennæ are peculiarly crossed, with the flagella curved round the mouth so that the setæ, with which they are densely covered, all project inwards, and the function of the antennæ appears to consist chiefly in the removal of all parasitic growths or foreign bodies from the anterior parts of the body. The appendages of the mouth are not adapted for prehension or mastication, and the alimentary canal is found loaded with fine sand. The thoracic appendages have neither external nor superior elements (exopodites, epipodites); while the office of protecting and cleaning the gills is discharged by the small limbs corresponding to the fifth pair of ambulatory legs in lobsters, which are curved upwards and hidden beneath the carapace. The development of this form has been recently carefully described by Mr. Sidney Smith, of Yale College, in the *Transactions* of the Connecticut Academy, vol. iii. p. 311. They pass through larval stages very analogous to the zoëa stages of crabs, only being destitute of a large dorsal spine; and they then assume a form like the brachyuran megalops, with large eyes, and powerful abdominal swimming legs. But in this condition they buried themselves in sand with great alacrity. Thus it is determined that the embryonic development of Hippa, as well as of Albunea, studied by Claus, agrees much more closely with that of crabs proper than with hermit crabs or lobsters; and this publication by Mr. Smith furnishes an important addition to the evidence favouring the view that the Anomura are a heterogeneous group made up of specialised families of Brachyura and Macrura.

THE AMERICAN BISON.—Mr. J. A. Allen's valuable "History of the American Bison," so sumptuously produced by the Geological Survey of Kentucky and the Harvard Museum of Zoology, has excited so much interest that to supply the demand for it Dr. Hayden has republished almost the whole of the text in the ninth annual report of his survey of the territories, and as a separate pamphlet of 150 pages, with considerable additions by the author. One of the most interesting of these consists in the publication of a letter from Mr. J. W. Cunningham, of Howard County, Nebraska, on the domestication of this species. It appears that the bison has been crossed with the ordinary milch cow, and that half- and quarter-breds are not uncommon, and the cows yield extremely rich milk. They prove to be both hardy and tame. The colour of the bison and the majority of the distinguishing characters disappear after repeated crossings. The lump of flesh covering the dorsal vertebræ also becomes diminished. The preservation of a pure domestic breed of the bison does not seem so easy. In some instances where buffaloes have been broken to the yoke they have proved strong and serviceable, but rather unmanageable at times. Unless the breed is maintained in some way artificially, the wild species will no doubt before very long become extinct.

PRODUCTS OF ASSIMILATION IN MUSACEÆ.—Herr Emil Godlewski has recently investigated whether in the case of Musaceæ the first assimilation-product is oil or starch, which latter is the first product in most plants. Sig. Briosi had recently maintained that oil was first produced. The question which had to be solved, therefore, was whether these plants, when decomposing carbonic acid under the influence of light, exhale a volume of oxygen greater than that of the carbonic acid decomposed. If oil is formed from the carbonic acid this must be the case. Measurements which Herr Godlewski made to this end with *Musa sapientium*, gave negative results; the oxygen exhaled was not of greater volume than the carbonic acid decomposed. Sig. Briosi had failed to discover starch in the grains of chlorophyll of the mesophyll-cells of the leaves; while Herr Godlewski was perfectly successful also in this direction, perceiving numerous granules of starch in leaves from young specimens of species of both *Musa* and *Strelitzia*, which had been collected in the evening after a hot day.

FERTILISATION IN THYME AND MARJORAM.—Under the title of "Das Variiren der Grösse gefärbten Blüthenhüllen, und seine Wirkung auf die Naturzüchtung der Blumen," Dr. Hermann Müller reprints from *Kosmos* a paper containing many of the facts which have appeared from time to time with his signature in these columns. The special point to which he calls attention is the occurrence in many species of Labiatæ—*Thymus serpyllum*, *Origanum vulgare*, &c.—of two distinct forms, one with larger hermaphrodite protandrous, the other with smaller female flowers. The second of these two forms can manifestly only be fertilised by the former, and will disappear where the conditions of life are unfavourable; while the propagation of the first form is in no way dependent on the other.

A FOSSIL FUNGUS.—One of the most interesting recent discoveries in palæophytology has recently been made by Mr. Worthington Smith, in the detection, in the coal-measures, of a fossil fungus nearly allied to that which produces the potato blight, and which he has named *Peronosporites antiquarius*. Fossil fungi were not previously altogether unknown. Some years ago Mr. Carruthers, the keeper of the botanical department at the British Museum, detected mycelial threads among the cells of a fossil fern (*Osmunda*) from the Lower Eocene strata of Herne Bay; and Mr. Darwin has stated that fungus threads in a fossil state in silicified wood were shown to him more than forty years ago by the late Mr. Robert Brown. Messrs. Hancock and Atthey have also described in the *Annals and Magazine of Natural History* (4th ser. vol. iv. 1869, p. 121, t. ix. x.), under the name of *Archagaricon*, what may be a fossil *Peronosporites* from the Cramlington black shale. The specimen examined by Mr. Worthington Smith (the fungoid nature of the organism having been first suggested by Mr. Carruthers), was seen within the vascular axis of a *Lepidodendron*, and is thus described by that gentleman:—It consists of a mass of mycelia and zoosporangia (or oogonia). Beginning with the mycelium, a close examination shows that it is furnished with numerous joints or septa. If, therefore, any reliance is to be placed upon the modern distinguishing characters of the now living species of the genera *Peronospora* and *Pythium*, as furnished by a septate or non-septate mycelium, the fossil parasite belongs to the former, and not to the latter genus, nor to any of the Saprolegnieæ. The oogonia do not agree with those of *Cystopus*. Within many of the fossil oogonia the differentiation of the protoplasm into zoospores is clearly seen; but if any doubt could exist as to the exact nature of this differentiation, then other oogonia (or zoosporangia) on the same slide show the contained zoospores with a clearness not to be exceeded by any living specimens of the present time. It is a very remarkable fact that the oogonium precisely resembles, in size and other characters, average oogonia of the present day, especially those belonging to *Peronospora infestans*. The contained zoospores are, moreover, the same in form and dimensions with those of *P. infestans* when measured to the ten-thousandth of an inch. The organisms are, in fact, apparently identical; and the average number of zoospores in each oogonium is also the same, viz., seven or eight. The aërial condition of the fungus has not yet been observed. Mr. Worthington Smith suggests, in conclusion, that we probably have, in *Peronosporites antiquarius*, one of the primordial plants from which both the great families of fungi and algæ may possibly have descended; but should not this primordial plant have led a non-parasitic life?—for if parasitical, then this fact points to some pre-existing plant.

THE LAWS OF DIGITAL REDUCTION.—Hitherto there has been little explanation of the curious variation in the number and relative size of the digits in the vertebrata. Mr. John A. Ryder (*American Naturalist*, October) suggests that the number of toes is least where the mechanical strains are greatest, and impacts most frequent and severe. He quotes several cases in which the hinder digits are reduced more than those of the fore feet, and shows that in all of them the body in jumping or running pitches mainly upon the hind limbs. He looks upon the outer toes of man as in process of undergoing reduction, being now weaker and shorter than in any of the higher apes. The chrysochloris among moles is an instance of special reduction in the anterior extremity, and here the mechanical strains are most frequent and severe. Among fossorial animals the claws and toes are usually best developed on the fore limbs. The retention by certain groups, of digits in a very equal state of development in manus or pes, or both, is attributed to the equal distribution of strains on all.

THE BIRDS OF GUADALOUPE ISLAND.—This interesting fauna is dealt with by Mr. Robert Ridgway in the *Bulletin* of the Nuttall Ornithological Club for July. It is strange that only eight forms from this island, situated about 220 miles south-west of San Diego, are satisfactorily known, and their affinities are almost entirely with those of western North America. They are recognised by Mr. Ridgway, however, as specifically distinct, differing from their nearest mainland allies in the (1) increased size of the bill and feet, (2) shorter wings and tail, and (3) darker colours.

THE DISTRIBUTION OF FRESHWATER FISHES.—Dr. D. S. Jordan, the well-known American ichthyologist, has contributed to the *American Naturalist* for October some of his conclusions derived from long study of the fishes of rivers flowing in different directions, and under the most widely-varied physical conditions. He finds that in the case of rivers flowing into the ocean, the character of the fishes of the upper waters bears little or no relation to the place of discharge. The higher or the older the watershed between two rivers, the fewer species are common to both. Certain species (not including species of general distribution) occur on opposite sides of even the highest watersheds. When the watershed between two rivers is a swampy district, the same species are found in the head waters of both, though the faunas of the lower courses may be distinct. There is often a great difference between the forms in the upper and lower waters of a river, owing to differences in physical conditions. Some species are strictly confined to one river basin; others are widely distributed. Usually the more southern rivers have the most peculiar and varied faunas. Species of the widest distribution often have breaks in their range which cannot be accounted for by any known facts. The characteristically American forms of freshwater fishes are, generally speaking, absent or rare in the waters of New England and of the Pacific slope. The larger the river-basin, the greater its variety of forms. Seventy species have been taken in the little White River at Indianopolis, representing forty-eight genera, twice as many as occur in all the rivers of New England. Other things being equal, a river whose course lies in a region of undisturbed stratified rocks, or of glacial drift, contains most genera and species. Certain forms appear generally distributed in a definite range, either without regard to the direction in which the rivers flow, or even bounded by parallels of latitude. In any river-basin the most abundant species (of small fishes) are usually (1) those peculiar to it, or (2) those of widest distribution.

EARWIGS (FORFICULIDÆ).—Linnæus seems to have known but two species of earwigs (*Forficula auriculata* and *minor*). Both were European, and had *Elytra dimidiata et Alæ tectæ*, and were placed among the beetles (Coleoptera). There are now about 250 species known which are found all over the world, and grouped in about thirty genera, of which the genus Forficula is by far the richest in species and the widest in its geographical distribution. Happily, too, it still retains the two first-named species, and it has also most justly given its name to the family. Entomologists will be glad to know that Mr. Samuel Scudder has just published a series of critical and historical notes on this family, in which he gives descriptions of all the known genera, and an alphabetical list with full synonyms of all the described species; this most valuable list will make the study of these interesting insects an easy one. It is published in Parts 3 and 4 of vol xviii. of the *Proceedings* of the Boston Society of Natural History.

HUNGARIAN SPIDERS.—The first part of a work on Hungarian Spiders by Assistant-Director Otto Hermann, of Buda Pest, has just reached us. It forms a handsome royal-quarto volume, with three plates, and is printed in double columns, one in Magyar, and the other, fortunately for us, in German. This volume forms part of the *Transactions* of the Royal Hungarian Natural History Society, which is really to be congratulated on the appearance of this and the next work that we will mention. The present volume gives a sketch of the literature belonging to spiders, and forms one of the most generally interesting portions of the work, for it is most carefully elaborated, being divided into the bibliography of the older and the newer times. It further treats of the life-history of spiders in general, and of the geographical distribution of those species to be met with in Hungary. The next volume will contain the spiders met with in Hungary proper.

HUNGARIAN ROTIFERS OR WHEEL-ANIMALCULES.—A memoir on Hungarian Rotifers by Dr. Bartsch Samu is also published under the auspices of the Royal Hungarian Natural History Society, but it is written exclusively in Magyar, if we may except a short appendix containing brief descriptions of the new species determined by the author, and therefore unfortunately we can do no more than call attention to it.

OUR ASTRONOMICAL COLUMN

THE SATELLITES.—The following table presents at one view the mean distances of the satellites from their primaries, expressed in equatorial semi-diameters of the latter, and founded upon the most reliable data hitherto available :—

	The Earth.	Mars.	Jupiter.	Saturn.	Uranus.	Neptune.
I.	60·27	2·72	5·70	2·98	7·71	14·55
II.	—	6·81	9·07	3·83	10·75	—
III.	—	—	14·46	4·75	17·63	—
IV.	—	—	25·44	6·08	23·57	—
V.	—	—	—	8·47	—	—
VI.	—	—	—	19·67	—	—
VII.	—	—	—	24·80	—	—
VIII.	—	—	—	57·28	—	—

It will be seen that the outer satellite of Saturn, Iapetus, is the only one revolving round its primary at a distance similar to that of our moon, with respect to the semi-diameter of the central body. The exterior satellites of Jupiter and Uranus are similarly placed in this respect, and as regards the former planet the reader will remember a suggestion of Sir John Herschel's, that a distant satellite, by which was intended one situate more nearly, as our moon or the Saturnian satellite Iapetus, might be "worth a search." At the end of the last century it was thought that if satellites of Mars existed they might be "distant many degrees from the principal planet," upon which idea the late Prof. D'Arrest argued that a search after a satellite situate many degrees from Mars would be an almost endless task; and further, that a satellite at a maximum digression of seventy minutes of arc would have a sidereal period greater than the synodical revolution of the primary. The same astronomer endeavoured to ascertain, at the opposition of 1864, to what magnitude stars were visible in the vicinity of Mars with the Copenhagen refractor, which has an aperture of about eleven English inches. He considered that a satellite as bright as the twelfth magnitude could hardly have escaped him, and that objects of a fainter class were only visible in such an instrument at distances of eight or ten minutes, and in the case of Mars opportunities of viewing a satellite in such position would occur comparatively seldom. Perhaps the more prevalent idea respecting possible satellites of Mars, prior to their actual discovery, was that they would be "very small and close to the planet." (Hind, in "Solar System," p. 78.)

TYCHO BRAHE'S STAR OF 1572.—It is to be hoped that the vicinity of the famous star in Cassiopeia, with which we are accustomed to associate Tycho Brahe's name, may continue to receive frequent attention, and in particular that the small star, which at present is so near to the most accurate position we are able to obtain of the star of 1572, may be assiduously watched and its brightness determined from time to time by comparison with its neighbours, and not merely by estimation of magnitude. It was Bessel who, as he states in a letter to Olbers, in 1824, first engaged Argelander to work up the position of the Nova Cassiopeiæ, with all possible precision. Forty years later Argelander revised his calculations with improved positions for the reference-stars, and obtained a result differing in no material degree from the earlier one. The small star alluded to is so near to Argelander's last position (differing only fifty seconds of arc), as to be within its possible limits of error; it is No. 129 of the catalogue of stars in the vicinity which was presented to the Copenhagen Academy in January, 1864, and an eleventh magnitude on Bessel's scale. It will be most readily identified by means of the star of the ninth magnitude, No. 300 of Oeltzen's Catalogue from Argelander's northern zones, the position of which for 1878·0 is in R.A. 0h. 17m. 32s., N.P.D. 26° 22′·6; the suspicious object follows Argelander's star 29·6s., and is south of it 10′ 4″. The place of Nova for 1878·0 is in R.A. 0h. 18m. 2·1s., N.P.D. 26° 31′ 43″.

THE AUSTRIAN COMET-MEDAL.—We have received from the Imperial Academy of Sciences at Vienna, the conditions upon which that body has resolved to renew, until further notice, the prizes for the discovery of telescopic comets, and which appear to be similar to those originally issued in June, 1872. The awarding of a prize, which will consist, according to the wish of the receiver, in a gold medal or its money value of twenty Austrian ducats, is connected with the following conditions: (1) Prizes will be awarded only for the first *eight* successful discoveries in each calendar-year, for comets that at the time of their discovery were telescopic, *i.e.* invisible to the naked eye, that had not been previously seen by any other observer, and which could not have been predicted, and it is important to observe that in the case of independent discoveries priority is to be decided by the epoch of the first position. (2) The discovery must be communicated to the Academy of Sciences immediately, by telegraph, where practicable, otherwise by the earliest mail, the Academy undertaking to make it known without delay to several observatories. (3) This first notice must necessarily contain the position and motion of the comet as accurately as they are known, with the place and time of discovery, and is to be supplemented at the next opportunity by later observations. (4) If the discovery should not have been verified by other observers, the prize will only be adjudged "when the observations of the discoverer are sufficient for determining the orbit." (5) The prizes will be awarded in the general sitting of the Academy held at the end of May in each year, and in cases where the first intimation of the discovery arrives between March 1 and May 31, the award will be decided in the general May session in the following year. (6) Application must be made for the prize to the Imperial Academy within three months after the first notice of discovery shall have reached it, later applications being rejected. Finally, the astronomers of the observatory of the University of Vienna are appointed judges, whether the conditions in (1), (3), and (4) have been fulfilled.

GEOLOGICAL WORK OF THE U.S. SURVEY UNDER PROF. HAYDEN DURING THE SUMMER OF 1877

THE necessity of a careful examination of the various geological formations in the field, and a review by a practical palæontologist of the various districts that have from year to year been surveyed by the different geologists of this and other surveys, has been long felt. Such a work, indeed, was imperatively necessary, before a consistent and comprehensive classification of the formations could be established. This duty was assigned to Dr. C. A. White, the palæontologist of this survey, and he took the field at the beginning of the past season and continued his labours until its close. The special duty with which he was charged was to pursue such lines of travel as would enable him to make critical examination of the geological formations in succession as they are exposed to view on both sides of the Rocky Mountain chain, and also on both sides of the Uinta chain; to collect and study the fossils of these formations in such detail as to settle, as far as possible, the questions of the natural and proper vertical limits of the formations, their geographical range, their correlation with each other, and to define the palæontological characteristics of each.

He has pursued his researches with such success during the past season as to demonstrate the necessity of continuing this class of investigations by various lines of travel across what is generally known as the great Rocky Mountain region, especially those portions of it that have been surveyed, as well as those in which surveys are in progress.

Among other important results, he has shown the identity of the lignitic series of strata east of the Rocky Mountains, in Colorado, with the Fort Union group of the Upper Missouri River, and also its identity with the great Laramic group of the Green River Basin and other portions of the region west of the Rocky Mountains. He also finds the planes of demarcation between any of the mesozoic and cenozoic groups, from the Dakota to the Bridger, inclusive, to be either very obscure or indefinable; showing that whatever catastrophal or secular changes took place elsewhere during all that time, sedimentation was probably continuous in what is now that part of the continent, from the earliest to the latest of the epochs just named.

The general course of travel pursued by Dr. White during the season was as follows, not including the numerous detours, meanderings, and side trips, which the work necessitated. Outfitting at Cheyenne, he journeyed southward, traversing in various directions a portion of the great plain which lies immediately adjacent to the eastern base of the Rocky Mountains in Colorado. The most easterly point thus reached was some sixty miles east of the base of the mountains, and the most southerly point, about twenty-five miles south of Denver. Returning to Denver to renew his outfit, he crossed the Rocky Mountains by way of Boulder Pass, through Middle Park. After making certain comparative examinations of the mesozoic and cenozoic formations in Middle Park, he proceeded westward to the head-waters of Yampa River, following that stream down to the western foothills of the Park Range of mountains. Here, resuming his comparative examination of the mesozoic and cenozoic strata, he passed down the Valley of the Yampa as far as Yampa Mountain, one of those peculiar and remarkable upthrusts of palæozoic rocks through mesozoic strata. In all this area, as well as that between the Yampa and White Rivers, the Laramic group reaches a very great and characteristic development; and it received careful investigation, yielding some of the most important results of the season's work. Crossing the ground between the two rivers named, to White River Indian Agency; thence down White River Valley about 100 miles, thence to Green River, crossing it at the southern base of the Uinta Mountains, making many detours on the way, he reviewed the geology of the region which he had surveyed during the previous season. This review brought out not only the important palæontological facts before referred to but it also added materially to the elucidation of the geological structure of the region which lies between the eastern end of the Uinta mountain range on the west, and the Park range on the east.

Beyond Green River he pursued his travels westward, studying the mesozoic and cenozoic strata that flank the Uinta range upon its south side, and making comparisons of both their lithological and palæontological characteristics.

In this way he traversed the whole length of the Uinta range, crossing at its junction with the Wasatch range over into the valley of Great Salt Lake. Re-crossing the Wasatch to the north side of the Uinta range, he continued his examinations of the cretaceous and tertiary strata into and entirely across the Great Green River basin, leaving the field at the close of the season at Rawlin's station on the Union Pacific Railroad.

A general statement of the results of the season's work has been given in a previous paragraph, but the following additional summary will make the statement somewhat clearer, being made after the route of the season's travel has been indicated. The formations of later mesozoic and earlier cenozoic ages, especially those to which Dr. White, in former publications, has applied the provisional designation of "post-cretaceous," have received particular attention. The extensive explorations of Dr. Hayden in former years, and the palæontological investigations of the late Mr. Meek, pointed strongly to the equivalency of the Fort Union beds of the Upper Missouri River with the lignitic formation as it exists along the base of the Rocky Mountains in Colorado; and also to the equivalency of the latter, with the Bitter Creek series west of the Rocky Mountains. The investigations of the year have fully confirmed these views by the discovery not merely of one or two doubtful species common to the strata of each of these regions, but by an identical molluscan fauna ranging through the whole series, in each of the regions named. This shows that the strata just referred to all belong to one well marked period of geological time; to the strata of which Mr. King has applied the name of "Laramic group" (Point of Rocks, Group of Powell). His investigations also show that the strata which in former reports by himself and Prof. Powell, have been referred to the base of the Wasatch group, also belong to the Laramic group, and not to the Wasatch. He has reached this later conclusion not merely because there is a similarity of type in the fossils obtained from the various strata of the Laramic group with those that were before in question; but by the specific identity of many fossils that range from the base of the Laramic group up, into, and through the strata that were formerly referred to the base of the Wasatch. Furthermore some of these species are found in the Laramic strata on both sides of the Rocky Mountains. Thus the vertical range of some of these species is no less than three thousand feet and their present known geographical range more than a thousand miles.

Besides the recognition of the unity of the widely distributed members of the formation of this great geological period, bounded by those of undoubted cretaceous age below, and those of equally undoubted tertiary age above; his further observations have left comparatively little doubt that the "lake beds" of Dr. Hayden, as seen in Middle Park, the "Brown's Park group" of Prof. Powell, and the "Uinta group" of Mr. King, all belong to one and the same epoch, later than, and distinctly separate from, the Bridger groups. In that portion of the region which lies adjacent to the southern base of the Uinta mountain range, and which is traversed by Lake Fork and the Du Chesne River, not only the Uinta group, but both the Green River and Bridger groups also, are well developed, each possessing all its peculiar and usual characteristics, as seen at the typical localities in the great Green River Basin, north of the Uinta Mountains. This, added to the known existence of Bridger strata in White River Valley, and the extensive area occupied by the Green River group between White and Grand Rivers, has added very largely to our knowledge of the southward extension of those formations.

In all the comparative examinations of the formations or groups of strata that have just been indicated he has paid special attention to their boundaries or planes of demarcation, crossing and recrossing them wherever opportunity offered, noting carefully every change of both lithological and palæontological characters. While he has been able to recognise with satisfactory clearness the three principal groups of cretaceous strata, namely, the Dakota, Colorado, and Fox Hills, on both sides of the Rocky and Uinta Mountains respectively, they evidently constitute an unbroken series so far as their origin by continuous sedimentation is concerned. While each of the groups possesses its own peculiar palæontological characteristics, it is also true that certain species pass beyond the recognised boundaries of each within the series.

The stratigraphical plane of demarcation between the Fox Hills, the uppermost of the undoubted cretaceous groups, and the Laramic group, the so-called post-cretace[illegible], is equally obscure; but the two groups are palæontologically very distinct, inasmuch as the former is of marine origin, while the latter, so far as is now known, contains only brackish-water and fresh-water invertebrate forms. He reports a similar obscurity or absence of a stratigraphical plane of demarcation between the Laramic and Wasatch groups, although it is there that the final change from brackish to entirely fresh waters took place over that great region. Furthermore, he finds that while the three principal groups of the fresh-water tertiary series, west of the Rocky Mountains, namely, the Wasatch, Green River, and Bridger groups, have each peculiar characteristics, and are recognisable with satisfactory distinctness as general divisions, they really constitute a continuous series of strata, not separated by sharply-defined planes of demarcation, either stratigraphical or palæontological.

During the progress of the field work, as above indicated, large and very valuable collections of fossils have been made, all of which will constitute standards of reference in the future progress of the work, and quite a large number of the species are new to science. These are now being investigated, and will be published in the usual palæontological reports of the survey.

NOTES

At the moment of going to press we have received the report of the *Inflexible* Committee. The impression a first glance over it gives is that the *Inflexible* is a passable ship, but that the Committee strongly urge the Admiralty not to proceed with any more like it, which practically puts an end, we presume, to the *Ajax* and *Agamemnon*, in their present form, as well as to the fourth ship which the Admiralty proposed to build. It is proper, however, to state that a closer perusal of the report shows the *Inflexible* herself to be open to the gravest objections in several respects, and that the Committee recommend considerable modifications in her. In our next number we shall fully review the report.

We have received several letters from India, showing that great interest is being taken in that country with reference to the best methods of determining the amount and variation of solar radiation. We may state that both Prof. Stewart and Mr. Lockyer have recently devised instruments to secure these data. The latter proposes to utilise Capt. Abney's method of obtaining photographs of the red end of the spectrum, so that variations in thermal and chemical intensity may both be recorded automatically.

Sir William Thomson has been elected a Foreign Associate of the Paris Academy of Sciences, to fill the place vacated by the death of von Baer.

Prof. Sir Wyville Thomson has been created a Knight of the Royal Order of the Polar Star by the King of Sweden.

M. Tempel is to continue henceforth the publication of Donati's *Bollettino* of the Arcetri Observatory, of which only one number had been issued when Mr. Donati died.

Gen. Nansouty, Director of the Observatory situated on the top of the Pic du Midi has been nominated "Officier de l'Université" by M. Faye, the new Minister of Public Instruction. The General, as our readers know, spends his winters on that precipitous mountain for meteorological observations. We are glad to register such an acknowledgment of his devotion to science.

Dr. Burdon-Sanderson gives notice that the first of his annual course of lectures on comparative pathology will be delivered at the University of London, Burlington Gardens, on Saturday, December 15, at half-past five o'clock. The subject of the lecture will be, "The Infective Processes of Disease." The succeeding lectures will be on the Monday, Wednesday, and Friday of the following week, at the same hour, for which days "The Nature and Causes of Septic Infection," "The Germ Theory," and "The Theory of Contagium Vivum," are among the topics to be discussed.

The German postal department has issued a complete series of regulations for the use of the telephone in the various offices where it has been established. In § 15 we notice the rule that the speaker shall pronounce each syllable slowly and separately, and make a pause at the end of every six words to give time for the receipt of the message. The receiver repeats the whole message at the end at an ordinary rate of delivery. Proper names and foreign messages are spelled. The Postmaster-General, Dr. Stephan, who wages an unmerciful war in his department against all foreign words where a German equivalent is possible, has christened the new invention as the *Fernsprecher* (far-speaker), and excluded entirely the Greek *telephone* from his regulations.

In consequence of the large numbers who were unable to obtain admission to the recent lecture at the Society of Arts on the "Telephone," Prof. Bell, at the special request of the Council of the Society, has consented to repeat his lecture on Wednesday, the 19th inst. As there is certain to be a large attendance, it is suggested that those members who heard the first lecture, should refrain from exercising their privilege of being present on the second occasion.

Prof. Kekulé, of Bonn, the originator of the present benzene theory has been nominated for president of the German Chemical Society for the coming year. The policy which the society adopted at its last annual election of choosing its chief officer from among the leading German chemists at a distance from the headquarters of the society, seems to meet general favour, and Prof. Wohler, the Nestor of organic chemistry, will certainly be ably succeeded by Prof. Kekulé, whose classical researches and theoretical deductions form the basis of the present atomistic theory. The German Chemical Society would do well to copy one of the customs of its sister society in London, viz., to require an inaugural address from its newly-elected presidents. We notice that the library of the society will be enriched by the bequest of the extensive chemical library of the late Prof. Oppenheim, an accession which will double the present number of volumes.

Dr. Vohl, of Cologne, has adopted an ingenious method of determining the impurities in the Rhine, which consists in analysing the boiler incrustations of the river steamers, as well as the concentrated residues remaining in the boilers after passing over a certain distance. By this means he has detected the presence of a large amount of arsenious acid in the river water—resulting chiefly from the aniline and dyeing establishments—as well as other poisonous substances. An unusually high percentage of phosphoric acid showed that the sea was daily absorbing vast quantities of the most valuable fertilising material from the soil of Germany.

The Scientific Congress of France will meet at Nice from January 10 to 20, 1878. The locality is likely to attract many visitors at such a cold period of the year.

Another sitting of the enlarged Council of the Observatory of Paris was held on December 9. The councillors passed a resolution for an increase of the salary of the astronomers and auxiliary astronomers, the maximum pay of the former to be 10,000 francs instead of 8,000, and of the second 7,000 instead of 6,000. They propose to the Government to place the appointment of the director of the establishment partly in the hands of the Academy of Sciences and partly in the hands of the Council, the Minister to have only the privilege to choose between both presentations. It should be remembered that under the former organisation the appointment of the director was in the hands of the Bureau des Longitudes, which had to designate yearly their member to preside over the observations. Arago and his illustrious predecessor held their office by a yearly tenure, renewed up to the time of their death. It was only Leverrier who was appointed by the Government; under the old monarchy the director was appointed by the king. A proposal was made for suppressing the general assembly of astronomers, which was established by M. Leverrier, and is to be held at Easter at the Ministry of Public Instruction. The proposal was out-voted. At the next sitting the long-discussed organisation of meteorology will be introduced; the existing order of things continues to enjoy the support of the majority.

A TELEGRAM from Alexandria states that Capt. Burton has started from Suez for Moilah on a second expedition to Midia, accompanied by many Europeans and a large number of native workmen and troops. A dépôt will be formed at Moilah in the Gulf of Akaba, and the expedition will extend to the second range of mountains hitherto unexplored. Capt. Burton expects to discover a rich mineral country between the two ranges of mountains. He will be absent four months.

THE Montsouris Park, in the centre of which the Montsouris Observatory has been erected, is almost ready for public use. Admittance to the observatory grounds will be procured on application to the secretary, for the purpose of inspecting the instruments and the working of the meteorological observations.

IN Würtemberg a remarkable property of ripe grapes has been recently discovered, which the agricultural authorities have now published, so that all proprietors of vineyards may derive benefit from being acquainted with it. It appears that if ripe grapes, which have become frost-bitten, are kept for a little time in some dry place, they entirely lose the bad effects caused by the frost.

IN the *Bulletin* of the French Geographical Society for October are some interesting notes from the Abbé Desgodins, on Tibet. The Abbé gives some information concerning the Brahmapootra, which he obtained from an old lama, whom he believes to be thoroughly trustworthy. This lama has travelled much, and visited nearly the whole of Tibet. His information goes to prove the identity of the Yar-tsiou-tsang-po with the Brahmapootra. He has followed the great river from its source in or near the lakes of Tso-ma-pang in the west of the province of Ngaré, the most western of Tibet, and in making his pilgrimages he has reached the frontiers of the savage tribe of the Lhopa. The lama states that some days to the east of Lassa the river turns towards the south, making a great bend, and traverses the well-peopled and rich district of Hia-yul, just to the north of the Lhopa. Passing through the latter district, it flows among steep and rugged rocks, and after a certain distance forms a great waterfall. This fall of the Yar-kiou-tsang-po, M. Desgodins has no doubt, is identical with the fall of Brama-Khoond, well known to the Assamese. The lama affirmed that the river did not reach so far as the Nahengs (Mishmis), but that it disappeared more to the west, among the Lhopa. The lama gave the Abbé, besides, much information concerning the people and the districts through which the river passes. The *Bulletin* contains, besides, a learned article by M. E. Cortambert on some of the geographical monuments of the middle ages in the National Library, dwelling at considerable length on the well known Mappemonde of Beatus, a beautiful facsimile of which is given.

THE Italian Geographical Society has received letters from Aden dated November 25, which confirm the arrival of the second Italian (Martini-Cecchi) expedition at Faré. There is no news at all about the supposed defeat of King Menelik of Schoa in connection with which the death of the Marquis Antinori was reported. It seems, however, that King Kassa gained a victory over a Prince Menelik (son of the late King Theodor), who had rebelled in Kassa's camp. The resemblance of names explains the misunderstanding and deprives of any foundation the news about the misfortune said to have happened to the members of the first Italian (Antinori) expedition.

THE French Acclimatisation Society held its anniversary meeting on December 7 last, under the presidency of M. Quatrefages. The Society lost recently M. Drouyn de Lhuys, one of its founders, a former minister of the empire, well known in France as well as abroad.

IN this month's *Geographical Magazine* Mr. C. R. Markham continues his valuable papers on Irrigation in Southern India, and Mr. G. J. Morrison concludes his interesting description of the island of Formosa. In criticising Mr. Trelawney Saunders on the question of "Water-partings *versus* Ranges," Mr. R. B. Shaw appears to have misconceived Mr. Saunders' statements; Mr. Saunders' knowledge is too extensive and accurate to allow him to maintain the identity of the two terms. Sir George Nares contributes an important article on the Greenland Foehn, recently noticed in NATURE.

WE are glad to learn from the *Geographical Magazine* that the Dutch are making active preparations to resume Arctic exploration, to which they have been able to do little since the days of the brave but unfortunate Barentz, and nothing at all, we believe, during the last century. A new schooner is to be built to be sent out in May next year to make a summer cruise in the Spitzbergen and Barentz Seas.

THE hygrometer devised by M. Alluard, described in NATURE, vol. xvii. p. 14, was constructed by M. L. Golaz, of 24, Rue des Fossés St. Jacques, Paris, who contributed some beautifully-constructed apparatus to the recent Loan Collection at South Kensington.

DR. SCHLIEMANN, assisted by Mr. Streatfield, of the Science and Art Department, is busy arranging his Trojan treasures in the South Kensington Museum. Although a large space has been assigned for their reception, it will take considerable ingenuity to get all the interesting articles satisfactorily arranged.

M. DAHLANDER communicates to the Swedish Academy of Sciences the results of his observations on the comparative rapidity with which heated solid bodies are cooled by immersion in various liquids. If the cooling power of water be taken as unity, that of alcohol is 0·58, of mercury 2·07, of a concentrated solution of salt, 1·5, and of a concentrated solution of sulphate of copper, 1·03. The rapidity of the cooling increases with the increased temperature of the liquid.

THE twenty-first annual report of the committee of the Free Public Libraries and Museums of Sheffield, speaks favourably of the progress of these institutions. We are glad to see that the number of scientific works sought for both in the lending and consulting libraries bears a fair proportion to the number in other departments.

ACCORDING to the published reports of the Koenigsberg Board of Trade, the total production of amber in the province of Prussia amounted to 135 tons during the year 1876, of which eighty-five tons were furnished by one mine alone, viz., the mine of Palmnicken. This production considerably exceeded that of the previous year. The amber was exported principally to Austria, France, Russia, America, China, and Japan, while the export to India, Persia, and Australia does not pay the producers, and is therefore extremely limited. The number of workmen in the province who are employed in the production of amber amounts to nearly 1,400.

NOW that the struggle in the East seems to be reaching its crisis, the fine, large, clear map of the Bosphorus and the

Dardanelles, just published by Mr. Stanford, will be extremely useful to those who desire to follow, with intelligence, further movements, military or diplomatic.

Mr. Heighway's handbook of "Practical Portrait Photography" (London, Piper and Carter), has reached a second edition, into which some improvements have been introduced.

The death is announced of Mr. John G. Anthony, who for some years has had charge of the conchological department of the Cambridge Museum. He was one of the party accompanying Prof. Agassiz in his celebrated scientific expedition to Brazil.

The number of French communes receiving the daily warnings of the international service for agricultural purposes is increasing daily; the death of Leverrier has not destroyed that extraordinary movement. It is said the twenty districts into which Paris has been divided, will very soon have the daily warnings posted at each of their respective mairies. According to a saying attributed to M. Dumas, ' The existing meteorology had had it own plebiscitum."

Prof. J. Plateau, of Ghent, has reprinted (from the *Proceedings* of the French Association for the Advancement of Science, 1876) a paper on the question, Is the instinct of insects deceived by artificial flowers? As far as the series of experiments performed by him—rather few in number, but apparently carried out with great care—can be relied on, although insects may be attracted from a distance by the bright colours of artificial flowers, they are never tempted by the resemblance to alight on them in the hope of obtaining food from them. He concludes, therefore, that insects make use of some other organ than that of sight in the selection of the flowers which they visit.

Prof. E. Morren, of Liége, has issued the fifth annual edition of his "Correspondance Botanique," which contains a complete list of botanical gardens and museums, and the occupants of botanical chairs throughout the world. Even adding a number of "unattached" English botanists whose names are given, it is instructive to compare the number engaged in botanical research in Great Britain with that in France or Germany, or even in Italy or Russia.

A brief report of the third annual conference of the Cryptogamic Society of Scotland, held at Dunkeld in October last, has been published, from which it is evident the meeting was successful. The first fasciculus of the "Fungi Scotici Exsiccati" will be published in January. Dr. Buchanan White, Perth, will receive orders; no subscribers names can be received after the 20th inst.

We have received Part 2, 1876-77, of the *Transactions* of the Cumberland Association or Literature and Science, which contains a number of scientific papers of considerable value. Among these are six original papers communicated to the societies connected with the Association during the session, and selected by the Council for publication. Two of these will interest the scientific reader: "Jonathan Otley, the Geologist and Guide," by Mr. Clifton Ward, and "Notes on the Migratory Birds of the English Lake District," by Mr. John Birkett.

The seventh annual report of the Leeds Naturalists' Club and Scientific Association speaks in the most favourable terms of the continued progress of that society.

In the *Monatsbericht* of the Prussian Academy of Sciences for July, which has just appeared, we notice papers by H. Anvers, "On the Results of the Transit Observations with Bradley's Quadrant;" by H. Websky, "On the Horn-Mercury from el Doctor in Mexico;" by Prof. du Bois Reymond, Prof. Peters, and Prof. Möbius, "On the Amphibious Collections made by Dr. Sachs during his late trip to Venezuela."

In the *Atti della Reale Academia dei Lincei* at Rome, some interesting investigations are described, which were made by Messrs. A. and G. De Negri at the Chemical Laboratory of the Genoa University, on the purple dies of antiquity. The authors have thoroughly investigated the subject; after an elaborate account and an enumeration of the various historical data with regard to the molluscs from which the ancients obtained their purple colours, they enter into a discussion of the chemical and optical properties of these substances, the methods of dyeing with them, the adulterations found in them, and various other details concerning them. We must refer our readers to the original treatise for further particulars, as our space will not permit us to enter into them. The paper is accompanied by a number of plates, giving the spectra of the colours obtained from species of the genera *Applysia* and *Murex*. The same volume of this publication contains an excellent account, by Signor C. Bagnis, of the fungi species *Puccinia*, illustrated by no less than eleven well-drawn plates.

The Piscicultural Institution of Schwerin has recently made some important experiments with a view to ascertain whether the artificial culture of river Crawfish (*Astacus fluviatilis*) is possible on a large scale. The experiments were entirely successful. In the spring of last year some 700 crawfish with ova were placed into two circular ponds of only six feet diameter, and for each animal a separate hole had been constructed. At the end of November the ponds were drained in order to separate the young crawfish from the old ones. It appeared that of the latter only three or four were crawling about at the bottom of the pond while all the others had occupied their respective dwellings. The young were of the size of a bee and extremely lively; they were taken out of the ponds and already on the following day could be fed artificially with carrots and meat. Many a land or garden proprietor could thus make crawfish-culture a lucrative pastime at very little cost, particularly since the consumption of these crustaceans increases largely every year.

The last number of the *Zeitschrift für Ethnologie* contains a most valuable and elaborate review of the entire ethnological and anthropological literature of 1876, prepared by Prof. W. Koner. Over 1,000 pamphlets, periodicals, and books are referred to, and as few subjects are handled in a greater variety of languages than those in question, the labour of compiling such a report can easily be imagined.

We have received the third (final) part of Herr Axel Blytt's elaborate Flora of Norway, which is published by order of the Royal Norwegian Society of Sciences, and bears the title, "Norges Flora; eller Beskrivelser af de i Norge vildtvoxende Karplanter" ("Flora of Norway; or, Description of the Wild Plants in Norway.")

A correspondent asks where he can find a description of the mode of drying sections of trees. He has a transverse section, three inches thick, of an elm tree, and he wants to dry it so that it may be cut in veneer when ready.

The additions to the Zoological Society's Gardens during the past week include a Diana Monkey (*Cercopithecus diana*) from West Africa, presented by Mr. Walter Mayhew; a Rhesus Monkey (*Macacus erythræus*) from India, presented by Mr. R. S. Cox; two White Storks (*Ciconia alba*), a Common Heron (*Ardea cinerea*), a Greater Black-backed Gull (*Larus marinus*), European, presented by Mr. C. Clifton; a Hobby (*Hypotriorchis subbuteo*), captured at sea, presented by Mr. W. Kenney; two Lesser Sulphur-crested Cockatoos (*Cacatua sulphurea*) from the Moluccas, presented by Mrs. Roberts; seven Gelada Baboons (*Cynocephalus gelada*) from Abyssinia, four Barbary Turtle-Doves (*Turtur risorius*) from North Africa, deposited; two Schlegel's Doves (*Chalcopelia puella*) from West Africa, purchased.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIDGE.—The examination for open scholarships at Christ's College will be held on Tuesday, April 9. Candidates in natural science will be required to show a satisfactory knowledge of elementary chemistry, both theoretical and practical. Candidates are required to send in their names to one of the tutors of the college before April 2. Further information can be obtained on written application to Mr. John Peile, or the Rev. J. W. Cartmell, Christ's College.

SCIENCE AND ART DEPARTMENT.—The list has been published by the Science and Art Department of the successful candidates in honours at the examination of science schools and classes, May, 1877. We give the names of the two first in the first class of each subject:—Subject I. Practical, Plane, and Solid Geometry—John R. Smith, age 32, clerk; William J. Last, age 19, engineer. Subject II. Machine Construction and Drawing—Robert A. Sloan, age 22. engineer; William Sisson, age 24, engineer. Subject III. Building Construction—Crichton Walker, age 34, carpenter; Robert Henry, age 22, draughtsman. Subject IV. Naval Architecture—Frederick B. Ollis, age 18, shipwright's apprentice; George A. Agnew, age 23, shipwright's apprentice. Subject V. Pure Mathematics, Stages One, Two, and Three—George J. T. Harker, age 18, student; Arthur W. Ward, age 18, cotton broker. Stages Four and Five—Frederick W. Watkin, age 18, pupil; Arthur E. Holme, age 18, engineer. Subject VI. Theoretical Mechanics—William Sisson, age 24, engineer; William Martin, age 22, engineer. Subject VII. Applied Mechanics—Frank W. Dick, age 23, engineer; Fred Ogden, age 18, engineer, William J. Last, age 19, engineer, Robert A. Sloan, age 22, engineer, Robert Greenhalgh, age 22, engineer—eq. Subject VIII. Acoustics, Light, and Heat—Frederick E. Boughton, age 20, draught man; James Greer, age 31, Inland Revenue officer. Subject IX. Magnetism and Electricity—Robert A. Sloan, age 22, engineer, Frederick E. Boughton, age 20, draughtsman—eq.; William J. Last, 19, engineer. Subject X. Inorganic Chemistry—Charles N. Luxmore, age 19, chemist's assistant; Sidney E. Meates, age 17, chemical student. Subject XI. Organic Chemistry—Charles M. Luxmore, age 19, chemist's assistant. Subject XX. Navigation—George Goodwin, age 14, engineer's apprentice; William Allingham, age 26, clerk. Subject XXII. Steam—Robert A. Sloan, age 22, engineer, William Sisson, age 24, engineer—eq.; Alfred Cliff, age 22, engineer, Jerdan Nichols, age 21, engineer—eq. Subject XXIII. Physical Geography—John S. Harper, age 19, student in training; John Sharkey, age 29, schoolmaster. Subject XXIII. Physiography—George A. Freeman, age 26, schoolmaster; John A. Lakin, age 21, teacher, Fredk. J. Richardson, age 16, teacher—eq. Subject XXIV. Principles of Agriculture—Edward S. Chesney, age 21, student; William E. Akroyd, age 20, student. There have been no first class successes in Geology, Mineralogy, Animal Physiology, Elementary Botany, General Biology, Principles of Mining, Metallurgy, and Nautical Astronomy.

BRISTOL.—The annual meeting of the governors of University College was held on Friday last, when a report, on the whole satisfactory, was presented. The number of students has somewhat decreased, as indeed might have been expected, but there seems every reason to believe that the college has taken its place as an important centre of education in the west of England. The funds of the college, though considerable in amount, are yet not sufficient to keep it going with complete efficiency, and we hope the appeal made by the governors will be satisfactorily responded to. It is proposed to make the college a local centre for the examinations of the University of London.

PESTH.—A commission has recently been appointed by the various faculties, to make fitting preparations for the celebration of the first centennial of the opening of the university, which was performed by Maria Theresa in 1780. The university is wealthy, possessing property to the amount of 6,000,000 florins, and a library of 120,000 volumes, and forms the real centre of Hungarian intellectual life. The other two Hungarian universities, Klausenberg and Agram, were founded respectively in 1872 and 1874. At present the instructors number 150 and the students 2,630.

WÜRZBURG.—Prof. Sachs has declined the call to the vacant chair of botany at the Berlin University, and the authorities are still seeking a successor for the late Prof. Braun.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, December 6.—Points of resemblance between the suprarenal bodies of the horse and dog, and certain occasional structures in the ovary, by Charles Creighton, M.B., Demonstrator of Anatomy, Cambridge University. Communicated by Prof. Humphry, F.R.S.

On the tides at Malta, by Sir G. B. Airy, K.C.B., Astronomer-Royal.

Observations on hermetically-sealed flasks opened on the Alps, in a letter to Prof. Huxley, Sec. R S., by Prof. Tyndall, LL.D., F.R.S. Though the author believes the question of "Spontaneous Generation" is practically set at rest for the scientific world, he has been making some experiments on *Bacteria*.

He took with him this year to the Alps sixty hermetically-sealed flasks, containing infusions of beef, mutton, turnip, and cucumber, which had been boiled for five minutes and sealed during ebullition. These were kept for six weeks, when some were opened in a hay-loft and others on the edge of a precipice.

The two groups of flasks were then placed in the author's kitchen, where the temperature varied from about 65° to 90° Fahr. The result was that twenty-one of twenty-three flasks opened in the hay-loft were filled with organism; two of them remained clear. All the flasks opened on the edge of the precipice remained as clear as distilled water. Not one of them gave way.

Chemical Society, December 6.—The President in the chair.—The following papers were read:—On gallium, by W. Odling. The properties of the metal, its chloride, and sulphate, and their reactions, were given and specimens exhibited.—On nitrification, a report of experiments conducted in the Rothamsted Laboratory, by R. Warrington. Schloesing and Muntz have shown that nitrification is due to the action of an organised ferment whose action is suspended by chloroform. The author has completely confirmed the above statement, and has proved that carbolic acid and bisulphide of carbon also stop the action of the ferment, and moreover that darkness is essential for the process. The author has succeeded in converting a dilute solution of ammonium chloride into a nitrate by seeding it with some earth from a fairy ring and keeping it in the dark for three months.—On potable waters, by E. J. Mills, D.Sc. The author investigates the minute errors incidental to the process of Frankland and Armstrong with great care, suggests a new form of evaporator, and arrives at three natural constants or ratios of organic carbon to organic nitrogen in potable waters.—On some derivatives of allylacetone, by J. R. Crow. By the action of sodium, a secondary alcohol homologous with allyl alcohol was prepared; its acetate and dibromide were also investigated.—On a fourth method for estimating bismuth volumetrically, by M. M. P. Muir. The bismuth is precipitated as oxalate, the latter on boiling is converted into a basic oxalate, the precipitate is well washed, dissolved in hydrochloric acid, and the solution titrated with permanganate.—On the gas of the Grotto del Cane, by T. G. Young. This gas contains 61–71 per cent. of carbonic acid, the residual air having the composition oxygen, 20·25, nitrogen, 79·75.—Note on tetrabromide of tin, by T. Carnelly, D.Sc., and L. T. O'Shea. This body was obtained as a colourless liquid, solidifying to a mass of colourless crystals,—melts at 30° C., boils at 201°.

Meteorological Society, November 21.—Mr. H. S. Eaton, M.A., president, in the chair.—The following gentlemen were elected Fellows of the Society, viz.:—E. D. Archibald, B.A., R. W. P. Birch, Capt. W. F. Caborne, H. Clarke, L.R.C.P., Cohen de Lissa, F.S.S., R. Gordon, J. Hunter, jun., J. J. Lake, Rev. E. A. D. O'Gara, O.S.B., R. Pennington, LL.B., E. E. Prichard, and Rev. S. J. W. Sanders.—The following papers were read:—On the general character and principal sources of variation in the weather at any part of a cyclone or anti-cyclone, by the Hon. Ralph Abercromby, F.M.S. In a cyclone the broadest feature of the weather, as seen on a synoptic chart, is an area of rain about the centre surrounded by a ring of cloud, beyond which the sky is clear. The precise form and position of these areas vary with the type of pressure distribution, with the intensity of the cyclone, and with the rate of its progress; they are also influenced by local, diurnal, and seasonal variations, the general sphere of each of which is indicated. By recording the appearance to a single observer of any part of a cyclone as it passes over him, it is discovered that the area of rain and cloud-ring may be divided into two portions—the front and the rear—differing in physical appearance and general character of the weather by a line drawn through the centre, in front of which the barometer is falling and in rear of which it is rising. Details are given and it is shown that this character remains constant whatever changes the variations above mentioned may effect. In anti-cyclones synoptic charts show great irregularity in the positions of cloud, &c., owing to local, diurnal, and other variations, but to a single observer, who considers the surroundings and physical appearance, a certain general character can be discovered in every part. A marked contrast is shown to exist between the diurnal variation of the weather in a cyclone or anti-cyclone, and a probable connection is pointed out between the diurnal variation of the weather and the diurnal variation of the barometer.—On a remarkable barometric oscillation on January 30, 1876, by Robert H. Scott, F.R.S. At 8 A.M. a remarkable dip appeared in the barometric curve for Armagh. The total amount of reduction of pressure was ·097 inch in 25 minutes and for a portion of the time, from 8·5 to 8·10, the fall was ·058 inch, being at the rate of ·697 inch per hour. On looking to the other barograms, it was found that while a very similar oscillation of slightly greater amplitude, ·102 inch, appeared at Aberdeen at noon, almost exactly four hours subsequent to the occurrence at Armagh, hardly a trace of disturbance could be detected in the barogram for Glasgow, and yet the last-named observatory lies almost on the direct line between Armagh and Aberdeen. The barograms for Stonyhurst and Halifax showed as little disturbance as Glasgow. At Dunecht Observatory the oscillation took place somewhat earlier and exhibited less intensity than at Aberdeen. At Bidston, however, which lies more out of the probable path of the depression than Stonyhurst, the oscillation is seemingly recorded with considerable distinctness. Temperature showed no appreciable change at Armagh, Glasgow, or Aberdeen. At the time of occurrence of the minimum a temporary change of direction and increase of velocity of the wind is recorded both at Armagh and Aberdeen.—The "arched squalls" of the neighbourhood of the trade-winds and of those regions where the monsoons blow with slight force and with interruptions, by Capt. A. Schück.

Physical Society, December 1.—Prof. G. C. Foster, president, in the chair.—Prof. Graham Bell exhibited and described the telephone before a crowded meeting of the Society, prefacing his account of the apparatus now so well known by a very complete historical sketch of the progress of electric telephony. The first experiments referred to were those of Prof. Page, who, in 1837, was studying the relation of electricity to magnetism, and found that if a coil of wire, traversed by a current, surrounds an iron rod, a sound like a pistol shot proceeds from this latter whenever the current is made or broken. He was followed by De la Rive, Poggendorff, Reiss, and others, but Reiss was the first to employ the human voice in his experiments. After pointing out that in transmitting sounds by electrical means the initial sounds themselves are in no sense transmitted but are only employed to generate currents which reproduce similar sounds, Prof. Bell proceeded to examine the phenomena which take place when sounds are transmitted through the air. It is, of course, not the motion of the vocal organs themselves that is received in the ear, but that of the air set in motion by their means, and all peculiarities in the sound must be peculiarities in the motion of that air. If the rapidity of motion varies it occasions a variation in the pitch, and the loudness is changed by changing the amplitude. The *shape* of the vibration produces timbre. If by moving the air in certain specified ways, certain vowel sounds are given out, then those same sounds will be emitted if an identical movement be occasioned by any mechanical means whatever, and Prof. Bell has found that such a motion may really be given to the air in various ways. Three classes of electrical currents have been employed for transmitting sounds to a distance, and these he denominates intermittent, pulsatory, and undulatory. The first form is obtained when a current passes for a brief interval, is then followed by an interval during which no current passes, and this by a current of the same or opposite sign. In the second class a current is continually passing, but its intensity increases and decreases instantaneously, and finally, in the third class this variation takes place gradually, and may therefore be represented by a sinuous line. In his experiments on the nature of the movement of the air Prof. Bell employed a human ear, a hay style attached to the incus recording the movement communicated to it on a moving sheet of smoked glass. A very interesting series of curves produced by this means was shown upon the screen, and he explained how his experiments in this direction led him to the present form of telephone. Since the very small membrane of the ear was capable of setting in motion comparatively large bones, it seemed probable that it could cause a light piece of iron to vibrate. In the earlier form of apparatus a piece of steel spring was therefore attached to a stretched membrane of gold-beaters' skin and placed in front of the pole of the magnet, but he found on increasing the area of metal that the action of the instrument was improved, and thus was led to do away with the membrane itself. Another branch of the investigation referred to the strength of the magnet employed, and this was modified by varying the strength of current. The battery was gradually reduced from fifty cells to none at all, and still the effects were observed, but in a much less marked degree; the action was in this latter case, doubtless, due to residual magnetism, hence, in the present form of apparatus, a permanent magnet is employed. Lastly, the effect of varying the dimensions of the coil of wire was studied, when it was found that the sounds became louder as its length was diminished; a certain length was, however, ultimately reached beyond which no improvement was effected, and it was found to be only necessary to inclose one end of the magnet in the coil of wire. A number of diagrams were projected on to the screen which showed the various forms the apparatus has taken from the time of Page to the present day. An air sung in a distant part of the building was distinctly heard in the room by the aid of an improved form of Reiss' telephone, lent by Prof. Barrett, and made by Mr. Yates, of Dublin. Prof. Bell, Prof. Foster, and Dr. Gladstone then carried on a conversation with a gentleman at a distance, and utterances were shown to be audible when the transmitting instrument was held about a foot from the mouth. A discussion then followed in which Mr. De la Rue, Dr. Gladstone, Profs. Foster, Guthrie, Atkinson, and others took part. In replying to the various questions, Prof. Bell stated that his attempts to determine the amplitude of the vibrations had not been successful, and he is coming to the conclusion that the movement must be molecular. Very distinct sounds are emitted when a considerable mass of iron is employed; and further, if the iron be glued to a piece of wood an inch thick and this be interposed between it and the magnet the action still continues. Conversation has been carried on through a distance of 258 miles, but a resistance of 60,000 ohms has been interposed without preventing the action. There is a very marked difference in the manner in which letters are reproduced by the telephone. Vowel sounds are more acceptable than consonants, and, as a rule, those letters are best transmitted which involve a large oral aperture in their utterance. Finally, he finds that high sounds are produced more fully than low ones, but this question has not yet received sufficient attention.

Zoological Society, December 4.—Prof. Newton, F.R.S., vice-president, in the chair.—Mr. Henry Seebohm, F.Z.S., exhibited and made remarks upon some of the rarer eggs and birds which he had obtained during his recent visit to the Arctic regions of the Yen-e-sey, in Eastern Siberia, and gave a rapid sketch of his journey. Some of the skins were interesting from the fact that they extended our knowledge of geographical distribution, such as *Phylloscopus trochilus* and *Acrocephalus schœnobænus*, from long. 88° E., *Anthus gustavi* of Swinhoe (*A. seebohmi* of Dresser, and *A. batchianensis* of Gray) from the same longitude, and young in first plumage of this species.—Mr. Saville Kent, F.Z.S., exhibited the plans of a Zoological Station and Museum and Institute of Pisciculture to be established at St. Helier's, Jersey. The object sought in the establishment of this institution was the provision within British waters of facilities for pursuing marine biological investigations similar to those which exist at the Zoological Station of Naples, and at the Andersen School of Natural History at Penikese Island, Buzzards Bay, U.S.A.—The Secretary exhibited, on the part of Mr. Andrew Anderson, F.Z.S., some specimens of natural history collected in India, amongst which were chicks of *Rhynchops* and specimens of *Podiceps cristatus* obtained breeding in North-Western India.—A communication was read from Mr. Henry Lee, F.Z.S., containing an account of the capture of a Risso's grampus at Sidlesham, near Chichester.—Mr. A. G. Butler read a paper in which he gave an account of a collection of lepidoptera made in Northern Formosa by Mr. H. E. Hobson.—A communication was read from the Marquis of Tweeddale, F.R.S., containing an account of a collection of birds made by Mr. A. H. Everett in the Island of Mindanao, Philippines. Eight new species were found in this collection, and were named *Tanygnathus everetti*, *Mulleripicus fuliginosus*, *Penelopides affinis*, *Criniger everetti*, *Orthotomus nigriceps*, *Æthopyga bella*, *Anthothreptus griseigularis* and *Ptilopus incognitus*.

Geological Society, November 21.—John Evans, F.R.S., vice-president, in the chair.—Oswald Fitch, John Hadkinson, B. Holgate, H. F. Parsons, M.D., and Edgar R. Rathbone, were elected Fellows of the Society.—The following communications were read:—On the glacial deposits of West Cheshire, together with lists of the fauna found in the drift of Cheshire and adjoining counties, by W. Shone, F.G.S.—The chair was then taken by Warington W. Smyth, F.R.S.—The Moffat series, by C. Lapworth, F.G.S.

Victoria (Philosophical) Institute, December 3.—Mr. C. Brooke, M.D., F.R.S., in the chair. The paper of the evening was read by Mr. J. E. Howard, F.R.S., and referred to the advances that modern science had made in regard to nature, and the value of "a slow but sure path of induction."

PARIS

Academy of Sciences, December 3.—M. Peligot in the chair:—The following papers were read:—On artificial production of corundum, ruby, and different crystallised silicates, by MM. Fremy and Feil. In a crucible of refractory earth is put a mixture of equal weights of alumina and minium, and calcined for some time at a bright red heat; after cooling there are found two layers, one vitreous, formed chiefly of silicate of lead, the other crystalline and often presenting geodes full of beautiful crystals of alumina. To obtain the red colour of ruby, about 2 to 3 per cent. of bichromate of potash is added to the mixture of alumina and minium. The silicate of lead on the ruby crystals is removed by the action of fused oxide of lead, hydrofluoric acid, or otherwise. A silicate of alumina (apparently dysthene) is produced by heating for some time a mixture of equal weights of silicon and fluoride of aluminium (fluoride of silicon is disengaged). Other reactions with fluorides giving crystalline bodies are described.—On invariants, by Prof. Sylvester.—On various means of accelerating the service in navigation-locks, by M. de Caligny.—Sir William Thomson was elected foreign associate, in room of the late von Baer, receiving twenty-seven votes against twenty-five for M. Van Beneden.—Report on a memoir of M. Hautefeuille, on reproduction of albite and orthose. M. Hautefeuille's process consists in keeping the elements of these minerals (free or combined), in presence of certain fused salts, such as tungstic acid and the alkaline tungstates. Thus a mixture of silica and alumina, in presence of an acid tungstate of potash at a temperature between 900° and 1,000° produces tridymite, orthose, and triclinic felspars. If the elements have been exactly proportioned, the tridymite and felspar disappear, and their elements go to increase the crystals of orthose.—On the law of absorption of radiations through bodies, and its use in quantitative spectrum analysis (first part), by M. Govi. This relates to a comparison of the curves of absorption given by wedge-shaped forms of the absorbent substance.—Practical tracing of the circle which has to be substituted for a given curve of finite extent, by M. Lécomté.—Battery in which carbon is the electrode attacked, by M. Jablochkoff. Into fused nitrate of potash or nitrate of soda is placed, as the attackable electrode, ordinary coke, and as the unattackable, platina. The electromotive force varies between two and three units, and thus exceeds that of the Bunsen and Grenet batteries. The coke may be lit and put in the nitrate in a powdered state. The gases developed by the battery are utilised. The containing vessels are of iron (that for the carbon, of iron wire).—Action of oxalic acid on silicate of soda, hydrated quartz, by M. Monier.—On M. Allaire's new method of purification of fatty water of surface-condensers, by M. Hetet.—On the respiration of submerged aquatic plants, by M. Barthelemy. These plants, observed in the normal state, do not liberate gas, even in sunlight, any more than aquatic animals (the liberation observed hitherto has been caused by experiment). The true respiratory act of these plants consists in absorption of air in solution in the water, probably by the roots.—A new one-liquid battery, by M. Jourdan. The electrodes are zinc and black-lead, the liquid an aqueous solution of sal alkali.—Occultations; graphic prediction, by M. Baills.—Observations of the spots and the rotation of Mars during the opposition of 1877, at the Rio de Janeiro Observatory, by M. Cruls. The time of rotation obtained from three values is 24h. 37m. 34s.—On a fundamental problem of geodesy; application of a general method of transformation of integrals depending on square roots (continued), by M. Callandeau.—On the rational integrals of the problem of geodesic lines, by M. Levy.—On the superficial tensions of aqueous solutions of alcohol and fatty acids, by M. Duclaux.—On some properties of boric acid, by M. Ditte. A lecture experiment is recommended, which demonstrates the liberation of heat in chemical actions. It is to add 125 grammes of water to 100 grammes of boric acid. The heat is such that an ingot of Darcet's alloy put into the mixture is fused in a few seconds.—On the formation of ultramarines and their coloration, by M. Guinet.—On the alterations of eggs, *à propos* of note by MM. Bechamp and Eustache, by M. Gayon.—On the mechanism of death produced by inoculation of anthrax in the rabbit, by M. Toussaint.—On some new mammalia of New Guinea, by M. Milne Edwards.—On compound machines, their economic produce, and the general conditions of their action, by M. de Freminville.—Process of registration and reproduction of phenomena perceived by hearing, by M. Cros (sealed packet).

GENEVA

Society of Physics and Natural History, October 4.—M. Alphonse Favre has found on the Allelin Mountain, dominating the upper part of the Saas Valley near Mont Rosa, a bed of euphotide. This name is applied to a rock formed of two elements, viz., saussurite, a leaden gray mineral, and diallage, a bright green mineral, classed among amphibolites. This bed explains the origin of the erratic blocks of that substance, which are seen in numbers in the plain occupied formerly by the Rhone glacier.—Prof. Wartmann showed two apparatus based upon the properties recently recognised by him among derived currents. One is intended to determine immediately the fraction of an electric current which traverses a given conductor. The other is a current-inverser, in which the production of the extra-current is avoided, because the current always finds its passage.

THE "INFLEXIBLE"

ON July 12 last we explained the *Inflexible* case at some length to our readers on the ground that there might be seen in it the beginning of a system which not only involved the safety of the four large and costly ships then commenced or contemplated, but which "having received countenance and sanction in the highest quarters in this country, may not improbably become extended over the navies of the world." A week later we considered the Parliamentary Papers on the subject, and came to the conclusion that the *Inflexible* was not a safe ship for battle, and that the objections brought against her had been much too lightly treated. Now that the Report of the Admiralty Committee is before us we are able—notwithstanding much that appears in it—to point our readers to it as a full and complete justification of the course we and others then pursued, for that Report concludes with these words :—"We therefore desire to bring under the very serious consideration of their Lordships the necessity, before proceeding with the construction of more vessels of the type of the *Inflexible*, of thoroughly investigating whether by more beam their safety may not be largely increased without impairing their speed and efficiency." As this appeal "to the very serious consideration of their Lordship's" in arrest of the construction of other ships of the type closely follows a paragraph in which the Committee show the very great advantages of an alteration in the form and proportions of the *Inflexible's* citadel (without increase of armour), it is not conceivable that the Board of Admiralty will proceed with the other vessels of the type, and it is absolutely certain that no more ships possessing the defects of which we complained in July will be laid down. The great object which we set before ourselves, therefore, is already accomplished, and the extension of a dangerous system of design throughout our own navy, and the navies of the world, has been effectually arrested. As we know that the case of the *Ajax* and *Agamemnon* was actually before the Committee, and as their Report makes no exception of them in their appeal to the Admiralty to stop further proceedings, it is to be inferred, we presume, that the beam of these two ships will have to be increased in accordance with the Committee's views. With these results before them all those who took part in bringing about this inquiry may, we think, be congratulated on the success and value of their labours.

There only remains the *Inflexible* herself to consider in the light of the Committee's Report; and in discussing this part of the subject we must not forget that no inconsiderable portion of the report, and especially the aspect which its opening pages presents, has been greatly influenced by the form of the Admiralty reference. We take leave to say that the first of the questions put by the Admiralty to the Committee has little or nothing to do with the subject. We do not remember that even Mr. Reed, who has most strongly condemned the *Inflexible's* design ever contended that "the blowing out of *the whole* of the stores and cork by shell-fire" would occur very early in an engagement; and if he had, the elicitation of a contrary opinion from the Committee would have no serious bearing upon the subject, simply because experiment, and experiment alone, can determine the degree and rapidity of the injury to which thin iron chambers filled with cork are liable. Mere opinions, in the absence of experiments, are comparatively valueless in such a case. But what we should have thought was absolutely self-evident, even without any experiment, is that shell-fire from modern ordnance would certainly blow cork packing out of thin iron chambers at some rate or other; and yet, strange to say, this is what the Committee appear to doubt, and even to deny, for they say that in their opinion that which may "be fairly assumed to represent the greatest amount of damage the ship would be likely to suffer in any action" is the condition in which, although the unprotected ends are completely riddled and water-logged, the cork and stores remain in place, and add to the buoyancy. It is fair to assume, then, according to the Committee, that in no naval action will the cork be blown out of place by shell-fire, and this in face of the fact that when an experiment was actually tried at Portsmouth the contrary result was experienced. It is of the utmost importance to note carefully that it is only by making the above extraordinary assumption—an assumption which we believe will not meet with the concurrence of scientific artillerists and seamen—that the Committee are able to oppose in any degree the opinions of the ship's danger which we and others expressed in the autumn. It is on this assumption that they rest their opinion that "the unprotected ends are as well able as the armoured citadel to bear the part assigned to them," and that therefore "a just balance has been maintained in the design." It unfortunately is made perfectly clear afterwards by the Committee that the "part assigned to them" is to hold the citadel and the rest of the ship upright, and it is clear that they cannot be presumed fit to perform this part if shell-fire can blow out the cork This is the weak point—we venture to think the dangerously and even fatally weak point—of the Committee's Report, and one which the common sense and observation of men will prevent them from assenting to, and consequently the *Inflexible's* safety is so ill-assured that we doubt if responsible persons will sanction the completion of such a ship.

The committee have fallen, as it appears to us, into a grave inconsistency, likewise, as regards the *Inflexible* herself. They say, as we have seen, that the unprotected ends are, as designed, well able to perform their part, and well balanced with the citadel. In subsequent passages, nevertheless, they go on to disclose and assert even more serious defects in them than any of us adverse critics of the ship have alleged, and to recommend an enormous extension of the cork chambers. What is the meaning of a scientific committee dealing with an extremely grave public question in this way? Either the unarmoured ends are well designed at present, or they are not; if they are, why alter them to the very large extent—far larger than a cursory perusal of the report might lead readers to expect, for the increase of cork chambers recommended is enormous? If they are not, why has the contrary statement been made and circulated? The truth is they have not been satisfactorily designed, as we shall presently prove from the Committee's own report. But first let us dispose of a long argument which the Committee enters upon and pursues with the object of proving that by lengthening the citadel you would thin the armour upon it, and thus reduce its defensive power. Assuredly you would: nor can any one doubt for a single moment that it would be far better to reduce the armour a little for the purpose of making the citadel stable enough to hold the ship upright in spite of any injury to the unprotected ends, rather than to keep the present thickness, and to reduce its length sufficiently to cause the whole to capsize when the unarmoured ends only are badly damaged. We know how naval officers answer this question. But, in truth, the whole argument of the Committee on this point is beside the mark, and a mere beating of the air, for no one that we know of has urged the change which the Committee take so much pains to discuss. What we have always understood Mr. Reed to allege, and certainly what we have in NATURE maintained is, that in the *Inflexible* the citadel and unarmoured ends were neither well-formed, well-proportioned, nor well-balanced against each other, and that a ship of her type should have embraced a larger area of flotation within the citadel and a less area within the unarmoured ends. And this is precisely what the Committee themselves declare, and thus refute their own assertion that the ship is properly designed at present. Near the end of the Report they say:—

> "Results which have been obtained in the course of the experiments at Torquay on the resistance of ships, show that a considerable increase of the extreme breadth of the *Inflexible*, if accompanied by a corresponding fining of the ends so as to keep the displacement unaltered, would, if anything, diminish the resistance of the intact vessel to propulsion at full speed. Supposing the ship thus increased in beam 10 feet, and the citadel shortened so as to retain the same perimeter and thickness of armour, her transverse stability would then be about doubled in the *e* and *f*[1] conditions, and in the riddled and gutted condition, would be more than it now is in condition *e* or *f*. Her longitudinal stability in the riddled and gutted condition would be reduced 10 per cent. (*t*, Appendix No. 15), but would not be diminished in condition *e*, and scarcely appreciably so in *f*. The increase of beam would also add to the area of the citadel in a horizontal plane, and thus increase the buoyancy in the riddled condition."

When the Committee, who lay down these clear and cogent proofs that the *Inflexible* is vastly inferior, in respect of stability and safety, to what she might have been, also tell us that "a just balance has been maintained in the design" of that ship, and that "a good result has been obtained," we find great difficulty in reconciling their statements, and feel strongly that if the public were to trust only to the language of the Report they might readily be led to draw extremely wrong inferences. We much fear that the gentlemen composing the Committee have thought too much of the Admiralty, with which they are all more or less connected, and too little of the public, who have been waiting for many months for their verdict. That verdict has been pronounced in a manner which, speaking on behalf of scientific men, we lament. It is inconsistent, and, so far as we can understand it, contradictory, in its several parts, and is in large part likely to beget in certain quarters a fatal confidence in a ship the defects and dangers of which the Committee evidently well understand. So uncertain and indefinite is it that it does not make it unquestionably clear even that the *Ajax* and *Agamemnon* are included in their desire to have progress arrested, for although after speaking of the *Inflexible* only they ask that no more vessels of the type may be proceeded with, and thus employ terms which cannot well be otherwise interpreted; the absence of all mention of their names nevertheless leaves room for the suggestion of a doubt on the point. It was clearly due to all concerned that their views on so weighty a matter should have been placed beyond all hesitation and question.

But those who would understand the full significance of this Report must not be deterred from perusing it carefully through, for if after reading thirteen out of its sixteen pages they were to throw it aside they would have derived from it, we say without hesitation, not only a very insufficient but a very untrue conception of the *Inflexible's* actual condition. Up to that point both a hasty and a deliberate perusal of it yields, to our minds at least, the impression that the Committee are admirers of the existing ship in almost every particular. But the disclosures which the scientific conscience of the Committee demanded and enforced commence on p. 14, and thence to the end facts of an appalling nature respecting her are gradually unfolded with so much effect that even the Committee themselves end by imploring the Admiralty not to repeat such a design! Let us briefly observe what these disclosures are.

The first relates to the inclining force which the action of the rudder exerts upon a ship of small stability. The Committee made experiments with the *Thunderer* expressly to acquire facts illustrative of the *Inflexible's* case, and the conclusion at which they arrived is thus stated:—"The *Inflexible* riddled and gutted,[1] and without water ballast, going at 7·24 knots, and turning in the circle of 1,210 feet in diameter, would require a righting lever or G Z of ·13 feet, and as the value of G Z at her maximum stability in this condition is only ·12 feet, *she would on this supposition overset.*" To soften down this alarming fact the Committee add: "It is, however, not to be expected that the ship under this condition could be driven at this speed"—a speed of 7¼ knots only round the circle, corresponding to only eleven knots in the *Thunderer* when steaming on a straight course! And this the reader will bear in mind is true of the *Inflexible*, not when her armour has been pierced by huge shells, or her bottom knocked about by rams and torpedoes, but when nothing but her exposed unarmoured ends have been badly injured. Her armour and her bottom may be perfectly intact, ay, untouched, and yet her own rudder would capsize her in steaming at a low speed. No statement ever made about the *Inflexible* by those who condemn her has gone or ever could go much beyond this. And what can be thought of the figures given? The line G Z is the lever or arm, at the ends of which the gravity and buoyancy of the ship act in opposite directions. The length required for withstanding the rudder's action under the given conditions was ·13 of a foot (1½ inches only [!]), but even that is more than has been allowed in the design of this ship (viz. ·12) in which the Committee say "a just balance" has been preserved.[1] And this inability of the ship to withstand her own rudder's action, and that at a low speed, even with virgin armour and a bottom untouched by ram or torpedo, having been asserted and urged by others, elicits no remonstrance or objection whatever from the Committee. And yet, when a little later on in their Report they have disclosed a somewhat similar degree of longitudinal instability—discovered, as they suppose by themselves, but already well-known and obvious, doubtless, to others—and have shown that the ship would not be safe at seven and nine knots speeds because of her tendency to capsize lengthwise (so to speak), and so more or less down headforemost, then the Committee see grave danger showing itself, for they say, "We consider that any large limitation in the ship's speed may expose her dangerously to the attack of ram or torpedo," and in the summary they incidentally tell us, in the mildest terms, that a blow from either would be fatal; "the small residuum of stability she would possess would not avail to render such an attack other than fatal." The only difference in the two cases is (and this is possibly the reason why the Committee lay the greater stress on this case) that it is not here necessary to suppose the cork or stores blown out, for a single shot or shell making a large wound near the stem, bulging a skin plate outwards, and completely rupturing the internal bulkheads, would so destroy the longitudinal stability of this large ironclad, costing more than half-a-million sterling, that even at seven knots' speed she would run her bows under; "and again," we are told by the Committee, "her speed is similarly limited to nine knots by wounds of a much less critical character in other parts of her sides." We have said that even this danger was doubtless foreseen by others—as it certainly was by ourselves, whether mentioned or not—before the Committee's Report appeared; but the Committee certainly have carried the subject a step forward by the experiments they have made with the model, and by their positive declaration that "on the whole the effect of sea-waves must be to aggravate, and in some circumstances greatly to aggravate," this very serious and certain source of danger. In a word, the very Committee who have in another place asserted that in the *Inflexible* the balance is fairly maintained between the armoured and unarmoured ends, have elsewhere in their Report shown that that balance is so ill maintained between the two, that with all the cork in place one or two shot and shell penetrating the unarmoured parts would so reduce her stability that she could not be steamed ahead with any reasonable speed, but would of necessity become a prey to any ram or torpedo craft that might evade or disregard her guns!

---

[1] These references *e* and *f*, are to the Parliamentary Papers, and represent the ship with the ends riddled and water logged, *e*, showing the coal as well as the cork, &c., in place, and *f* with the cork, &c., in, but not the coal.

[1] T[illegible]phrase, "The *Inflexible* riddled and gutted" is (improperly) emplo[illegible] by the Committee when they speak of the unarmoured ends being riddled and having the cork blown out.

Another disclosure of the Committee is that the mere running out of the guns "would become a serious element of danger as the ship approaches the riddled and gutted condition." Here again they employ the phrase to which we have already intimated an objection in a foot-note, and speak of "the ship" approaching "the riddled and gutted condition." They mean nothing of the kind; by "the ship" they mean the exposed unarmoured ends only; and here again it is to be observed that the danger disclosed is not one contingent upon the blowing out of all the cork, &c., but arises before, when the unarmoured part only *approaches* that condition. That the danger is, again in this case as in the previous one, a very serious and practical one is shown by the Committee recommending an alteration in the gunnery arrangements, proposing that the travel of the gun on the slides should be restricted, lest by running the guns out to the full extent at present arranged for, they should capsize the ship.

We have now sketched, sufficiently for our present purpose, the substance of the Committee's Report. We may end this article as we ended that of July 19, and repeat: "The conclusions we have arrived at are, that the *Inflexible* is not a safe ship for battle in her present state, that the objections brought against her have been much too lightly treated, and that the disclosure of her condition, with the circumstances that have followed it, have excited just surprise and dissatisfaction." That surprise and dissatisfaction will be greater than ever when the Committee's Report has had time to produce its full effects, both intended and unintended.

HYDROPHOBIA[1]

II.

We do not intend to do more than allude in a cursory manner to the prophylactic treatment of hydrophobia, *i.e.* to the treatment adopted to prevent the occurrence of the disease in those who have been bitten by mad dogs. The general experience of the past sanctions, as might be expected, the practice of attempting to prevent the absorption of the poison of rabies by excising or destroying by caustics the wounds inflicted by rabid animals; of the innumerable internal remedies which have been proposed and made use of with the object of preventing the development of hydrophobia in those bitten by rabid dogs, it may be said with justice that nothing whatever is known which warrants the assertions of their advocates. This is indeed a case in which the fallacies which beset all therapeutical inquiries, especially when attempted by ignorant persons and fanatics, are specially liable to obscure the truth. Of all dogs supposed to be rabid, only an infinitesimal proportion really are so, and it is but rarely that the fact of a dog being rabid is tested by having it watched until it dies, or by the unfortunate fact that some of those bitten perish by hydrophobia; then, of all persons bitten by certainly rabid dogs, only a small proportion become affected with hydrophobia, even when no treatment is adopted, so that the value of any drug or remedial measure as a *prophylactic* could only be tested by an experience such as no one ever has had.

Less uncertainty prevails in reference to the effects of treatment when hydrophobia has been developed. According to the best observers this disease has hitherto been invariably fatal. There are, it is true, a few cases—and of these two have been recorded within a comparatively recent period—in which a cure is said to have been effected, but when examined with care the gravest doubts of their real nature must be entertained. Here again there are fallacies to be encountered of no insignificant nature. The continued and terrible anxiety lest a bite which has been inflicted should be followed by its terrible consequences has led, in the case of persons of a susceptible and unstable nervous system—as all other long-continued worries and anxieties are liable to do—to the development of hysteria and insanity and, in the attacks of acute mania which have occurred in such individuals, many of the phenomena of hydrophobia have been imitated. An admirably-narrated case of this "hydrophobie non rabique" of French writers was lately placed on record by Mr. Hugh Norris, of South Petherton ("Hydrophobia or its Eikon—which?"—*Lancet*, September 22, 1877):—"A gentleman underwent terrible anxiety on account of his young son having been bitten by a dog which suddenly had become ill and strange in its behaviour. The danger which threatened the boy caused the father to become intensely emotional, and prolonged sleeplessness ensued. Other worries superadded themselves to this one great gnawing anxiety, and the poor man fell ill; at first there appeared symptoms which simulated very closely the hydrophobic phenomena, but these were succeeded by a genuine attack of acute mania, which necessitated the patient's removal to an asylum, where he died on the seventh day of his illness." In this case there was no evidence that the patient was actually bitten by a dog, his statement that he had been so injured having been made, in a peculiarly suspicious manner, only after his illness had commenced, and being apparently but one of the delusions which afterwards haunted him. Had this man been certainly bitten, and had his illness been followed, as it might have been, by recovery, his case would in all probability have been quoted as one of the few instances of recovery from hydrophobia, though the impartial critic would have pointed out some anomalies which rendered the conclusion doubtful. The knowledge of the undoubted occurrence of such cases necessarily imposes great caution in the examination of alleged instances of recovery from hydrophobia.

---

[1] The Committee, at the bottom of page 15, give us the means of readily illustrating the amount of stability which the *Inflexible* has in the case above considered, for they tell us that 60 tons in the bottom of the ship, which herself weighs over 11,000 tons, would alter the length of G Z to ·12 of a foot.

[1] Continued from p 119.

The drug to which attention has of late been directed for the treatment of hydrophobia is curare or woorara, a substance used by the natives of South America as an arrow poison. This poison has been known since the end of the sixteenth century, when Sir Walter Raleigh made the conquest of Guinea; but attention was drawn to it in a special manner by the celebrated traveller, Waterton, who first made experiments on animals with it, which were continued by Sir Benjamin Brodie and Dr. Sibson, and were succeeded by the now celebrated researches of Claude Bernard, Kölliker, and other eminent physiologists. Curare, the active principle of which is derived from a strychniaceous plant, when directly introduced into the blood or injected under the skin, produces paralysis of all voluntary movements; this paralysis depends upon its exerting a special action upon the terminations of motor nerves in the muscles, especially in voluntary muscles. The poison leaves intact the sensory nerves of the body, and at least in the early stages of its action, the nerve-centres. An animal subjected to its influence becomes absolutely motionless, and dies rapidly of suffocation from paralysis of the respiratory muscles; if, however, respiration be kept up by artificial means, life may be prolonged for long periods, and, the poison becoming eliminated, recovery may ensue. As long, however, as the stage of complete paralysis continues, the creature is entirely unable to communicate with the external world. There is no proof that external stimuli do not affect it; that it does not feel—but the channels by which the evidence of sensibility reach us are for the time interrupted. Curare has been suggested as a remedy for many diseases of a spasmodic character, but a great obstacle to its use is presented by the danger which attends its employment. A dose which will be sufficient to arrest an abnormal spasmodic contraction of a muscle or group of muscles, will presumably cause a stoppage of respiratory movements, and the medical man, if haply he be near the patient, will find himself compelled to keep up artificial respiration—no easy task to accomplish, especially with the means which the physician, as distinguished from the physiologist, could employ. Hitherto the attempts to use curare have been few, and the results (if we except the two supposed cases of cure of hydrophobia) we think worthless. Curare is indeed a drug the employment of which must be attended with so great a risk that a very strong case should be made out in its favour before patients are exposed to it.

Knowing as we do the physiological action of curare, we may ask whether it is a drug at all likely to be serviceable in spasmodic affections generally, and specially in hydrophobia. The majority of spasmodic diseases are due to a central cause, or to a cause acting through a preternaturally excitable centre. Any drug which will cut off—as curare does—the communication between the nerve-centre and the muscle will prevent its spasm, and will of course obviate any evil results which follow directly from the spasm; but, necessarily, under these circumstances the abolition of the spasm is no index that any change has been effected in the morbid state to which it owed its existence. In hydrophobia there occur, it is true, as prominent phenomena, spasms of the muscles concerned in inspiration and in deglutition. The administration of curare in doses sufficient to stop the respiratory movements would doubtless prevent these spasms, though we must not forget that it would do so at no mean risk. But are these spasms the proximate or remote cause of death in hydrophobia? We believe not. They are spasms which, as we tried to show, are probably dependent upon a morbid state of the medulla oblongata, with which is connected a morbidly heightened reflex excitability of that portion of the nervous system. But there is no evidence that curare would exert any influence in diminishing this abnormal excitability.

From our knowledge of the physiological action of curare we should not then be inclined to believe that it could affect in a beneficial manner the progress of the essential morbid processes of hydrophobia; it could but modify some of the painful phenomena which belong to it. Actually curare has been tried in several cases, but only twice has its administration said to have been attended with success, and these two cases cannot be accepted as having been certainly cases of hydrophobia. We have seen one case of hydrophobia treated with curare without any influence having been exercised by it. There are drugs, however, which the physician is habitually employing that possess actions which would cause one to predict that they would be of special use in controlling the terrible spasms of hydrophobia, *e.g.*, bromide of potassium, chloral, and Calabar bean. These drugs all diminish in a signal manner the reflex excitability of the nerve-centres; and the second in the list possesses in addition powerful properties as a hypnotic; they have all been used in the treatment of hydrophobia; and one of them—chloral—has, in sufficiently large doses, been successfully used, in so far as relief of suffering was concerned. But as for a *cure* for hydrophobia it has yet to be discovered; and this remark applies to all zymotic diseases. The majority of these diseases, unlike hydrophobia, tend naturally towards recovery rather than death, and the physician is undoubtedly able, by judicious measures, to obviate the tendency to death. He cannot *cure* the disease, however, in the sense in which he might be said to cure it were he able to destroy the poison which is its cause; apparently, once introduced into the system the poison must produce its effects—intense or slight—which must have a certain course, and then cease, because the poison which induced them has passed away, or because the soil which nourished the poison supplies it no longer with the conditions which it required. But the day may come, and we believe will come, when even this great result may be achieved; when not only shall we know the conditions which attend the spread of zymotic diseases so accurately that we shall be able to prevent their spread, but when medicine may supply us the means of dealing directly with the *materies morbi* of the diseases, as, for instance, by "sterilising" the soil in which they are implanted.

Our general review of the main facts in the history of rabies and hydrophobia has naturally brought out with considerable clearness how little is known concerning it, and how much remains to be done. We hail, therefore, with satisfaction the appointment of a Committee of the British Medical Association charged with the investigation of this important and interesting subject. This Committee consists of Dr. Lauder Brunton, Mr. Callender, Mr. Ernest Hart, and Prof. Burdon-Sanderson.

Before concluding, a few words concerning the measures to be adopted for preventing the spread of hydrophobia.

From our insular position we are in a better position than any neighbouring nation for holding a check, or even "stamping out" such a disease as hydrophobia, which, as the vast mass of evidence tends to show, does not originate spontaneously, nor does it appear that it would be difficult to effect this result were the suggestions which have been made by several recent writers carried into effect. It is certain that the number of dogs kept in England is enormously in excess of any requirements, and it is equally certain that this state of matters might promptly be put a stop to. The existing dog tax need not be increased in amount, but it should be enforced in the most stringent manner, the business of collecting, prosecuting, &c., being handed over to the police authorities of each district. Each dog should have a separate number on the local register, and might be the wearer of a collar bearing its registered number. Further, the licence should bear a description of the premonitory symptoms of rabies, and owners of dogs should be cautioned instantly to report any suspicious case to the police. These regulations would, as a necessary result, lead to each dog being individually looked after and cared for, and would, we believe, in the course of very few years, lead to the disappearance of rabies.

DIEN'S "CELESTIAL ATLAS"

Atlas Céleste, comprenant toutes les Cartes de l'ancien Atlas de Ch. Dien. Rectifié, augmenté, &c., par Camille Flammarion. 3^{e} édition. (Paris: Gautbier-Villars, 1877.)

THIS is a new and enlarged edition of Dien's "Atlas Céleste," which first appeared in 1864, with the co-operation of M. Babinet, and is brought out under the editorship of M. Camille Flammarion. That the formation of the atlas, both in its original and extended plan has involved a great amount of labour will be evident upon a very superficial examination. The first issue was said to contain upwards of 100,000 stars and nebulæ, of which 50,000 had been observed by Lalande, projected on the development of a sphere, sixty-five centimètres in diameter, their places being reduced to the year 1860, and this scale was stated to be sufficiently large to allow of the insertion without confusion of all stars to the ninth magnitude inclusive. The charts were said to contain "nearly the totality of stars in the catalogues of Lalande, Herschel I., Piazzi, Harding, Struve, Bessel, Herschel II., Groombridge, and Argelander," while for the southern heavens recourse was had to the catalogues of La Caille and Brisbane. This description of the authorities consulted is not very definite. The reference to Harding must apply to his atlas; that to Bessel may be supposed to at least include the catalogue of equatorial stars observed by the Königsberg astronomer, which was prepared by Weisse of Cracow, and published in 1846, if not the second catalogue founded upon Bessel's observations, containing stars from 15° N. to 45° N. declination, also reduced by Weisse, which appeared in 1863. The reference to Argelander is especially indefinite; we have the well-known catalogue of 560 stars, and the "Uranometria Nova," but previous to the year 1864, when "Dien's Atlas" was published, astronomers were also in possession of vols. 3, 4, and 5 of the "Durchmusterung," with the results of the survey of the whole northern heavens.

The programme originally prepared was a very extensive one. The new edition is stated to have received numerous corrections and considerable enlargement to bring up the work to the actual state of astronomical science, and there is sufficient evidence that an attempt has been made in this direction, but we regret to have to express the opinion, after a close examination of the "Atlas," that in its present state it does not fulfil the programme upon which it was formed. It will soon be evident, on comparing the maps with the charts issued by the Berlin Academy, or more generally with those in the original edition of Harding's Atlas, that so far from containing stars to the ninth magnitude inclusive, numerous eighths, and even stars of 6·7 magnitude, are omitted, and it is not easy to see from what cause. It might be inferred that Bessel's catalogue of equatorial stars had not been utilised, since stars of the seventh and eighth magnitude observed by Bessel and not observed by Lalande, are wanting. But in addition we soon miss stars that do occur in the "Histoire Céleste," as for instance L. 39836, a star which Lalande considered a sixth magnitude.

Different views will be taken with regard to the proper contents of a celestial atlas, intended for general use, and it is not nerefore desirable to be too critical upon this point, but to take, we will say, two extreme uses to which an atlas of the pretensions of Dien's may be applied, first for following a small planet with the aid of a chart professing to contain stars to a less degree of brightness, and secondly, for identifying the naked-eye stars by the general maps including only these brighter stars, an elementary purpose for which an atlas may be quite as readily adapted as a globe. In the former case Dien's maps are not sufficiently filled in to allow of a planet equalling in brightness stars of Bessel's ninth magnitude being identified without some trouble and disappointment, and in the latter case we meet with a failing which is only too common with star-atlases—the outlines of constellations are so prominently drawn as seriously to interfere with, if not entirely to obliterate the naked-eye stars of the lower magnitudes, in using the "Atlas" in the open air. As a model of what an atlas should be in the latter respect, we must still refer to Argelander's "Uranometria," which, in our opinion, has yet no equal for the more elementary uses of such a work.

Among the best features in the new edition of Dien's "Atlas" are the delineation of the southern heavens, in which Brisbane's stars are laid down, the view of the distribution of double and multiple stars by M. Flammarion, the orbits of some of the principle revolving double-stars, and figures of remarkable nebulæ and clusters of stars.

OUR BOOK SHELF

Horticulture. By F. W. Burbidge. With Illustrations. (London: E. Stanford, 1877.)

THIS is one of the series of small handbooks on the British maufacturing industries, edited by Mr. G. Phillips Bevan, of which we have already noticed several volumes. A compact work on practical gardening, to serve as a guide to the amateur gardener and fruit-grower, was much wanted, and this volume to a certain extent supplies the desideratum. After a short chapter on commercial gardening, the author treats of the cultivation of fruit, and of the various descriptions of vegetables and herbs; and then of gardening in its various departments, but more from the economical than from the amateur's point of view. If the owner of a garden wants to turn his bit of land to the most profitable account, he will find Mr. Burbidge an admirable guide; but if he infers from the title of the book that he will obtain from it advice as to the treatment of his pelargoniums, fuchsias, and chrysanthemums, or the management of his hothouses, he will be disappointed. We fancy that information of this kind would commend itself to a larger number of readers than the guide-book information of the exact number of acres in each of our London parks, and the annual cost of maintaining them. The advice as to the culture of fruit and vegetables seems to us very good; but the rather poor woodcuts do not add to the value of the volume.

Mittheilungen aus dem k. zoologischen Museum zu Dresden. Herausgegeben mit Unterstützung der General-direction der königlichen Sammlungen für Kunst und Wissenschaft, von Dr. A. B. Meyer, Director des königlichen zoologischen Museums. Zweites Heft mit Tafel. (Dresden, 1877.)

IN a former volume of NATURE (vol. xiii., p. 464) we have given some account of the origin of this meritorious work, of which the second portion is now before us. Like the former half of the first volume of the contributions the present section is chiefly occupied with memoirs based upon the collections made by Dr. A. B. Meyer during his well-known expedition to New Guinea and the adjacent islands. Herr Th. Kirsch, the entomologist of the Dresden Museum, commences with two articles upon the lepidoptera and beetles collected by Dr. Meyer in New Guinea. Of the former Herr Kirsch enumerates 167 species, of which 133 belong to the diurnal section. Several novelties are described and well figured. The next article is by Dr. Meyer himself, and gives us an account of a large series of Papuan skulls which he collected on the mainland of New Guinea and in the Island of Mysore, in the Bay of Geeldink. The collection, embracing altogether 135 examples, is, we believe, by far the finest of this branch of the human family ever made, and should, we suppose, lead to some definite results upon that somewhat mysterious subject—the differentiation of the various races of mankind by their skulls. A second article by Dr. Meyer relates to the specimens of anthropoid apes in the Dresden Museum. We cannot say that the photographic plates of the stuffed specimens of these creatures are either elegant or likely to be of very great use, but it is satisfactory to have the vexed question of the identity of the celebrated "*Mafoka*" lately living in the Zoological Gardens at Dresden, and long supposed to be a gorilla, finally set at rest, as is done by von Bischoff's article on its anatomy, which follows that of Dr. Meyer. A memoir on the Hexactinellid Sponges collected by Dr. Meyer in the Philippine Seas, in the preparation of which Herr W. Marshall has given his assistance, concludes this interesting volume, of which we may say that it adds materially to the status of the Dresden Museum, and to the scientific fame of its energetic director.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.]

The Radiometer and its Lessons

I AM obliged to ask you to allow me to add a few words, by way of further explanation, to my letter printed in NATURE, vol. xvii. p. 80.

In trying to estimate the effect of the communication of heat between a solid body and contiguous gas, I have assumed that certain simplifying suppositions may be legitimately made, for the most part identical with what are very commonly adopted in discussing the pressure exerted by a gas on a solid in contact with it. That is to say, I have assumed, first, that we may resolve the velocities of the molecules of gas into three rectangular components, one perpendicular to the surface of the solid and the other two parallel to it; second, that we may conceive of the whole number of molecules as divided into three equal parts, one-third moving in the direction of each of the resolved components of the velocity respectively; third, that the mutual pressure between the solid and the gas, and any communication of heat from one to the other, may, for the purpose in hand, be attributed to *direct* impacts of molecules against the solid surface; fourth, that all the molecules endowed with a velocity perpendicular to the solid surface, and contained within a layer adjacent to this surface of a thickness not greater than the mean length of path, will strike the surface, while none of those which are outside this layer will ever reach it; fifth, that the particles which have struck the solid surface will return from it with an average velocity corresponding to the te[illegible]rature of the surface, and will retain this velocity until they arrive at the farther side of the layer before-mentioned. It was on the supposition that these are legitimate assumptions that

I spoke of heat passing across a stratum of gas from one solid surface to another "*as though* there were, in contact with each solid surface, a layer of gas whose temperature is throughout the same as [it would perhaps have been better to have said "determined by"] that of the contiguous solid."

I am fully aware of the ease with which one may be led into serious mistakes by trusting too implicity to such simplifying assumptions, and also that some of the particular suppositions made above would be inadmissible in a discussion of the general problem of the conduction of heat in gases; but I do not see any fallacy in employing them for the special purpose which I had in view in my last letter, namely, to show why I think that the flow of heat across a thin stratum of gas must be facilitated by diminishing the pressure of the gas. Prof. Osborne Reynolds's argument that "if there were a layer of uniform temperature, no heat would be transmitted," does not appear to me to be applicable to the case in question. It seems conceivable, as an extreme case, that, in a very thin layer of gas, between parallel solid surfaces maintained at different temperatures, the molecular movements might take place exclusively in the direction of the perpendicular to the bounding surfaces. In such a case the particles would move from side to side of the layer of gas with a uniform velocity, though the velocity one way would be greater than the velocity the other way, and heat would be transmitted across a layer of gas having the same temperature throughout. Such a condition, whether practically realisable or not, would, if I understand him aright, be the limiting case in one direction of what Mr. Stoney has called for shortness a "Crookes's layer:" the limiting case in the other direction being the ordinary condition of a gas, where the average velocity of the molecules is independent of direction. I venture to think that, in pointing out the results which must follow from the existence of a predominating direction of molecular motion, Mr. Stoney has made a very important contribution to the kinetic theory of gases; and I do not see that his conclusions are in any way invalidated by its being shown that they are not in harmony with "the generally-accepted laws of gases," inasmuch as these laws are deduced from suppositions which expressly exclude the conditions he has investigated. G. CAREY FOSTER

December 17

ALLOW me to say a few words on what I believe to be the correct theory of the radiometer. This theory was given to me by Prof. Osborne Reynolds during spring of 1875, and I have found it capable of explaining every experiment on the subject with which I am acquainted.

The conservation of momentum is one of the laws of nature which even molecules do not break, and that law puts some restraints on the wonderful things which the shocks of molecules can accomplish. Imagine a vessel full of gas at a certain temperature. The centre of gravity of the gas and that of the vessel are supposed to be at relative rest. Suppose now that I increase the velocity of a certain number of molecules in a given direction, the centre of gravity of the gas will move relatively to the centre of gravity of the vessel, and no number of encounters between the molecules can alter that motion until the momentum has been taken up by the vessel. If in any gas we have a passage of heat in a certain direction, we shall have a propagation of momentum owing to the fact that the molecules move more quickly in one direction than in the opposite one, and no number of encounters can alter that propagation. Where the momentum enters the gas and where it leaves it we observe certain forces. This is Prof. Reynolds's theory of the radiometer. It has been objected that an increased pressure on the cool side of the vanes of a radiometer will counterbalance the force acting on the blackened sides, when the dimensions of the vessel are large compared with the mean path of a molecule, but I do not think that such is the case. The following special case may make this point a little clearer. If the forces on the vanes are counterbalanced, the forces on the vessel must be counterbalanced as well. In the case of an ordinary radiometer the forces reduce to a couple, and I do not see how any crowding of molecules in one part of the vessel more than in another can produce a couple on the vessel. The whole problem is one of conduction of heat. All the experiments made by Mr. Crookes on cups, inclined vanes, &c., admit of the same easy explanation as the fact that when a long and a short wire are connected with the poles of a battery, the current in the shorter wire will be the strongest. In a radiometer with inclined vanes, for instance, the temperature is the same on both sides, but the gradient of temperature is much larger on one side, and hence more heat will escape on that side. The dimensions of the vessel also have to be taken into account in the same way as the length of a wire has to be taken into account when the strength of an electric current flowing through it has to be calculated. It is difficult to say exactly what takes place within very small distances from the hot surface, but it seems clear that any phenomenon, such as Prof. Carey Foster supposes to exist, must affect the passage of heat in the same way as the force on the vanes. As the careful researches of Messrs. Kundt and Warburg have shown that under great exhaustion the conduction of heat decreases and does not increase, I do not see how an increase in the force can take place.

The scientific world will judge how far Prof. Stoney has succeeded in establishing any new laws on the conduction of heat through gases. In justice, however, to Messrs. Provostaye and Dessains, whose experiments he calls to his aid, I wish to point out that their numerous experiments, with two exceptions, are in entire accordance with existing theories. At the time these experiments were made, no distinction was drawn between convection and true conduction. In order to deduce, therefore, the loss of heat due to true conduction, Prof. Stoney is obliged to subtract the effect due to convection currents. He draws, therefore, a curve representing the loss of heat due to this cause. All his conclusions must stand or fall with this curve, and I am afraid they must fall.

After Professors Clausius and Maxwell had deduced theoretically the coefficient of conductivity for gases, a series of celebrated experiments were made by Stefan, by Narr, by Plank, by Winkelmann, and last, but not least, by Kundt and Warburg. The influence of convection currents has been fully discussed in these papers and eliminated, and the conclusions arrived at by all these experimenters are fully in accordance with each other and with theory. It appears, as was expected, that when the effects of convection currents are eliminated, the coefficient of conductivity is independent of pressure until the dimensions of the vessel are comparable with the mean free path of a molecule, and that then the conductivity rapidly diminishes. It also appears that at the pressures at which Messrs. Provostaye and Dessains found that the loss of heat was independent of pressure, convection currents must have ceased to be appreciable, and therefore the great mass of their experiments is fully in agreement with later researches.

The only exception is found in the case of carbonic acid and nitrous oxide. These abnormal results were not confirmed by Messrs. Kundt and Warburg in the case of carbonic acid, the only one of the two gases which they examined. Whoever reads their account of the difficulty they had in excluding the last traces of moisture, and considers the increased conductivity which such an admixture would produce as the pressure diminishes, will have no difficulty in explaining the anomaly. At any rate I do not think Prof. Stoney will be inclined to base important conclusions on unconfirmed experiments on two gases in which we should expect the effect, owing to their density, to be particularly small. The discovery of Master Gerald Stoney, who found that a red hot wire was cooled when a tin can containing water was brought sufficiently close might, I think, have been foretold by the recognised theory. Prof. Stoney, no doubt, will find on reading over the literature on the subject, that what he calls penetration of heat, has hitherto been known under the name of conduction of heat, that it takes place at all pressures, and begins to disappear at the exact point at which he makes it appear.

The timely calculation of Mr. S. T. Preston in the August number of the *Phil. Mag.*, shows that any theory of the radiometer which makes the action depend on the comparatively large ratio of the mean free path to the dimensions of the vessel, must necessarily be wrong. ARTHUR SCHUSTER

The Proposed Channel Islands' Zoological Station, Aquarium, and Piscicultural Institute

I AM very anxious that this project[1] should succeed, mainly because of the facilities it will afford to inland aquaria, in procuring living animals cheaper, better, more variedly, and more systematically, than at present. This, I believe, will form the most profitable part of the undertaking.

[1] Referred to in NATURE, vol. xvii. p. 102,

I hope, also, it may succeed as a sort of living museum, without any of the kind of attractions which are not biological ones, and which, indeed, are not scientific in any sense, as common and ribald music, theatricals, acrobatic and jugglery performances, and so forth. Only, no aquarium has ever permanently thriven without these things.

I greatly doubt whether anyone yet possesses the requisite knowledge to be able to rear any marine crustacean from the egg state to an adult condition, and to feed it in captivity in such manner as to be able to sell it in the open market at rates below those sold under present circumstances. Yet this is put forward, conspicuously, as one of the aims of the scheme. In Britain are eaten as human food about a dozen species of crabs, lobsters, prawns, and shrimps, and most of these have been occasionally bred in aquaria as far as the Zoea state, when they are free swimmers, and they then generally die. Rarely, some few have been brought up to a higher stage, but I know of no instance, during twenty-five years of experience, where any marine crustacean of any kind has been reared to an adult condition in an aquarium. And if such a thing could be done, I believe that to feed them in any state of captivity, with animal food, which they require in great abundance and variety, and which must be purchased, would be very expensive, indeed, far too costly I think, to be practically and commercially remunerative.

I am glad to see that in last week's NATURE, vol. xvii. p. 133, it is stated that that excellently-tasted little fresh-water lobster, *Astacus*, has been bred artificially by a Piscicultural Institution at Schwerin. If so, why should it not be similarly bred in Britain, where it is much seldomer eaten than in France and Germany. In Berlin, Hamburg, and Dresden, I have often purchased it at sixpence a dozen, while in Paris I have given as much as sixpence each for it. It is a pity, however, that the Schwerin account is not more full and explicit. It is stated that in the spring of 1876, 700 *Astacus* in egg, were placed in two round ponds, each of six feet diameter. Holes were made in these, and recently, on draining the ponds, only three or four adult crayfish were found straying about the ponds, the rest each being in a separate hole, and a large number of young ones were found, as big as bees, and very lively. What size were the crayfish at birth, and if very small, and swimming, how were they prevented from escaping from the ponds? Information is wanted as to the shape, length, breadth, direction as to angle, and distance apart of these holes, and their position in the ponds, whether in the sides or base, or both. If nearly 700 animals occupied as many holes, where were the young ones? How many young were there? If each female had only as few as 100 eggs hatched out, then 70,700 must have been the population of these two little pools. When, and in what manner, were the males introduced? We require also to be told of the material of which the ponds were constructed, and if the sides were upright, and the bottoms flat, or if rounded or basin-shaped. If water ran in and out, how much in a named time, of what quality, as to foreign substances it contained in solution and suspension, and what was its temperature at various periods of the year? In what direction and in what amount was light admitted? How much vegetation, and of what kinds, grew in the ponds? What kinds of animal food was given them, and how much and often, and was it cooked or raw? Carrots appear an odd food for crayfish. Let all these things and more, be carefully ascertained, to see if they can be applied to the culture of *Homarus*, the near marine relative of *Astacus*, before much money is spent.

It would be an excellent thing for students to have a place to study at, such as is proposed to be provided for them at Jersey, and similar to the zoological station and aquarium at Naples, in the arrangement of which I had much to do. But would students be content to go only so far as Jersey? Is not the access too easy, and too cheap, as it is not easy or cheap to go so far as Naples, and to have the *name* of so going? I have often thought it odd, and evincing not at all a really zealous spirit in my own direction on the part of my fellow-naturalists, that such a thing should be, that though the Crystal Palace Aquarium has existed for seven years within less than one hour's railway ride from London, and though it contains a constantly advertised collection of living marine animals exceeded in variety and interest by none in Britain, or even Europe, yet no scientific man, except the late Edward Newman, has ever applied for permission to carry on any course of inquiry here on any subject, continuously or occasionally, connected with the habits of living creatures, in the spirit of say, Gilbert White of Selborne. Yet we offer all such advantages as table-space, good light, and the use of any animals in our tanks not having a considerable money value—lest injury be done to such specimens—absolutely free of all charges. At this moment we possess many Italian animals in our collection, as fishes, crustaceans, mollusks, zoophytes, &c., which can be seen alive nowhere else, save on the shores of the Mediterranean, and yet no professed zoologist known to me ever comes to see them, or takes the smallest interest in them. They are therefore beheld only by the general public, who only look at them for their mere prettiness, or for what untrained observers are complacently pleased to term "ugliness." No student ever asks us for more than any dead animals we may chance to have, and which we give away gratis, and these apparently afford far more pleasure than the sight of living specimens. It is not at all uncommon to meet with biologists who openly and avowedly proclaim their contempt for collections of living animals in aquaria, which they regard as being "well enough for women and children," but for *men* they say there is nothing like seeing such animals in rows of glass jars of alcohol on the shelves of a museum. My last contribution of any length to NATURE was made so long ago as October 12, 1871, when I gave a description of the Crystal Palace Aquarium, then only just opened. Since then we have had no cause to complain of the appreciation of the world of sightseers. But as regards the indifference of the scientific world, that has been and is so great that the place might never have existed. William Yarrell, the British ichthyologist of the generation just passed away, used to tell me how glad he would be to see a live John Dory (*Zeus faber*), and how much he would give to behold one swimming. But here, at Sydenham, this fish can be seen alive and in perfect health for months together, in crystalline sea-water. Yet no Yarrell ever comes to see them. Are there no Yarrells, and Whites, and Watertons, and Newmans now? or has their very spirit passed away into the region of apathy where the affectation of caring for nothing, and of being never moved to zeal in anything, in this observation of live animals, seems to be regarded as a very high accomplishment?

The "Challenger" Estimates of the Volume of the Gulf Stream

IN the interesting "Voyage of the *Challenger*," just published, Sir Wyville Thomson states (vol i. p 371) "that the Gulf Stream in its restricted sense was, early in May, 1873, at the point where we crossed it and made our observations, about sixty miles in width, 100 fathoms deep, and its rate three knots an hour." I was much surprised at reading this, as the Admiralty Report on Ocean Soundings, No. 7, p. 12, estimates it at the same point as "100 fathoms deep, and running at the rate of three miles an hour *for a width of fifteen miles*, discharging four and a half cubic miles of heated water per hour."

As no reference is made by Sir Wyville Thomson to the extraordinary discrepancy in these two estimates of the same thing at the same time—one being four times the volume of the other—and as he says he makes the statement "thus guardedly" I think, in the interest of scientific accuracy, an explanation is required.

Liverpool, December 8

The Fossil Peronospora as a Primordial Plant

THE concluding sentence of your notice (vol. xvii. p. 128) of my observations on a fossil fungus is so important, that I shall be glad of a word of reply. You say, "But should not this primordial plant have led a non-parasitic life? for if parasitical, then this fact points to some pre-existing plant."

Although the specimen I have figured is shown as growing within the decayed tissues of a Lepidodendron, yet it does not follow that the same fungus could not perfect itself on humus alone. Recent species of Peronospora show a tendency to grow upon the ground, as several species, including the fungus of the potato disease, will grow and produce fruit on the naked earth. A truly terrestrial species is found in the allied *Botrytis terrestris*, Persoon, and many of the Mucedines grow freely in cellars, on damp walls, or in any moist place.

THE "CHALLENGER" IN THE ATLANTIC[1]

THE *Challenger* left Portsmouth on December 21, 1872, and on the evening of May 24, 1876, she dropped her anchor at Spithead after an eventful voyage, which lasted three and a half years. Shortly after her arrival we gave a sketch of her cruise over the Atlantic and Pacific Oceans. The two volumes just published consist chiefly of an abstract of the less technical portions of the journal kept by Sir Wyville Thomson during the first year of the *Challenger's* voyage, and during the early part of the fourth year's voyage, when she was on her way home. During both these periods the *Challenger* was in the Atlantic, so that we now obtain the record of her survey of this great ocean in a very complete form, and are led to look forward to several additional volumes, in which the account of her cruise in the Pacific Ocean and amongst its fair islands will appear. A great deal of credit must be given to the author of these two splendidly illustrated volumes for his so speedily publishing them. A large portion of one of them was actually passed through the press while the *Challenger* was at sea, and the preparation of the second volume had to be carried on amid the cares not only of professional duties, but also of getting the immense collections made into order, and of making arrangements for the thorough working out of the scientific results of the voyage. May we express the hope that his energy will enable him speedily to complete the popular narrative of this cruise thus so auspiciously begun. The strictly scientific records of the *Challenger* voyage cannot be published for some time; the working out of old forms, the describing and illustrating of new ones, takes time; such work, to be done well, must necessarily be done slowly, and hence we all the more urge on Sir Wyville Thomson to let us have, as soon as can be, the completion of the popular narrative of the general results of his four years' work. This preliminary account is indeed not solely a popular one, for we find in these two volumes a mass of exact scientific details that will make them always works of reference to the scientific student; and while some few of the wondrous new species of animals and plants are but incidentally introduced to us, their descriptions are often so well written, and their forms are so exquisitely portrayed, as to leave us for the time somewhat independent of their more exact scientific diagnosis.

In our previous sketch of the voyage of the *Challenger* we dwelt somewhat in detail on the work accomplished by her during the first six months of 1873. About the middle of June in that year she left the Bermudas for the Açores and Madeira, establishing twenty-five stations on her way, some of these showing ocean depths of 2,800 fathoms. A few pleasant days were spent (July 1873) at Ponta Delgada, the capital of San Miguel and the chief town of the Açores. On acccount of the presence of an epidemic of small-pox no delay was made at Madeira, but the vessel's course was struck for the Canaries and Cape de Verde Islands, keeping somewhat parallel to the Coast of Africa until nearly opposite Cape Palmas, when they turned westward and shaped their course to Saint Paul's Rocks. These solitary rocks are nearly under the equator, midway between the coasts of Africa and of South America. They were visited in 1832 by the *Beagle*, and are noticed in Darwin's charming "Voyage of a Naturalist." Merchant-vessels usually give them a wide berth. They seem to have struck the travellers by their small dimensions; it being rather under a quarter of a mile from the one end of the group to the other, they form quite little specks of rocks out in mid-ocean. Landing on these rocks was no easy matter. A loop of eight or ten ply of whale-line was passed round one of the rocks; to this a hawser was run from the ship lying about seventy yards out, with her bows in 104 fathom water; the hawser was made fast to the whale-line, and the ship thus moored to the rocks. Having landed on the rocks a line was laid across the mouth of the cove, which made the landing easier for the next parties.

Only two species of birds were found on the rocks, the "booby" (*Sula fusca*) and the "noddy" (*Sterna stolida*), both being widely distributed birds on tropical islands and shores. They were here in enormous numbers, were quite tame, even allowing themselves to be taken up with the hand. The breeding season was over. No land plants were found, not even a lichen. The terns used a green alga to line their nests; all the crannies of the rock were crowded with an amphibious crab (*Grapsus strigosus*), which was much more wary than the birds, though "wherever a morsel of food came within their reach there was instantly a struggle for it among the foremost of them, and they ambled away with their prize wonderfully quickly: their singular sidelong gait and a look of human smartness about them had a kind of weirdness from its being exhibited through a set of organs totally different in aspect from those to which one usually looks for manifestations of intelligence."

Leaving these desolate rocks on August 29, the island of Fernando Noronha was in sight on September 1, rising like most of the ocean islands, abruptly from deep water, the depth of the ocean within six miles of the island being more than 1,000 fathoms. This island presents a most remarkable appearance; the land is generally not very high, but there is an irregular cliff which rises to a height of about 100 feet from the sea, succeeded by undulating land and conical hills, usually covered with luxuriant vegetation. The Peak is an extraordinary-looking mountain, formed of a column of rock which starts up to a height of 600 feet from a more or less level plateau of rock, itself some 400 feet above the sea. There is a village and a citadel, the place being a penal settlement belonging to Brazil. There were at the time on the island nearly 1,400 convicts and a garrison of 200 soldiers. The convicts enjoyed a considerable amount of liberty, each of them occupying a hut, and being allowed to cultivate a little piece of garden ground, though their time and labour from six in the morning until four in the evening belonged to the Government. Sir Wyville Thomson and his assistants were extremely anxious to investigate thoroughly the flora and fauna of this island, but unfortunately the military commandant set his face against this, and the land work had to be abandoned.

"The coast scenery was here and there very beautiful, little sandy bays with a steep cultivated slope above them, or a dense tangle of trees absolutely imbedded in one sheet of matted climbers, separated by bold headlands of basalt or trap stuff. Besides the tropic birds, there were to be seen beautiful little terns, snowy white, which usually flew in pairs a foot or two apart, one following all the motions of the other, like a pair of paper butterflies obedient to the fan of a Japanese juggler. They could be seen flying over the land, and often alighting upon the trees. The noddy was very common, and the booby was in considerable numbers. High upon the cliffs the nests of the frigate bird (*Tachypetes aquila*) could be seen, and from time to time these splendid birds moved in slow and graceful circles overhead." No wonder that the author adds, "We lay for some time below the cliffs admiring the wonderful wealth of animal and vegetable life ere we returned slowly to the ship."

On September 14, as they neared the coast of Brazil, a shower of butterflies fell on the ship, fluttering in multitudes over it; and over the sea as far as the eye could reach they quivered in the air. Looking up into the sky where they were thickest, they were seen to be close together and had much the appearance and peculiar motion of large flakes of snow. Amidst such a downpour the entrance to Bahia was seen. It is very beautiful; the coast is not elevated; it is neither mountainous nor hilly, but rises from the sea-shore in even terraces, broken here and there by ravines and wooden knolls, every space gloriously clothed with vegetation, and the sky-line broken by long lines of palm trees—from the sea it reminded one of Lisbon, but its splendid luxuriance of vegetation gives it a character of its own.

---

[1] "The Voyage of the *Challenger*. The Atlantic: a Preliminary Account of the General Results of the Exploring Voyage of H.M.S. *Challenger* during the Year 1873 and the Early Part of the Year 1876." By Sir C. Wyville Thomson, Knt., LL.D., F.R.SS. L. and E., &c., Regius Professor of Natural History in the University of Edinburgh, and Director of the Civilian Scientific Staff of the *Challenger* Exploring Expedition. Two volumes. Published by Authority of the Lords Commissioners of the Admiralty. (London: Macmillan and Co., 1877.)

The scientific work of the *Challenger* was to be on the ocean, and Sir W. Thomson properly discouraged his staff from expending too much of their time or energies on investigating the natural history of the few spots of North or South America that they from time to time landed on. We therefore in these volumes meet with very few references to the glimpses that they got of this continent, but some time had to be spent at Bahia, and we cannot avoid giving the following interesting extract which describes a visit made by Sir W. Thomson to Santo Amaro.

"Mr. Wilson was obliged to be next day at Sto. Amaro, a little town about thirty miles distant, across one of the ridges on another river where he had a line of steamers plying, and he asked us to ride there with him; so we went back to his house and dined, and spent the evening at his window inhaling the soft flower-perfumed air and gazing at the stars twinkling in their crystal dome of the deepest blue, and their travesties in a galaxy of fire-flies glittering and dancing over the flowers in the garden beneath us. It was late when we tossed ourselves down to take a short sleep, for two o'clock was the hour fixed to be in the saddle in the morning. We rode out of the town in the starlight, Mr. Wilson, Capt. Maclear, and myself, with a native guide on a fast mule. We were now obliged to trust entirely to the instinct of our horses, for if a path were visible in the daylight there was certainly none in the dark, and we scrambled for a couple of hours right up the side of the ridge. When we reached the top we came out upon flat open ground with a little cultivation, bounded in front of us by the dark line of dense forest. The night was almost absolutely silent, only now and then a peculiar shrill cry of some night-bird reached us from the woods. As we got into the skirt of the forest the morning broke, but the *réveil* in a Brazilian forest is wonderfully different from the slow creeping on of the dawn of a summer morning at home, to the music of the thrushes answering one another's full rich notes from neighbouring thorn-trees. Suddenly a yellow light spreads upwards in the east, the stars quickly fade, and the dark fringes of the forest and the tall palms show out black against the yellow sky, and almost before one has time to observe the change the sun has risen straight and fierce, and the whole landscape is bathed in the full light of day. But the morning is for yet another hour cool and fresh, and the scene is indescribably beautiful. The woods, so absolutely silent and still before, break at once into noise and movement. Flocks of toucans flutter and scream on the tops of the highest forest trees hopelessly out of shot, the ear is pierced by the strange wild screeches of a little band of macaws which fly past you like the wrapped-up ghosts of the birds on some gaudy old brocade. There is no warbling, no song, only harsh noises, abrupt calls which those who haunt the forest soon learn to translate by two or three familiar words in Portuguese or English. Now and then a set of cries more varied and dissonant than

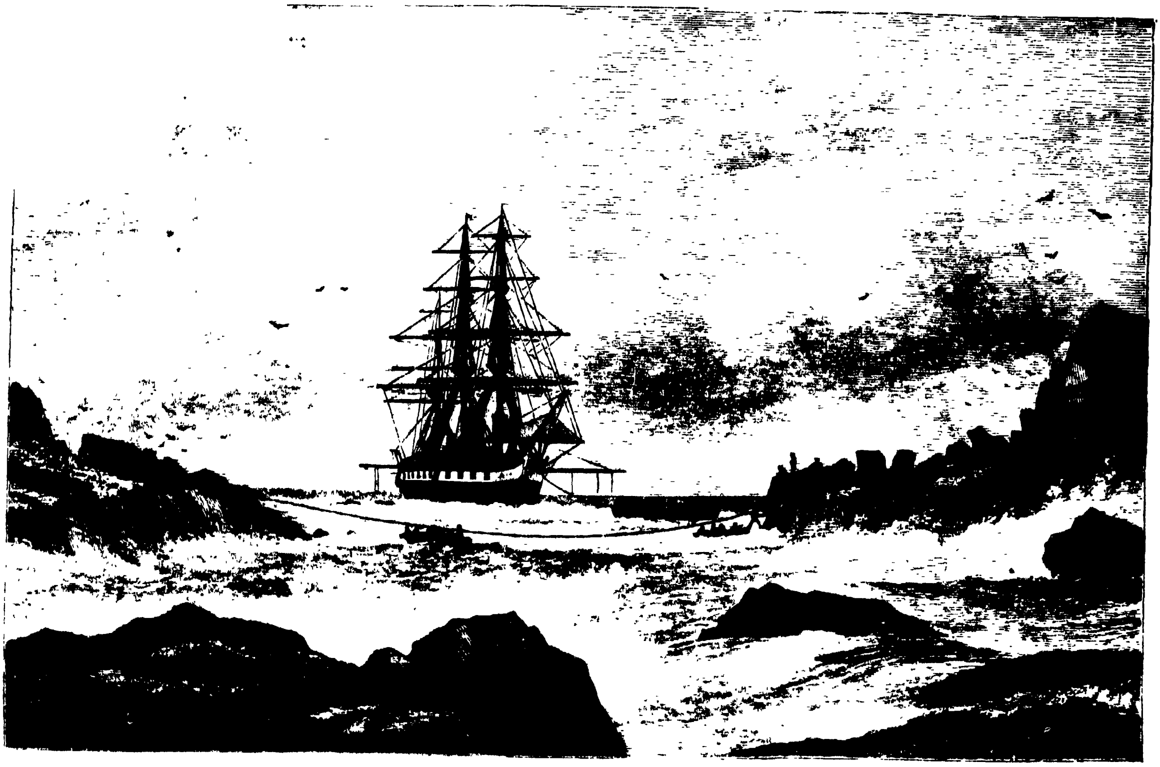

FIG. 1 The *Challenger* at St. Paul's Rocks

usual tell us that a troop of monkeys are passing across from tree to tree among the higher branches; and lower sounds to which one's attention is called by the guide indicate to his practised ear the neighbourhood of a sloth, or some other of the few mammals which inhabit the forests of Brazil. And the insects are now all awake, and add their various notes to swell the general din. A butterfly of the gorgeous genus *Morpho* comes fluttering along the path like a loosely-folded sheet of intensely blue tinsel, flashing brilliant reflections in the sun; great dark blue shining bees fly past with a loud hum; tree-bugs of a splendid metallic lustre, and in the most extraordinury harlequin colouring of scarlet and blue and yellow, cluster round a branch so thickly as to weigh it down, and make their presence perceptible yards off by their peculiar and sometimes not unpleasant odour; but how weak it is to say that that exquisitite little being, whirring and fluttering in the air over that branch of *Bignonia* bells, and sucking the nectar from them with its long curved bill, has a head of ruby, and a throat of emerald, and wings of sapphire—as if any triumph of the jeweller's art could ever vie in brilliancy with that sparkling epitome of life and light.

"It was broad day when we passed into the dense forest through which the greater part of the way now lay. The path which had been cut through the vegetation was just wide enough for use to ride in Indian file, and with some care to prevent our horses from bruising our legs against the tree-trunks, and we could not leave the path for a single foot on either side, the scrub was so thick, what with fallen tree-trunks, covered with epiphytes of all descriptions, and cycads, and arums, and great thorny spikes of *Bromelia*, and a dense undergrowth, principally of melastomads, many of them richly covered with blue and purple flowers. Above the undergrowth the tall forest trees ran up straight and branchless for thirty or forty feet, and when they began to branch, a second tier of vegetation spread over our heads, almost shutting out the sky. Great climbing *Monsteras* and other arals; and epiphytic bromeliads; and orchids, some of them distilling from their long trusses of lovely flowers a fragrance which was almost overpowering; and mazes of *Tillandsia* hanging down like tangled hanks of grey twine. Every available space between the trees was occupied by lianas twining together or running up singly, in size varying from a whipcord to a foot in diameter. These lianas were our chief danger, for they hung down in long loops from the trees and lay upon the ground, and were apt to entangle us and catch the horses' feet as we rode on. As time wore on it got very close and hot, and the forest relapsed into silence, most of the creatures retiring for their noonday siesta. The false roof of epiphytes and parasites kept off the glare of the sun, and it was only at intervals that a sheaf of vertical beams struck through a rift in the green canopy, and afforded us a passing glimpse of the tops of the forest trees, uniting in a delicate open tracery far above us.

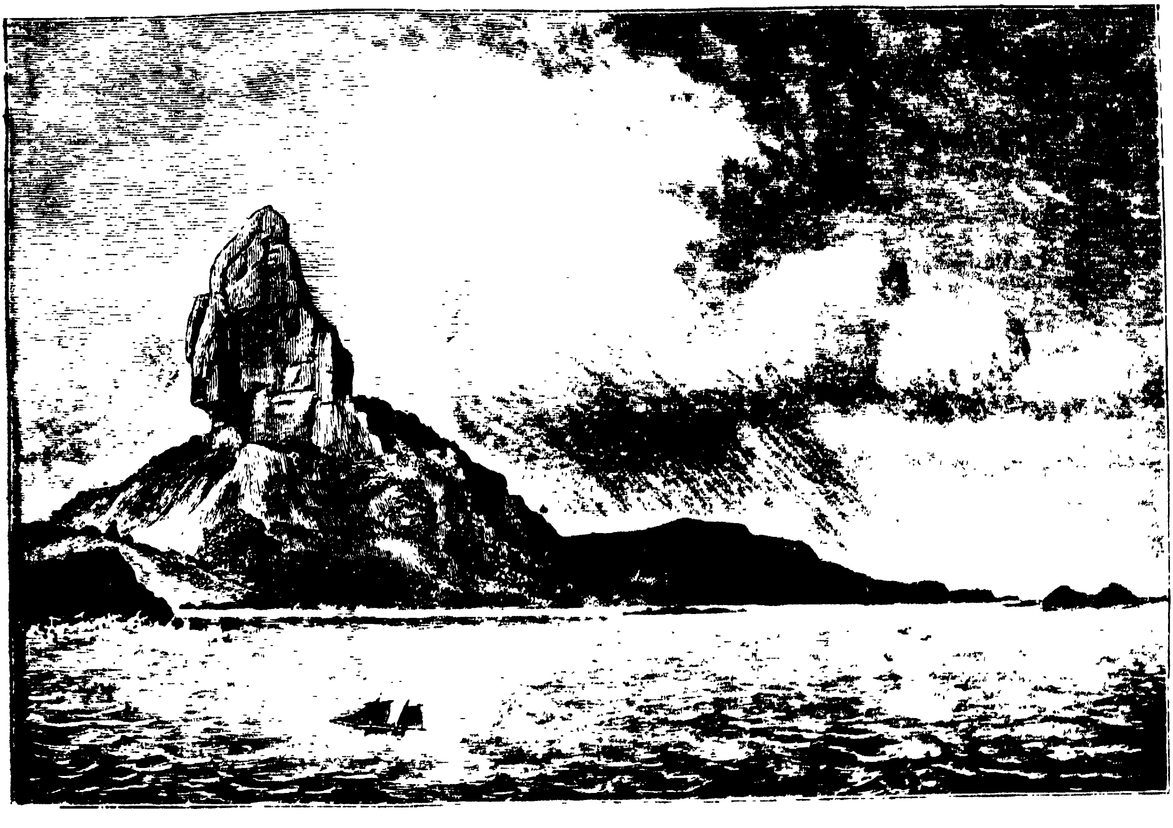

Fig. 2.—Fernando Noronha.

"For some hours our brave little horses struggled on, sometimes cantering a little where the path was pretty clear, and more usually picking their way carefully, and sometimes with all their care floundering into the mud-holes, imperfectly bridged over with trunks of trees.

"As we had made our ascent at first, all this time we had been riding nearly on a level on the plateau between the two river valleys. Suddenly the wood opened, and we rode up to the edge of a long irregular cliff bounding the valley of Sto. Amaro. The path ran right up to the edge and seemed to come to an end but for a kind of irregular crack full of loose stones which went zigzagging down to the bottom at an angle of about 70°, and we could see the path down below winding away in the distance towards the main road to Sto. Amaro. We looked over this cliff and told Mr. Wilson firmly that we would *not* go down the side of that wall on horseback. He laughed, and said that the horses would take us down well enough and that he had seen it done, but that it was perhaps a little too much; so we all dismounted, and put the horses' bridles round the backs of the saddles and led them to the top of the crack and whipped them up as they do performing horses in a circus. They looked over with a little apparent uneasiness, but I suspect they had made that precarious descent before, and they soon began to pick their way cautiously down one after the other, and in a few minutes we saw them waiting for us quietly at the bottom. We then scrambled down as best we might, and it was not till we had reached the bottom, using freely all the natural advantages which the *Primates* have over the *Solidunguli* under such circumstances, that we fully appreciated the feat which our horses had performed.

"The next part of the road was a trial; the horses were often up nearly to the girths in stiff clay, but we got through it somehow, and reached Sto. Amaro in time to catch the regular steamer to Bahia."

And here is an uncommonly good anecdote about a parrot:—

"At Sto. Amaro a line of tramways had lately been laid down also under the auspices of our enterprising friend, and we went down to the steamboat wharfs on one of the trucks on a kind of trial trip. The waggon went smoothly and well, but when a new system is started there is always a risk of accidents. As the truck ran quickly down the incline the swarthy young barbarians, attracted by the novelty, crowded round it, and suddenly the agonised cries of a child, followed by low moanings, rang out from under the wheels, and a jerk of the drag pulled the car up and nearly threw us out of our seats. We jumped out and looked nervously under the wheels to see what had happened, but there was no child there. The young barbarians looked at us vaguely and curiously, but not as if anything tragical had occurred, and we were just getting into the car again, feeling a little bewildered, when a great green parrot in a cage close beside us went through no doubt another of his best performances in the shape of a loud mocking laugh. A wave of relief passed over the party, but we were rather late, and the drivers expressed to the parrot their sense of his conduct, I fear strongly, but in terms which, being in Brazilian *patois*, I did not understand."

In another notice we will tell of the *Challenger's* doings between Bahia and Cape Town, and from the Falklands home, and we will also more particularly allude to the general results of the scientific work she has so successfully accomplished.

(*To be continued.*)

ON THE PRESENCE OF OXYGEN IN THE SUN

I HAVE spent the greater part of last winter and the beginning of this in an investigation of the spectra of oxygen. My experiments will be published, I hope, in another place; but there are one or two points of more immediate interest, and, I venture to think, of some importance, which I trust you will allow me to discuss in your columns.

Prof. Draper has lately announced the important discovery that the lines of oxygen are found to be present in the sun. These lines, however, are bright, and not dark, as the Fraunhofer lines. I had found that at a certain temperature, lower than that at which oxygen shows its well-known lines, it gives another spectrum, and it occurred to me, when I heard of Prof. Draper's discovery, that if the temperature of the sun, at some point intermediate between the photosphere and the reversing layer was the same as that at which the spectrum of oxygen changes, the fact that the *known* spectrum of oxygen appears bright would be fully explained. The spectrum of lower temperature, which, for reasons to be given, I shall call the compound line spectrum of oxygen, ought in that case to be found reversed in the solar spectrum, like the remainder of the Fraunhofer lines.

I have consequently devoted all my time during three weeks to the exact measurement of these four lines, and I do not think that the evidence which I am about to give will be considered to fall far short of an absolute proof that the spectrum is really reversed in the sun.

Two difficulties have put themselves into the way of exact measurement. The first is due to the extreme weakness of the spectrum. The light itself is not stronger than that of a non-luminous Bunsen burner; and after that light has passed through four prisms, as in most of my experiments, or through seven, as in some of them, there is not much of a spectrum left to be measured. It is only after having been in the dark for half-an-hour that the eye is able to do the work, and there are a good many days when the eye never obtains sufficient sensitiveness to make any trustworthy measurements. But whenever my eyes were in sufficiently good condition, my measurements agreed so well, that I have no hesitation in saying that they are as accurate as the measurements of the solar lines which will be found by their side. The second and more serious difficulty is due to the fact that the lines in question widen to a great extent with increased pressure and in such a way that the brightest part, and still more, the centre of the band, is displaced towards the red. I have not been able to get the lines perfectly sharp, and the measurement of the centre of the band will give, therefore, too high a value of the wave-length. The following table contains the numbers which I have obtained:—

Oxygen.	Width.	Solar Lines.	
		A.	S
α 6156·86	±0·3	6156·70	6156·60
β 5435·55	±0·3	5435·44	5435·56
γ 5329·41	±0·6	5329·3	5329·10
δ 4367·62		4367·58	

The first column contains the wave-length of the compound line spectrum of oxygen. The second column contains the number which has to be added or subtracted from the wave-length, in order to get the edge of the lines, as it is their centres which are given in the first column. The third and fourth columns give the wave-lengths of the corresponding solar lines as observed by Angström (A.) or myself (S.). The greatest difference is found in the line γ, but even this difference only amounts to the twentieth part of the distance between the sodium lines, and it would require a spectroscope of very good dispersive power and definition to separate two lines which would be that distance apart from each other. Nevertheless the amount in question is greater than the possible errors of observation, and I believe the difference to be due to the fact mentioned above, that the lines widen unequally. It will be seen from the table that the solar line would fall within the oxygen line, but about one-third of the distance between its most refrangible and least refrangible edge. At a higher pressure the brightest part of the band lies about 5331. None of the other lines widen nearly as much, and δ is always perfectly sharp. Angström gives it as an iron line, but according to Kirchhoff, the solar line is composed of two lines, and separated by a distance of about 0·1.

The average distance between the solar lines in the green, which have not yet been identified, is about 4·4, or more than fourteen times the difference between the centre of the oxygen line and the corresponding solar line. The average distance between the non-identified lines near O α is 4·9, or about twenty-nine times the corresponding difference. In judging, however, of the value of the evidence, I should like the reader to leave the line δ out of account. Although the agreement seems perfect, I have not the same confidence in the correctness of the wave-length as I have with the other lines. The line β is weaker than the others, and the error of observation may be a little larger than with α and γ, which will, I think, be found correct to the decimal place.

Let me point out in a few words the importance of the results obtained. The compound line spectrum of oxygen can only exist under a limited range of physical conditions. It is broken up at a higher temperature into the elementary line spectrum, and at a lower temperature it tumbles together into a continuous spectrum. During its existence its lines may be subject to variations owing to pressure. The spectrum of oxygen is therefore pre-eminently fitted to be at once the pressure gauge and thermometer of the sun. We cannot at the present moment give the exact temperature of the points at which the changes take place; but we can say with certainty why it is that the line spectra of many metalloids are not found reversed in the sun, for the temperature which gives these line spectra is higher than that which gives the compound line spectrum of oxygen, and therefore higher than that of the reversing layer of the sun. Consequently we must look for their band spectra and not for their line spectra. The same may be true for the spectra of some of the heavier elements like gold, silver, and platinum, which have not yet been discovered in the sun. The continuous spectrum of the base of the corona is most likely the continuous spectrum of the cooler oxygen.

As the science of spectroscopy advances we shall be able to determine the physical conditions which exist on the surface of the sun with as great a degree of certainty and a much smaller degree of discomfort than if we were placed there ourselves. I hope that this communication will prove to be a step in that direction. All my experiments were made in the Cavendish Laboratory.

ARTHUR SCHUSTER

St. John's College, Cambridge, November 30

OUR ASTRONOMICAL COLUMN

JUPITER'S SATELLITES.—Amongst the recorded phenomena connected with the motions of the satellites of Jupiter are several notices of observed occultations of one satellite by another, and of small stars by one or other of the satellites. The following cases may be mentioned:—On the night of November 1, 1693, Christoph Arnold, of Sommerfeld, near Leipsic, observed an occultation of the second satellite by the third at 10h. 47m. apparent time. On October 30, 1822, Luthmer, of Hanover, witnessed an occultation of the fourth satellite by the third at 6h. 55m. mean time.

Flaugergues, writing to Baron de Zach, from Viviers, on November 18, 1821, says: "I begin with an observation, very useless, no doubt, but extremely rare, for I have not found a similar one in the collections of astronomical observations which I have examined; *i.e.*, the occultation of a very small star by the third satellite of Jupiter." He proceeds to mention that on August 14, 1821, he repaired to his observatory very early to observe an eclipse of this satellite, and having looked at Jupiter with the telescope, he remarked a very small star near the third satellite. The satellite approached this star, and at 1h. 47m. sidereal time, it appeared to touch it, and at 1h. 56m. 52s. it was not possible to distinguish the star—it had disappeared. The satellite became fainter and disappeared in its turn at 1h. 59m. 10s. sidereal time, on August 13, or 16h. 30m. 8·5s. mean time at Viviers. The sky was perfectly clear, and Flaugergues considered his observations very exact. He adds that he continued to observe for a long time after the immersion of the satellite, hoping to see the star reappear, but he could not again distinguish it; the twilight had much increased, and small stars in the neighbourhood of Jupiter were soon effaced.

There is a similar observation by Mr. G. W. Hough, at Cincinnati Observatory, communicated in a letter to Dr. Brunnow, when Director of the Observatory at Ann Arbor, Michigan, and published in his "Astronomical Notices" Mr. Hough states that on March 28, 1860, he witnessed the end of an expected occultation of a star 9·5 mag., by Jupiter, and the occultation of the same star by the first satellite. When first seen it was distant from the limb of the planet about one diameter of the satellite, or one second of arc, so that the real separation had taken place about six minutes before (or about 8h. 9m. sidereal time), though he was not able to see it. At 10h. 27m. sidereal time the star was occulted by the first satellite and remained invisible eight minutes. Mr. Hough further says that the star is found in the "Redhill Catalogue," an obvious oversight; it would appear to be No. 1630 of Zone + 22° in the *Durchmusterung*, a star of 9·3m. the approximate place of which for 1855 was in R.A. 7h. 8m. 5s., N.P.D. 67° 3′·3.

DONATI'S COMET OF 1858.—This comet which attained so great a celebrity in the autumn of 1858, makes a very close approximation to the orbit of Venus near the descending node, and it may be reasonably inferred that the actual form of its path round the sun may be due to a very near approach of the two bodies at some distant epoch. The discussion of the totality of observations was undertaken some years since by Dr. von Asten, who has published his results in a dissertation entitled "Determinatio orbitæ grandis cometæ anni 1858, e cunctis observationibus." The comet was discovered by Donati on June 2, and was observed until the beginning of March, 1859, at the Cape of Good Hope and at Santiago de Chile; consequently the observations extended over a very wide arc of the orbit, and there have been very few cases where careful discussion could be expected to lead to more reliable results. The period of revolution deduced by Dr. von Asten is 1,880 years, and there is a high probability that this does not differ materially from the true one, applying to the time of the comet's appearance. Prof. Hill, of Washington, also by a complete investigation, obtained a somewhat longer period, but the general character of the orbit remains the same. Employing Dr. von Asten's elements, it will be found that in heliocentric longitude 343°·7, the distance of the comet from the orbit of Venus, is only 0·0047 of the mean distance of the earth from the sun. In 1858 the two bodies came into pretty near proximity, their mutual distance on October 17 being 0·088. It has been mentioned above that the point of closest approach of the orbits of the planet and comet is situated near the descending node; the opposite node falls in the region of the minor planets.

THE OBSERVATORY OF LYONS.—The *Bulletin Hebdomadaire* of the French Scientific Association reports that M. André is actively employed in the establishment of this new astronomical institution and is energetically supported by the Government. M. Raphël Bischoffsheim, the munificent donor of the meridian circle, lately mounted at the Observatory of Paris, has also intimated his intention to present the Lyons Observatory with its fundamental instrument, a meridian-circle of dimensions but slightly inferior to those of the circle, for which the Observatory at Paris is indebted to him. It will also be constructed by Eichens. The Paris meridian-circle is intended to replace the instruments of Gambey, which are now placed in one of the saloons of the institution with other instruments which have seen their day. M. Wolf remarks that the scientific zeal and liberality of M. Bischoffsheim "inaugurates in France a path long followed in England by wealthy amateurs of astronomy."

THE METEORITE OF JUNE 14, 1877.—M. Gruey has calculated the orbit of this meteorite with the assistance of the Observatory of the Puy-de-Dôme, and accounts obtained through the press of Clermont, where he observed it at 8h. 55m. P.M. local time. Observations made at Bordeaux and at Angoulême were combined with those at Clermont. He obtained for the velocity of the meteor relatively to the sun 93 kilometres in a second, in the direction – heliocentric longitude 15° 17′, latitude – 17° 3′, and neglecting the insignificant effect of the earth's attraction upon a velocity so great, and the unknown effect of atmospheric resistance, he found for the heliocentric motion of the meteor the following elements of a hyperbolic orbit. Eccentricity, 7·079, semi-axis, 0·137. Ascending node, 83° 49′, inclination, 18° 14′, perihelion from node, 286° 50′, longitude at appearance, 263° 49′; the meteor approaching its perihelion was thus distant 23° from it.

This adds another case to several previous ones in which hyperbolic orbits have been obtained for meteorites by Petit, Galle, Tissot, &c.

PROF. NEWCOMB.—At the meeting of the Royal Society on Thursday last, the distinguished mathematical astronomer, Prof. Simon Newcomb, of Washington, was elected one of its foreign members. There was previously on the list only a single American, viz., Prof. Asa Gray. Prof. Newcomb's important contributions to astronomical science will be admitted to have richly entitled him to an acknowledgment at the hands of our leading society.

CHEMICAL NOTES

MINERAL OIL IN A LAVA OF MOUNT ETNA.—In the basaltic zone which reaches from the foot of Mount Etna in a south-south-easterly direction, near the village of Paterno there is a prehistoric doleritic lava containing olivine, which surrounds the clay deposits of a mud volcano and which has been examined by Sig. Orazio Silvestri. Under the microscope the lava shows an augitic principal mass with a quantity of olivine and many white transparent crystals of labradorite. The lava contains numerous round or irregular cavities which are coated with arragonite and which are filled with mineral oil. This oil, of which there is about 1 per cent. by weight in the whole mass, was taken from one of the cavities at 24° C. At about 17° C. it begins to solidify and is of a yellowish green tint by transmitted light, while by reflected light it is opalescent and light green. Chemical analysis of the liquid proved it to contain :—

Liquid hydrocarbons (boiling point 79°·28) ...	17·97 per cent.
Hydrocarbons solidifying under 0° (b. p. 280°–400°)	31·95 „ „
Paraffine, melting point 52°–57°	42·79 „ „
Asphalt (leaving 12 per cent. of ashes) ...	2·90 „ „
Sulphur	4·32 „ „
	99·93

FORMATION OF CERTAIN BODIES AT TEMPERATURES ABOVE THAT OF THEIR DECOMPOSITION.—MM. Troost and Hautefeuille have lately demonstrated that under certain circumstances it is incorrect to suppose that bodies undergoing decomposition or rather dissociation at a low temperature may not exist as definite compounds at higher temperatures. Their arguments are founded on the decomposition of silicon sesquichloride (Si_2Cl_6) at 800°, which may be represented as—

$$2Si_2Cl_6 = 3SiCl_4 + Si,$$

if, however, the reaction be carried on at a temperature above 1200° the following change takes place—

$$3SiCl_4 + Si \quad 2Si_2Cl_6.$$

If the tube in which this reaction takes place be cooled suddenly the sesquichloride is found, but if cooled slowly it undergoes gradual decomposition. They also find that although ozone is converted into oxygen at 250°, if a silver tube inclosed in a porcelain tube be kept at about 1300° a deposit of dioxide of silver is produced due to the formation of ozone. They state that the ozone can be recognised by the usual tests if the gas be rapidly drawn off and quickly cooled. They have also examined certain similar phenomena in the production of oxide of silver at 1400°.

IODATES OF COBALT AND NICKEL.—Prof. F. W. Clarke describes these salts, which were prepared by dissolving the carbonates in aqueous iodic acid, and allowing the solution to evaporate spontaneously when salts of the composition $CoI_2O_6.6H_2O$ and $NiI_2O_6.6H_2O$ crystallise out. If the solution of the carbonate of cobalt in iodic acid is evaporated rapidly, then the iodate of Rammelsberg, containing 1½ molecules of water may be obtained, but not otherwise. The cobalt iodate loses four molecules of water at 100°, but the remaining two molecules cannot be driven off without partial decomposition of the salt. The specific gravities of the two salts are almost identical, the cobalt iodate at 21° being 3·6893, the nickel iodate at 22° being 3·6954. No numbers of the solubilities of the two salts are given by Prof. Clarke, but these, when obtained, will be of some interest.

ORIGIN AND FORMATION OF BORACIC ACID.—M. Dieulafait (*Comp. Rend.* lxxxv. 605) finds that under certain conditions by spectrum analysis $\frac{25}{10000000}$ grammes of boron, and by the colour imparted to a hydrogen flame $\frac{1}{10000000}$ grammes may be detected. He considers boracic acid to be a normal constituent of sea-water and salt marshes lying above beds of carnallite. M. Dieulafait finds that this acid may be recognised in a drop of sea-water weighing about 0·0378 grammes, and that the minimum quantity found in the Mediterranean is two decigrammes per cubic metre of water. He arrives by geological reasoning at conclusions differing from those of Dumas and others with regard to the origin of this body in the lagoons of Tuscany, and thinks that the source of boracic acid in this district may be found in a relatively modern formation.

NEW MODES OF FORMING ETHYLEN OXIDE.—In the *Comptes Rendus*, lxxxv. 624, Mr. H. Greene mentions the results of experiments on the action of certain metallic oxides on the bromide, iodide, and chloriodide of ethylene. Oxide of silver has a rapid action on ethylen iodide at a temperature of 150°, forming ethylen oxide; its action on ethylen bromide produces the same result but requires a higher temperature. Ethylen bromide and chloriodide both act upon sodium oxide at 180°, the latter of the ethylene compounds being the one found most advantageous by the author in preparing ethylen oxide. He has also studied the action of these substances on the oxides of the diatomic metals barium and lead. These oxides do not give ethylen oxide when heated with bromide or chloriodide of ethylene. These experiments show, on the one hand, the analogy between the silver and sodium oxides confirmed by the isomorphism of their anhydrous sulphates and chlorides, and on the other their difference from the group of diatomic oxides.

THE ACTION OF CERTAIN ANTISEPTIC VAPOURS ON THE RIPENING OF FRUITS.—MM. Lechartier and Bellamy give an account in the *Comptes Rendus*, lxxxiv. 1,035, of some experiments they made on the fermentation of apples when inclosed in vapours such as carbolic acid, camphor, and potassium cyanide. From their results it appears that no fermenting action took place in the apples surrounded by vapour of carbolic or hydrocyanic acids, and a slight action only in the one surrounded by camphor vapour. The camphor vapour, in f[illegible], diminishes without entirely destroying the vitality of the cells. In this journal, also, there is an account of experiments performed in the same direction by M. Gayon. He incloses the apples in vapours of chloroform, ether, and carbon disulphide, and his results agree with those of the first observers. The chloroform and ether act in the same manner as the carbolic and hydrocyanic acids; the carbon disulphide in the same way as camphor, permitting partial fermentation only.

A Problem in Chemical Affinity.—In his work on "Gasometric Methods," Prof. Bunsen details an interesting series of experiments on the phenomena accompanying the explosion of hydrogen and carbon monoxide with a volume of oxygen insufficient for its complete combustion. From the results he deduces the conclusion that the ratio between the products of combustion ($H_2O : CO_2$) can always be expressed by *small whole* numbers (1 : 2, 1 : 3, 1 : 4, &c., and that it alters suddenly from one figure to the next by gradually increasing the amount of hydrogen. Deeming the nine experiments upon which the conclusion was based as insufficient for the establishment of a general principle, Prof. Horstmann, of Heidelberg, describes in the *Verhandlungen des heidelb. naturf. med. Vereins*, an extensive series of observations designed to test the truth of the law. Among his results the following facts are of interest. In exploding CO with gradually increasing quantities of $H_2 + O$, while the ratio between H and CO increased from 0·25 : 1 to 2·33 : 1, the ratio between H_2O and CO_2 gradually increased from 0·8 : 1 to 4·5 : 1, with no evidence of a predilection for rational numbers. Experiments on a mixture of CO and H, with gradually increasing amounts of O, led to the same results, showing no such regularity in the division of O between the two combustible gases as Bunsen's law would indicate. When aqueous vapour is present in the mixture less H and more CO unites with O, while the presence of CO_2 reverses the case. By gradually increasing the amount of O in the explosive mixture, it was noticed that the ratio between the resultant H_2O and CO_2 increased until it attained a maximum, when 35 per cent. of the combustible gases were oxidised, and then sank regularly to the ratio denoting complete combustion. The oxygen appears to be divided among the two gases according to the following law:—The ratio between the resultant H_2O and CO_2 is equal to the ratio between the residual H and CO multiplied by a co-efficient of affinity which is independent of the ratio between the combustible gases but dependent on the relative quantity of O present. This co-efficient of affinity varied between 4 and 6·4, showing that always more H relatively than CO is consumed, and hence that the affinity of O to H is greater than that to CO.

Halogen Derivatives of Amines.—An attempt has frequently been made by chemists to replace the hydrogen in the hydrocarbon group present in amines, by Cl, Br, or I. These efforts have hitherto resulted simply in the substitution of the basic H atoms of the amine by halogens—as $C_2H_5.NCl_2$—or in complete decomposition. A. Michael (*Berl. Ber.*, x., 1644) has devised a method for accomplishing this end, which consists in first replacing these basic H atoms by acid residues, and then exposing to the action of a halogen ethyl-phthalimide,

$$C_6H_4(CO)_2N.C_2H_5,$$

yields in this way with Br a tribromo-ethyl-phthalimide.

Double Salts with Cyanide of Gold.—C. G. Lindbom publishes in the *Univ. Arsskrift* of Lund an exhaustive account of these compounds, which may be regarded as salts of the two acids, HCy.CyAu and $HCy.CyAu.Cy_2 + 1\frac{1}{2}aq.$, neither of which, however, can be obtained pure for analysis on account of their tendency to decompose. Most of the auro salts unite directly with a molecule of the halogens; for example aurocyanide of sodium, $NaCy_2Au$, forms bromo-auricyanide of sodium, $NaCy_2AuBr_2+2aq.$ Aurocyanide of ammonium, $AmCy_2Au$, is decomposed at 100°.

The Fourth Nitrobenzoic Acid.—Prof. F. Fittica has discovered lately a new nitro-benzoic acid, making the fourth of the isomeric acids, which has been contested by other chemists, especially as it fails altogether to harmonise with the theories at present accepted in regard to the structure of benzene derivatives. In the October session of the Deutsche chemische Gesellschaft, he strengthens his position by announcing the discovery of a fourth nitro-benzaldehyde, obtained by the action of H_2SO_4 on benzaldehyde and ethylic nitrate, which on oxidation is changed into the new nitrobenzoic acid, $C_6H_4 NO_2.COOH$.

Influence of Isomerism on the Formation of Ethers between Acids and Alcohols.—In the September session of the Russian Chemical Society, Prof. H. N. Menschutkin presented an elaborate paper on this subject based on observations of the formation of acetic ethers. The process consisted in inclosing molecular weights of an alcohol and acetic acid in glass tubes, immersing it in a glycerine bath at 154° for a certain time, and then rapidly cooling it, and titrating the unaffected acetic acid with baryta water. The results show that in regard to the rapidity and limits of etherification, the primary alcohols are sharply divided from the secondary, and the latter from the tertiary; and the saturated alcohols from the non-saturated. A regular decrease in the rapidity coincides with an increase in the molecular weight of the alcohol. As in many other series of experiments, methylic alcohol shows considerable deviations from the laws governing its higher homologues. In the case of non-saturated alcohols the rapidity is less than that of the corresponding primary alcohols, but greater than that of the corresponding secondary alcohols.

Phosphides of Tin.—Since the introduction of phosphorus bronze, the compounds of phosphorus and the metals are receiving more attention. S. Natanson and G. Vortmenn describe (*Berl.*, *Ber.*, x. 1459), several methods of preparing phosphides of tin, viz., throwing P on molten tin, melting a mixture of vitreous phosphoric acid, charcoal, and tin, and passing phosphorus vapours over molten tin in a hydrogen stream. These processes all yield a crystalline silvery white compound, containing from $1\frac{1}{2}$ to 3 per cent. of P, and leaving on treatment with HKO a residue of pure SnP.

Chemical Action of Light.—In a late number of the *Annales de Chimie et Physique*, M. Chastaing advances, in connection with a variety of observations on this topic, the theory that the chemical action of the various coloured rays on inorganic substances is dependent on refrangibility, blue and violet acting as reducing agents, red and yellow causing oxidation. Prof. H. W. Vogel attacks this opinion vigorously in the last session of the German Chemical Society, claiming that the nature of the substance causes the action to be one of reduction or oxidation. The union of H and Cl, which takes place so rapidly in violet light, is regarded as purely analogous to oxidation, and he alludes to Timiriazeff's late experiments, showing that the reduction of CO_2 by plants, proceeds more rapidly in red light than in green.

NOTES

At the meeting of the Royal Society, on Thursday last, the *Times* states, the following were elected foreign members:—Marcellin Berthelot, of Paris; Joseph Decaisne, of Paris; Emil Dubois Reymond, of Berlin; Adolph Wilhelm Hermann Kolbe, of Leipsic; Rudolph Leuckart, of Leipsic; Simon Newcomb, of Washington; and Pafnutij Tschebytschow, of St. Petersburg. By this election the foreign list of the society is made up to its full complement of fifty members.

Mr. Alexander Agassiz, it is understood, proposes to spend the winter in the prosecution of scientific research in the Florida

MM. **Feil** and **Fremy**, at last week's meeting of the Paris Academy of Sciences, read a paper describing a new process for the manufacture of rubies and other precious stones. The sensation created by these wonderful experiments has been so general that the Association of Jewellers have written to some of the papers stating that it was impossible for human art to compete against nature, that mysterious maker having at her disposal an indefinite number of centuries, which is not the case with any human worker. M. Daubrée, the Director of the School of Mines, has expressed the wish to open, in the public museum of that magnificent establishment, a gallery for the exhibition of minerals produced artificially. M. Feil has already produced in his glass foundry, and by the same process as rubies, an immense number of stones which can be compared with the most admirable crystalline productions of nature. Some of them are so inexpensive that they may be used for ordinary decorative purposes.

An extraordinary but happily unsuccessful attempt was recently made upon the life of Mr. Russell, the Government Astronomer at Sydney, New South Wales. On September 8 a lad of about nineteen years of age left a box at the observatory for Mr. Russell, who, under the impression that it contained instruments of some kind, proceeded to open it. He found the lid a sliding one, similar to those adapted to ordinary instrument cases, and he had not drawn it far when he discovered that the affair partook more of the character of an infernal machine than anything else. The movement of the lid became rather stiff, and upon inspecting it and the box a little more closely he discovered at one end of the latter several grains of powder. The box was then taken into the open air, where it was investigated with special care. The lid was released, and there were found in the box at least 4½ lbs. of blasting-powder. In it were no less than sixteen matches, stuck with their sulphurous points in dangerous proximity to a sheet of sand-paper fastened to the under-side of the

considerations.

The enlarged council of the Paris Observatory held last Saturday a very interesting meeting. M. Faye has not resumed his seat as councillor. Several reclamations were read against the resolutions which had been adopted in the previous sitting. One of them was on behalf of the Bureau des Longitudes, asking to be allowed to have a voice in the presentation of the Director of the Observatory, as well as the Council and the Academy of Sciences. From the foundation of the Bureau des Longitudes up to 1854, when M. Leverrier was appointed director for life by Napoleon III., the Bureau des Longitudes had the control of the observatory. Each year the Bureau appointed one of its members to superintend the observations, and the custom was to reappoint the same member up to his death. Arago thus held his office by yearly tenure for more than a quarter of a century. The discussion of meteorological matters was begun, and the meeting adjourned till to-day. No formal proposition will be made to sever the International Bureau from the Observatory, the aim of certain members being confined to the establishment of a Central Board for Meteorology, which will give its advice on the organisation of the International Bureau, the Montsouris Central Observatory, the Puy de Dôme, the Pic du Midi, and any other establishment which may be founded for meteorological purposes.

We are happy to state that the rumour widely spread in Paris of the death of Drouyn de Lhuys is unfounded, the learned gentleman having recovered, against almost all hopes. He will very likely resume his place in the several scientific societies which he had resigned.

M. **Milne Edwards** has been appointed president of the French Scientific Association, which was founded by M. Lev[illegible]er thirteen years ago. Under the direction of M. Leverrier the association spent not less than 250,000 francs for scientific purposes, and has accumulated a sum of about 400,000 francs. The association is supported solely by voluntary contributions, and meets yearly at Paris. Many improvements are contemplated by the new president.

A CHIMPANZEE, about 2½ years old, has been recently placed on view at the Westminster Aquarium by Mr. Farini. It is very gentle in disposition, and is undergoing an education in the usages of civilised life at the hands of its keeper, Mr. Zack Coup. For some time it has been in one of the private houses at the Zoological Gardens, and there it caught cold. On its removal to the room at the Aquarium, where a temperature of about 70° is maintained, it improved, but the fog of yesterday (Wednesday) seemed to oppress it very much. It is suffering both in head and lungs, though it still struggles very successfully to be cheerful and entertaining. It is curious that Pongo's lungs were found all sound, though the few chimpanzees that have been exhibited in Europe have succumbed to lung disease. With the chimpanzee are also a very fine cynocephalus, a "sacred" monkey from India, and a number of monkeys less rare. There are close by a python, a boa, and two anacondas, and in order to insure that they hall not be hidden in rugs when visitors want to see them, they are at intervals exhibited by an Abyssinian girl, who goes through the ceremony of an incantation each time.

IN his introductory address at the opening meeting of the Royal Society of Edinburgh Sir Alexander Grant stated that the society was an emanation from the University of Edinburgh, from which it sprang on the suggestion of Principal Robertson in the latter part of 1782. Thus, in the same year that the University would celebrate its tercentenary the society would be able, perhaps conjointly, to celebrate its 100th birthday. In one essential particular it differed from the Royal Society of London. From the first the promotion of literature as well as science was the object of the Royal Society of Edinburgh. But it had been observed that the literary element in their proceedings had been gradually dwindling away. Sir Alexander had inquired as to the number of papers not connected with philosophical science which had been contributed during the last fifteen years, and it appeared to be considerably less than forty, or little more than two per annum. In the last fifteen years, out of about 370 ordinary Fellows of the Society, only about twenty had come forward to contribute papers other than philosophical or mathematical. The Council of the Society have awarded the Macdougall-Brisbane prize, consisting of a gold medal and 15*l.* 14*s.* 7*d.*, to Mr. Alex. Buchan, for his paper on "The Diurnal Oscillations of the Barometer." Prof. Balfour reported that the membership of the Society at present was 427, consisting of 373 ordinary and fifty-four honorary or non-resident Fellows.

ADVICES from the Howgate Arctic Expedition have been received up to the date of October 2, at which time the vessel had reached Niantitik Harbour, in Cumberland Gulf. The passage of forty-three days from New London had been very stormy, but, as far as reported, without any disaster. Mr. L. Kumlien, the naturalist of the party, had gathered some specimens, but did not find the promise of suitable collecting ground in the immediate vicinity very good. He hoped, however, to change his quarters to a better location.

WE learn from the *Isvestia* of the Russian Geographical Society, that at the beginning of September M. Prshevalsky had already started for Tibet. He is accompanied by an aid, M. Ecklon, four cossacks, and two soldiers. Having arrived at the conclusion that it will be impossible to reach Tibet by way of Lake Lob-Nor, he will try the route through Guchen and Hami, and thence to Zaidam and the upper parts of the Blue River. He expects to be at Lassa next year, about May or June, and if he succeeds, he will remain in Tibet for a year.

AFTER having penetrated last year for 160 miles up the Amu Daria, the Russian steamer *Samarkand* has penetrated this year as far as the fortified town Chardjui. A complete survey of the river was made, and considerable botanical and zoological collections were brought back by the officers on board.

RUSSIAN newspapers announce that the *Morning Dawn* reached St. Petersburg on December 1, having left the mouth of the Yenissei on August 21. This ship, or rather boat, 56 feet long, 14 feet wide, and drawing only 6 feet water, was built for the transport of wares up the Yenissei from Kureïka. It was never intended to go to sea, and "never," Prof. Nordenskjöld says, "so wretched a boat dared to enter the waters of the Arctic Ocean." Nevertheless Capt. Swanenberg, with a crew of four men, safely crossed on board this boat the Kara Sea, and reached the Russian capital after a hundred days' cruise. With a compass almost useless because of the deviation occasioned by the iron on board, and struggling with ice, he reached, on August 30, the Kara strait, where he experienced a heavy gale. On September 11 he was at Vardö. Thence, after a fortnight's stay, the *Morning Dawn* went in tow of a Norwegian steamer to Christiania, and further, in the same manner, to Göteborg, which was reached on November 3, and to Helsingfors, and finally to St. Petersburg The reception the gallant crew met with in the Norwegian towns was everywhere the most enthusiastic.

AT the last meeting, December 7, of the Russian Geographical Society, Col. Tillo read a report on the magnetical measurements made by M. Smirnoff in Russia. These measurements, accomplished with the utmost accuracy, embrace no less than 548 places, the declinations and inclinations having been measured at 287 places, and the former alone at 261. At the same meeting the Society resolved to enter into relations with different governments in reference to the establishment of polar meteorological stations, and to submit an elaborate scheme in connection with that subject to the next International Meteorological Congress.

GERMANY is still waging war against the illegal use of the doctor's title. A "Dr." Harmuth in Berlin who received his diploma from Philadelphia, was lately sentenced to pay 300 marks for using the prefix publicly.

M. POLYAKOFF, who was sent by the St. Petersburg Academy of Sciences for the exploration of the mammoth remains in the Government of Tomsk, has now returned to St. Petersburg after having made a journey in the Western Altai, the Kirghiz Steppe, and in the Seven Rivers' Province, where he visited the lakes Alakul and Balkash. He brings back very rich collections of animals and plants, and the results of his varied observations will appear in the *Memoirs* of the Academy.

THE scheme for telegraphing without wires, the *New York Tribune* states, by means of aërial currents of electricity, has been revived by Prof. Loomis. He has met with success in using kites for this purpose, a copper wire being substituted for the usual kite string. Signals were transmitted thus between kites ten miles apart. His new experiments are made in the mountainous regions of West Virginia, between lofty peaks. Continuous aërial currents are found at these altitudes, which will serve the purposes of the telegraph, except when rarely interrupted by violent disturbances of the atmosphere. A scheme is now on foot to test the merits of aërial telegraphy in the Alps.

THE *Journal of Forestry*, which started in the month of May last, in the interest of forest conservancy and management generally, maintains the reputation which the early numbers indicated. In recent numbers, Prof. Boulger, F.L.S., has contributed some papers, which are being continued, on "Cultural First Principles," in which he considers (1) "climate," (2) the "nature of the soil," and (3), "theoretical considerations (as to the treatment of the soil." In this latter portion of the subject drainage forms of course no inconsiderable part. Sloping plantations, it is shown, will seldom require artificial drainage, for such a situation on high soils is quite suited for conifers, and if on heavy soils sufficient for oak and other hard-wooded trees. Mr. Boulger points out, what ought to be apparent to all, that the growth of rushes, the wood rush (*Luzula*), the bog asphodel (*Narthecium*), a yellow star-like plant, the tufted hair-grass (*Aira cæspitosa*), or of mosses on the surface, are sure indications of the absolute necessity of drainage. Though these are facts with which a practical forester is well acquainted, it is nevertheless necessary to impress them upon the minds of all interested in forest produce. Some useful hints as to the preservation of timber for fencing, or in damp underground situations, are given in the number of the *Journal* for the current month.

R. Pictet describes some interesting experiments (*Arch. Sc. Phys.*, lix.) made for the purpose of determining the conditions under which transparent or non-transparent ice is formed. It was ascertained that water frozen in a vessel dipped in a cold glycerine solution formed perfectly transparent ice as long as the temperature ranged between 0° and – 1·5°. If the solution was cooled below – 3°, the ice was whitish and of a less specific gravity, these properties being intensified with the lowering of the temperature. No difference in the melting-point or amount of warmth required for melting was observable among the various varieties of ice. The opacity of ice results from an irregular arrangement of the ice-crystals, as well as from the presence of small bubbles of air—less than ½ mm. in diameter—which are mechanically inclosed. They can be removed by slowly conducting through freezing water large bubbles of air which carry with them the small bubbles.

At a public meeting held in the Cheltenham Masonic Hall on December 15, Sir F. Abbott in the chair, it was resolved to institute a "Cheltenham Philosophic Society," which should hold its meetings during the winter months. Upwards of fifty gentlemen signified their desire to become members, and a committee was formed to draw up rules to be submitted at a future date to a general meeting for their sanction.

Dr. John Rae asks us to state that in his paper on Eskimo skulls read at the Anthropological Institute on May 8 last, and published in the newly-issued number of the *Journal* of the Institute, he by mistake called the Western Eskimo Brachycephalic, whereas they are Mesocephalic.

In the letter on the meteor last week, p. 124, "8 (± 2) χ Lyræ," should be 8 (± 2) times Lyræ.

The additions to the Zoological Society's Gardens during the past week include a pair of Musk Deer (*Moschus moschiferus*), from Central Asia, presented by Sir Richard Pollock; a pair of Axis Deer (*Cervus axis*), from India, presented by Dr. Carl Siemens; a Diana Monkey (*Cercopithecus diana*), from West Africa, presented by Mr. P. Spink; a Bonnet Monkey (*Macacus radiatus*), from India, presented by Mr. T. H. Evans; a Patas Monkey (*Cercopithecus ruber*), from West Africa, a Red-backed Saki (*Pithecia chiropotes*), a Red-faced Spider Monkey (*Ateles paniscus*), two Kinkajous (*Cercoleptes caudivolvulus*), a Coati (*Nasua nasica*), an Azara's Fox (*Canis azaræ*), a Black Vulture (*Cathartes atratus*), from South America, deposited two Schlegel's Doves (*Chalcopelia puella*), from West Africa, two Lesser Razor-billed Curassows (*Mitua tormentosa*), from South America; two Waxwings (*Ampelis garrulus*), four Bullfinches (*Pyrrhula rubicilla*), European, purchased; four Common Waxbills (*Estrelda cinerea*), two Cinereous Waxbills (*Estrelda cærulescens*), six Orange-cheeked Waxbills (*Estrelda melpoda*), two African Silver Bills (*Munia cantans*) seven Yellow-rumped Seed Eaters (*Crithagra chrysopyga*), from West Africa. received in exchange; a Chinchilla (*Chinchilla lanigera*), born in the Gardens.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

Cambridge.—The Syndicate, appointed in May, 1875, to consider the requirements of the university in different departments of study, have just issued their fourth report on the subject. After stating that in their opinion the inter-collegiate system should be further stimulated and supplemented by the institution of university readerships, and that by a more complete organisation the requisite provision for teaching and the encouragement of research might be to a considerable extent made, they nevertheless are of opinion that certain subjects of great importance are not now represented in the professoriate, the absence of which from such representation constitutes a serious defect in the Cambridge system, and they recommend that professorships amongst other subjects should be created as soon as the resources of the university permit, in comparative philology, mental philosophy and logic, physiology, English language and literature.

The Syndicate, with regard to existing professorships, suggest that the Professorship of Mineralogy should be for the future a Professorship of Mineralogy and Mineral Chemistry.

There are other subjects of scarcely less importance of which there ought always to be recognised teachers in the University, although the Syndicate are not prepared to say that the teacher ought always to have the status of a professor. Such are analytical chemistry, morphological and physiological botany (as distinguished from systematic botany), comparative anatomy (as distinguished from zoology), pathological anatomy.

In other subjects, again, it is desirable that the University, without establishing permanent offices, should have the means of appointing professors or other teachers from time to time when there is the opportunity of securing the services of a specially competent person. Such are the theory and history of education, as also some special departments of natural science.

The following is the Natural Science Tripos' list for this year:—Class I.—(2) Ds. Bower, Trinity; (4) Cullen, Christ's; (1) Fenton, Christ's; (1) Greaves, Christ's; (2 and 3) Hill, Downing; (1) Ohm, Emmanuel; (3) Sedgwick, Trinity. Class II.—Ds. Harrison, Christ's; Holthouse, Trinity; Houghton, St. John's; Murton, St. John's; North, Sidney; Taylor, E. F. Vinter, Sidney. Class III.—Ds. Allen, St. John's; Buckmaster, Downing; Foster, Trinity; Wallis, St. John's; Weldon, Caius. The numbers indicate the subjects for knowledge of which the candidates are placed in the first class as follows:—1. Physics, chemistry, and mineralogy. 2. Botany. 3. Zoology and comparative anatomy, human anatomy, and physiology. 4. Geology.

Edinburgh.—The second meeting of the session of the Edinburgh University Chemical Society, was held on the 12th instant, John Gibson, Ph.D., F.R.S.E., vice-president, in the chair. J. S. Thomson communicated a paper on solutions of litmus, in which he explained the preservation of the colour of such solutions on exposure to the air by the action of the air preventing fermentation. He also read a paper on the Determination of Melting Points.

Technical University.—It may be remembered that a Committee of the City Companies has been for some time at work elaborating a scheme for founding a technical university in London. The last step taken by the Committee was to procure reports and suggestions from six specially nominated referees, viz., Prof. Huxley, Col. Donnelly (of the Science and Art Department), Capt. Douglas Galton, Mr. H. T. Wood (Assistant-Secretary of the Society of Arts), and Mr. Bartley (of the Science and Art Department). After having decided on these names, the Committee adjourned to allow time for the preparation of the reports. On Thursday last week they met again, and the reports were laid before them. After some discussion the further consideration of the subject was adjourned till January 17.

Taunton College School.—The Science Scholarship at Keble College, Oxford, is awarded to Mr. R. G. Durrant, of the Taunton College School. This is the fourth brilliant success that the school has gained in the last five months, and it is probably the last. The able science master, Mr. Shenstone, leaves at Christmas to take a Science Mastership at the revived Exeter Grammar School. He will not be replaced at Taunton, and the science teaching, which, after years of toil against obstacles, is just beginning to bear fruit, will become a thing of the past.

Austria.—The Austrian Government has for a number of years been accustomed to bestow liberal grants to the more promising students in the universities, under the condition that the recipients shall make use of them to undertake a course of study in the German universities. The results of this plan seem to be satisfactory, for we notice that this winter an unusually large number of students in all branches have been sent to the various universities in Germany.

A Berlin Polytechnic.—Berlin, with all her numerous educational establishments, has lacked hitherto a polytechnic such as is to be found in most of the German industrial centres at the present day. This want will soon be repaired, a commission having completed the plans for an extensive institution which will embrace nearly every branch of technical education. The plans for the necessary buildings have already been prepared, and as there is but little doubt that the Prussian Chamber of Deputies will grant the 9,300,000 marks required, the work of erection will commence next spring. On account of the extensive character of the proposed edifices, five years will be required for completion.

SOCIETIES AND ACADEMIES

London

Mathematical Society, December 13.—C. W. Merrifield, F.R.S., vice-president, in the chair.—The Rev. W. Ellis was elected a member.—Mr. S. Roberts read a paper on normals, which contained theorems depending on the invariants and covariants of the quartic equation representing a pencil of four normals to a conic, and drew attention to the remarkable cubic locus of the points of possible concurrence of these normals at the vertices of a given inscribed triangle.—Dr. Hirst and Mr. J. J. Walker spoke on the subject. Prof. Cayley, F.R.S., read a paper on "the geometrical representation of imaginary quantities and the real (m, n) correspondence of two planes."

Linnean Society, November 15.—Dr. Gwyn Jeffreys, F.R.S., vice-president, in the chair.—Mr. J. Jenner Weir exhibited a case of Alpine butterflies, interesting for their similarity to, though not specifically identical with, those obtained by the naturalists of the Polar Expedition.—Three papers on the Arctic fauna followed. I. Report on the Insecta including Arachnida, collected by Capt. Feilden and Mr. Hart during the recent Arctic expedition, by R. McLachlan. It seems there were obtained of Hymenoptera 5, Coleoptera 1, Lepidoptera 13, Diptera 15, Hemiptera 1, Mallophaga 7, Collembola 3, Araneida 6, and of Acarida 6 species, namely, a total of 57 species. Bearing in mind these are from localities between 78° and 83° N. lat, that among them are thirty-five specimens of gaily-coloured butterflies and two species of humble-bees, and it becomes evident the insect-fauna of this so-called "land of desolation" is, after all, not so meagre as anticipated. The paucity of beetles and abundance of butterflies are each striking features. From variations in certain well-known species obtained, Mr. McLachlan suspects they represent a local fauna, and he regards the latter as having affinity to the Lapland fauna, inclining to think both are but lingering remnants of a once former and extensive circumpolar fauna.—II. Preliminary notice on the surface fauna of the Arctic Seas as observed in the recent Arctic expedition, by Dr. Edw. L. Moss (late surgeon, H.M.S. *Alert*). The author observes that the seas north of the Greenland settlements are subject to such varying conditions at different seasons of the year that their surface-fauna cannot be supposed to be very constant. Nevertheless, judging from what fell under his observation during the voyage, he divides the watery area into three zoological regions: (*a*) A district in the latitude of Melville Bay, temporarily monopolised by infusoria, *Peridinea*: (*b*) a north-water region inhabited by Pteropods, Tunicates, and Hydrozoa; and (*c*) a sub-glacial region comparatively lifeless, so far as sea-surface implies.—III. On the annelids of the British North Polar Expedition (1875-76), by Dr. W. C. McIntosh. This collection, dredged between 70° and 82° N., was not so rich in numbers or species as that procured by the storeship *Valorous* in Davis Straits, but some eight species were got which were not among the latter's collection. None are new, but notwithstanding they help to render clear some points in the geographical distribution of the marine worms, so far as the circumpolar area is concerned.—Dr. H. Trimen exhibited specimens of the Olibanum, or Frankincense tree (*Boswellia carterii*, Birdw.), gathered by Mr. J. Collins from the trees planted at Aden. Dr. Trimen, in making some remarks on the variability of the foliage of the species of *Boswellia*, expressed the opinion that *B. Bhau-Dajiania*, Birdw., was not specifically separable from *B. Carterii*. *B. Frereana*, which yields the fragrant resin called "Luban Metyi," and which Hanbury considered to be the African "Elemi," is much chewed by Orientals, but rarely imported into England. It is found in the Somali land, where Hildebrandt recently collected it.—The following gentlemen were elected Fellows of the Society: Mr. W. S. Lawson, Mr. W. Joshua, and the Rev. M. A. Mactherd.

Geological Society, December 5.—Prof. P. Martin Duncan, F.R.S., president, in the chair.—Dr. Isaac Bayley Balfour, David Burns, Samuel Cooke, Henry Drummond, Sandford Fleming, Rev. John Hodgson, William Etheldred Jennings, Henry Merryweather, Robert Robinson, Martin Stewart, George Eastlake Thoms, Robert F. Tomes, and Irwine J. Whitty, were elected Fellows of the Society.—A portrait of Mr. J. Evans, D.C.L., F.R.S., V.P.G.S., was presented by the President.—The following communications were read:—On the building-up of the White Sinter Terraces of Roto-Màhànà, New Zealand, by the Rev. Richard Abbay, M.A., F.G.S.—Additional notes on the Dimetian and Pebidian Rocks of Pembrokeshire, by Henry Hicks, F.G.S. The additional facts communicated by the author show that at a distance of about ten miles to the east of the Dimetian axis of St. David's there is another ridge of these rocks, which also runs nearly parallel with it. This is also flanked by Pebidian and Cambrian rocks, and made up of rocks like those in the St. David's axis. The Dimetian formation, so far as it is at present known, consists chiefly of the following rocks:—1. Quartz porphyries, containing frequently perfect quartz crystals (double pyramids), subangular masses of quartz, and crystals of felspar in a felspathic matrix. 2. Fine-grained greyish quartz-rocks, very compact, and interstratified with the above. 3. Ashy-looking shales of a dull green colour, sometimes highly indurated, but usually showing lines of lamination. Microscopically these show basaltic characters, and are probably greatly altered interbedded basaltic lavas. 4. Compact granitic-looking rocks. 5. Quartziferous breccias. 6. A series of compact quartzites and crystalline schists, interstratified by green and purple altered basaltic lavas, with a slaty and schistose foliation, and by some dolomitic bands. Of the *Pebidian* formation new areas were added, and the portions described in the author's previous paper were further extended, and details as to the chief mineralogical characters added. At the base of the series resting unconformably on the Dimetian is seen an agglomerate composed of large angular masses of a spherulitic felstone, pieces of quartz and quartzites, indurated shales, crystalline schists, &c., cemented together by a sea-green matrix of felstone. These are followed by conglomerates of the same materials, which are again succeeded by indurated shales, often highly porcellanitic in character, with a conchoidal fracture. These are followed by a thick series of silvery white and purplish shales and green slates, alternating with fine and rough ashes, often conglomeritic, hornstone breccias, felstone lavas, &c. The series, as exhibited at St. David's, has a thickness of over 8,000 feet; and as it is everywhere, so far as yet seen, overlapped unconformably by the Cambrians, it may probably be of much greater thickness. It evidently consists very largely of volcanic materials, at first derived from subaërial, but afterwards from submarine, volcanoes. These materials, however, were also undoubtedly considerably aided by sediments of a detrital origin. The whole series shows that the sediments have undergone considerable changes, but yet not sufficient to obliterate the original characters, and the lines of lamination and bedding are usually very distinct. That they were altered nearly into their present state before the Cambrian sediments were deposited upon them, is clear from the fact that the pebbles of the Cambrian conglomerates which rest immediately on any portion of the series are almost invariably made up of masses of the rocks below, cemented by gritty materials on an unaltered matrix, and from which the pebbles may be easily removed. The great conglomerates at the base of the Cambrians, everywhere in Wales, indicate that there were beach- and shallow-water conditions over those areas at the time, and that the sea was then encroaching on an uneven land, becoming gradually depressed to receive the subsequent Cambrian sediment.—On some pre-Cambrian (Dimetian and Pebidian) rocks in Caernarvonshire, by Henry Hicks, F.G.S. In this paper the author gave an account of the special examination of the great ribs of so-called intrusive felspathic and quartz porphyries which are found associated with the Cambrian rocks in Caernarvonshire, made by him in company with Prof. Hughes, Mr. Hudleston, and Mr. Homfray last summer.—On the pre-Cambrian rocks of Bangor, by Prof. T. McKenny Hughes, F.G.S. The author described a series of slates, agglomerates, and porphyritic rocks which, near Bangor, are seen to pass under the Cambrian and seem to rest conformably upon the quartz felsites and granitoid rocks of Caernarvon. He considered that in the main the Bangor beds were the equivalents of the Pebidian of Dr. Hicks, while the Caernarvon beds nearly represented his Dimetian. But he thought there was as yet no proof of an unconformity between these formations.—An appendix by Prof. Bonney, on the microscopical examination of the rocks referred to, accompanied this paper.

Royal Microscopical Society, December 5.—Mr. H. C. Sorby, president, in the chair.—The president announced that in consequence of the death of Dr. Lawson it had become necessary to reconsider the subject of publication, and the Council had, after careful attention to the matter, decided in future to publish their own proceedings.—A paper by Herr Zeiss on Abbé's apertometer was read by Mr. Ingpen, who exhibited the apparatus to the meeting and further explained its construction and method of application by means of black-board diagrams. Mr. Ingpen also described the method of measuring angular apertures last adopted by Mr. F. H. Wenham.—A paper by Mr. F. A. Bedwell on *Cephalosyphon* was read by Mr. Slack, who afterwards explained the structure of this rotifer, and pointed out the special features to which attention was drawn by the author of the paper.—Another paper by the same author on a new method of examining *Actinia mesembryanthemum*, was read by Mr. Chas. Stewart; it was illustrated by drawings, some of which were enlarged upon the black-board.

Institution of Civil Engineers, December 11.—Mr. George Robert Stephenson, president, in the chair.—A description of Cofferdams used at Dublin, Birkenhead, and Hull, by Mr. William James Doherty, Assoc. Inst. C.E., was read.

GÖTTINGEN

Royal Academy of Sciences, August 24.—The division of a language into several different languages, by M. Benfery.—On the earthquake of Iquique on May 9, 1877, and the tidal movements thereby produced in the ocean, by M. Geinitz.

November 7.—Report on the Physical Institute (department of experimental physics), from 1871 to 1877, by M. Riecke.

November 14.—D instead of N, by M. Benfery.—Contributions to physiography of rock-forming minerals, by M. Lang.

November 21.—Antiquities in the south-west of Switzerland, and in Turin, by M. Wieseler.—On the secondary intestine of the echinoideæ, by M. Ludwig.—Obituary notices of M. Hartmann and M. Marx.

PARIS

Academy of Sciences, December 10.—M. Peligot in the chair:—The following papers were read:—On some applications of elliptical functions (continued), by M. Hermite.—On invariants, by Prof. Sylvester.—On the arrangements which, in the system of a navigation sluice with single oscillation, conduce to the maximum of production and the minimum of expense of construction, by M. De Caligny.—On the development of eggs of the phylloxera of the oak, and the phylloxera of the vine, by M. Boiteau.—M. Volpicelli sent a note tending to prove, by means of potential, that induced electricity of the first species has no tension.—Application of Leyden jars of large surface for distributing, at various points, the effect of the current from a single source of electricity, with strengthening of the effect, by M. Jablochkoff. Connecting one surface of such an apparatus (called in this case an *exciter*) with one of the conductors of a machine which gives alternate currents, an alternating current is got by the other surface of the exciter and the second conductor (or the earth), more powerful than the current given directly by the machine. If a series of exciters with surfaces of nearly 500 square metres be thus connected with a machine which gives a spark equivalent to that of six or eight Bunsen elements, a voltaic arc of 15 to 20 mm. is obtained, and carbons of 5 mm. diameter are reddened to an extent of 6 to 10 mm. from their extremity. Such effects are utilised in electric lighting.—On the law of absorption of radiations through bodies, and its employment in quantitative spectrum analysis (continued), by M. Govi. He shows how *surfaces of chromatic absorption* may be obtained by means of the analysing photometer, measuring the various simple radiations which take part in a complex radiation.—On some properties of chloride of calcium, by M. Ditte. He deals with the calorific phenomena accompanying the reaction of water with this chloride. If the latter be anhydrous, a heating is observed, and fresh additions of water cause successive heatings; but if the chloride be hydrated, its mixture with water produces at first a considerable cooling followed by heating if some more of the solvent be added.—Application of palladium wire to determination of the hydrocarbons mixed in a small proportion with air, by M. Coquillion. It is necessary to operate with a cherry-red, near white-red. The results agreed with theory.—On the development of the functions of M. Weierstrass according to the increasing powers of the variable, by M. André.—On the lesions of the nervous system in diphtheritic paralysis, by M. Dejerine. There is an atrophy of the anterior roots, which follows destruction of the cells of the anterior horns of the spinal cord, by a process similar to that of myelitis.—Orography, by M. Schrader. The author presented a geographical map of Mont Perdu, made with his orograph, which consists of a circular paper-covered plate with central vertical axis carrying a sleeve which can turn round freely. On the top of the sleeve is a telescope, the movements of whose frame in the vertical direction are communicated to a pencil, and transformed by gearing into to and fro movements. If the telescope describes a circle round the horizon, the style describes a corresponding circle on the plate; if the telescope goes up or down, the trace produced is further from or nearer to the central axis. A spirit level being fixed to the telescope, the circle made when it is even, gives a means of estimating the heights and depressions.—On the folding of the lacustrian strata of Auvergne in Central Limagne, and its consequences, by M. Olivier.—Influence of soil and forests on climate; temperatures of air layers over woods; consequences as regards vegetation; effects of currents arising from differences of temperature under wood and beyond wood, by M. Fautrat. The frigorific action of the forest is very manifest in the hot season. Under pines in September the temperature is lowered 1·60°. Pure sand raises the temperature of a place. Leafy woods, during vegetation, produce a slight lowering of temperature in the atmosphere above. Above pines, in the daytime, there is always a rise of temperature, from the solar heat being retained by the vapours enveloping the tree-tops. From the differences of temperature within and without woods, a current arises in the wood from below upwards, and round the woods course lateral currents from the wood to the plain.—On the disinfecting properties of cellulosic substances carbonised by concentrated sulphuric acid, by M. Garcin.

THURSDAY, DECEMBER 27, 1877

THE METROPOLITAN SEWAGE

THE question of the effect of the main outfall sewers of the metropolis on the reaches of the Thames below London has occupied the attention of engineers not only since the completion of the works, but throughout the long series of years when those works were under consideration. Some persons qualified to make accurate observations and draw correct deductions from them, asserted that large masses of deposit were directly due to these outfalls, and were daily increasing in magnitude, while others, demanding equal confidence in their statements, asserted that no such deposits existed—in fact, that the sewage outfalls tended to improve the bed of the river by increased scour; thus the bulk of engineers for a long time held diverse views or suspended judgment on the subject, while the general public, not knowing whom to believe, trusted it would turn out all right in the end. Inasmuch as the Metropolitan Board of Works is bound, under the Thames Navigation Act of 1870, to keep the Thames free from banks and other obstructions to the navigation due to the flow of sewage from their outfalls, and to carry on all dredging operations required for that purpose, at their own expense, the vision of the possible cost of these works to the London ratepayer is unlikely to be pleasing; still less could any interference with the highway to the most important port in the world be tolerated by the Board who were looked to for its preservation. In 1869, the metropolitan main outfalls having been opened in 1863–64, the Home Secretary appointed Mr. Rawlinson to hold an inquiry on the reported silting up of the Thames, which was then causing great alarm; such, however, was the contradictory nature of the evidence, that the result was almost nugatory, and the question still remained in abeyance. In the course of the last summer the Thames Conservators requested Capt. Calver, R.N., F.R.S., to direct his attention to the subject, and report to them thereon. Before pointing out the conclusions arrived at by Capt. Calver,[1] it will be as well to direct attention to the part of the river under consideration. The northern outfall is situated immediately above Barking Creek, which forms the embouchure of the river Roding, and is about two miles below Woolwich; the southern outfall is about 2½ miles lower, or 4½ miles below Woolwich.

In the face of the fact that this special inquiry was held and many competent witnesses examined with the sole object of determining whether or no the sewage outfalls have caused a silting up of the river in their neighbourhood, or the formation of shoals and mudbanks, and that so many observations and statements have since been made with the same view, it seems perfectly monstrous that the question should still remain unsettled. In the report now before us we have the last contribution on the subject, or perhaps, with more fairness it might he said the last but one, as since its publication Sir Joseph Bazalgette has addressed to the daily press a letter containing a direct denial of many of the conclusions there arrived at. When professional experts differ so entirely not only in their conclusions, but also in the facts upon which these conclusions are based, we see no other course open but to appeal to the cooler and more unbiased judgments of pure science.

In comparing the analyses of Thames mud from various parts of the river, given in Capt. Calver's report, embodying a series taken in 1867, and another in 1868, by the late Dr. Letheby, with those given by Dr. W. A. Miller, and Dr. W. Odling in 1869, so close an agreement is manifest that a safe conclusion can be drawn from them. The analyses are as follows:—

Average Percentage Composition.

Organic matter	15·00	14·19	1867	Dr. Letheby.
Mineral ,,	85·00	85·81	1868	,,
	100·00	100·00		

On these analyses Dr. Letheby remarks that the above percentage proportions did not differ materially from the quantities of organic and sewage matters which he found suspended in water at London Bridge, and in the mud at London Bridge, Chelsea, and Westminster, when the sewage was discharged at low water. The next table gives nearly identical results from the analysis of the mud at the outfalls in 1867, and those of the suspended matter in the Thames water at Greenwich, Woolwich, and London Bridge in 1862, by the same chemist. Now, Dr. W. A. Miller so far agrees with these results that in his evidence, given at the inquiry before referred to in 1869, he states the percentage of organic matter in the mud taken from Barking Creek to be 16·2, from the Thames between Chiswick and Westminster, 15·8, and further, that of these two quantities 3·1 and 3·05 respectively consists of nitrogen, and finally, in answer to the question: "But there is nothing special and differing in the mud at Barking from the ordinary mud of the River Thames?" he says: No, the composition is as nearly the same as may be. With these observations Dr. Odling's evidence closely agrees.

Here, then, we have an agreement which nobody appears to dispute, and which leads inevitably to the conclusion that the great bulk of noxious putrescible matter left uncovered at low water throughout the whole of the tidal portion of the Thames owes its deleterious character mainly, if not entirely, to the presence of sewage matters.

Having carefully pointed out and established this identity of composition, Capt. Calver proceeds: "It is, however, equally necessary to prove that there is enough of this material in the sewage discharged from the outfalls to account for the large accumulations of it which have found a resting-place in the Thames channel." Here we are met by estimates differing in the wildest manner, and varying from 35 to 100 grains per gallon, and again to nearly double that amount, but fortunately we are here even given material for a trustworthy estimate. In the table of analysis given by Prof. Williamson of samples taken from the northern outfall in September of this year we find 108·01 and 151·45 grains per gallon as the actual amount of suspended solid matter at different times, the samples being collected in fine weather. Now abundant evidence has been given at various times, showing that after heavy rain the sewage contains an amount of solid impurity equal to, if not greater than, that in the fine-weather flow; thus there can be no doubt that the lower of these two figures is not in excess of the average. Capt. Calver takes the amount at 100 grains per gallon, and multiplying by the daily discharge quoted as 120 million gallons, he obtains a result of 279,225 tons per annum. This probably does not exceed one-half the true amount, as the water supply of the metropolis alone reaches the amount assumed for the daily discharge, and the rainfall over the drainage area gives nearly an equal amount, which, for the reason just stated, must be taken into account. We thus appear to have at command upwards of half a million tons of suspended matter discharged into the Thames in each year, which is amply sufficient to account for the deposits observed. Thus we read in the report that "Mr. Leach (the engineer of the Thames Conservancy Board) reported in December (1871) that a deposition of 7 feet 9 inches of mud had formed between the upper end of the southern embankment and the White Hart Draw Dock, Lambeth; that another bank 100 feet wide and 6 feet thick occupied the river-frontage of St. Thomas's Hospital, &c. By July of last year a material portion of these masses had been cleared away by excessive rainfalls." Are we to be left to the mercy of such an unpleasant remedy as the floods of last autumn to abate a nuisance of such magnitude, threatening, as it does, the existence of such an institution as St. Thomas's Hospital, and showing how soon we may return to the unsanitary state of affairs that existed twenty-five years ago? We have purposely avoided dealing with an equally important part of Capt. Calver's report, in which he points out the danger of the silting up of the navigable channel of the Thames below London, as he has not shown that the sectional area, though varying from year to year, has at any point permanently diminished, still the destructive elements have been shown to exist, and the forces which now hold them in equilibrium may at any time be thrown out of balance and the evil creep on imperceptibly if once the eyes of the public are closed to its existence. Without going into the question of the value of the sewage estimated by the highest authorities at 1,000,000*l.* per annum, thus not only wasted but employed as a powerful obnoxious agent, enough has been shown from the report before us to, we hope, show the suicidal folly of discharging sewage wholesale and unpurified into tidal rivers. Yet even now a scheme is under consideration for the collection of the sewage from a large area in the Thames Valley and for its discharge into the tidal waters of the Thames. We believe that a careful perusal of Capt. Calver's Report will dispel from the minds of the Thames Valley Joint Board all hopes of a satisfactory though expensive solution of their difficult problem being arrived at in this manner. As a remedy for the state of things he has shown to exist Capt. Calver recommends that in pursuance of the powers they possess the Conservancy Board call upon the Metropolitan Board to dredge away the obstructions they have caused; this may be indispensable at present and may be an unavoidable and constantly recurring expense until some profitable scheme is devised for utilising the metropolitan sewage; in the meanwhile the example of the inhabitants of Abingdon, as shown by the letter of their medical officer of health in the *Sanitary Record* of November 30, shows the inutility of other towns in the valley of the Thames striving to follow the example of London, and further increasing its difficulties. We learn from Dr. Woodforde's letter that the whole of the sewage of the town of Abingdon is purified by filtration through natural soil being frequently absorbed by one acre of land, and that the amount of organic and inorganic impurity contained in the effluent water after passing through the land is far less, in some cases less than one half that contained in the well water used for drinking purposes in the town. As this unprecedented result has been obtained on land of a character which exists in abundance throughout the Valley of the Thames we think that the towns situated therein have not far to look for the solution of their difficulties.

---

[1] "Report upon the Discharge of Metropolitan Sewage into the River Thames at Barking Creek and Crossness." By Capt. E. K. Calver, R.N., F.R.S.

BOTANY IN GERMANY

Jahrbücher für wissenschaftliche Botanik. Herausgegeben von Dr. A. Pringsheim. Elfter Band. Erstes und Zweites Heft. (Leipzig: W. Engelmann, 1877.)

THE second decade of volumes of the Jahrbücher is now begun, and up to the present shows no sign of any falling off from the high standard of excellence attained by the former parts It is somewhat remarkable that such a work can be carried on successfully. Profusely illustrated (having about 500 plates in the ten vols.), and containing papers of great merit, it is at once evidence of the marvellous botanical activity of the Germans, and the energy of their publishers. A glance at the list of papers in the ten volumes shows that the Jahrbücher contain papers that have become classical, and have been contributed by men who have risen to the highest eminence in botanical science. Comparatively few of the papers are contributed by Russians or Italians, hence this one work may be looked upon as almost wholly the result of German research. The papers contributed are chiefly morphological and physiological, although occasionally one having immediate bearings on taxonomy is introduced. There can be little doubt that the German university system tends greatly to foster original research, not only in botany, but in all other departments. The botanical institutes, with laboratory, garden, and herbarium attached, the way in which the students are induced not only to learn but to work under the superintendence of the professor, the whole system of private teachers and mode of promotion of the professors fosters research, and gives a thoroughness and heartiness to the work. In certain departments of botany, Britain is second to none with her Hooker, Bentham, and Darwin, but when we consider the enormous "microscope" power of Britain, we cannot help thinking that much of it goes to waste. There must be hundreds of microscopists residing near our coasts, yet what do we know of the reproduction of our algæ? A glance at the "Botanischer Jahresbericht" shows how few British botanists there are, and also that each contributes comparatively few papers per year. But quality is better than quantity—work slowly and well. The time is no doubt coming when we may look for increased botanical activity, perhaps the union of botanical studies to medicine has had something to do with the comparative depression, and if botany becomes a preliminary instead of a purely professional study by becoming more diffused, a greater taste for the subject may arise.

Prof. Pringsheim contributes the first paper, one part dealing with the interesting subject of the budding of the fruit of mosses, the second on the alternation of generation in the Thallophytes, a subject suggested by the first part. If the seta of the ripe fruit of the moss be cut into pieces, and the pieces cultivated on wet sand, protonema threads will grow from the cut portions, and produce the usual buds, exactly like protonema threads developed from the spores or stem and leaves of mosses. The anatomical connection of the protonema with the tissue of the seta can be observed in good longitudinal sections. Not all the cells can give rise to protonema, but only those of the middle zone, situated between the peripheral cortical cells and the central bundle. These cells contain abundance of reserve matter, such matter being found in many parts of the moss-fruit. The product of protonema by the seta of the moss is to be compared to the budding of the prothallium of ferns described by Farlow. Pringsheim figures in the two plates illustrating the paper, the protonema developing from the seta of *Hypnum serpens*, *H. cupressiforme*, and *Bryum caespitosum*, and he shows the stem and seta to be identical structures.

The second part of the paper, on the alternation of generation in Thallophytes, is difficult to follow without illustrations, as it takes for granted that the reader is acquainted with all the recent researches on the lower plants. Pringsheim distinguishes between sexual alternation of generations and vegetative alternation of generations (sprosswechsel), the fructification and vegetative propagation. All the generations of Thallophytes (as well as of the Cormophytes) begin with one free cell (the spore). The generations in the Thallophytes represent free individual plants, while in the Cormophytes the generations remain in organic connection and in their individual sequence appear only as two portions of one series of developments. From this it follows that the "fruits" of Thallophytes never have the value of a "generation," and also that where the development is due to sexual influence, they are only sexually influenced organs of the female plant. Such parts are the fruits of *Florideæ*, also apparently the Perithecia and Apothecia of Ascomycetes, which do not behave differently from the calyptra of the moss or the thickened tissue (gewebepolster) of the prothallum, in which the embryo of the vascular cryptogams is developed. Pringsheim believes that in the trichogyne and ascogon the influence of fertilisation is spread from cell to cell until it reaches the spores, just as in mosses and ferns the reverse process occurs, and the influence spreads from the fertilised germinal cell to the archegonium. Carpospores and ascospores are therefore to be regarded not as sexually-produced spores of a sexually-produced generation, but as truly sexually-produced spores, developing in the sexually-influenced organ of the mother plant.

The second paper, illustrated by two plates of diagrams, and occupying nearly half the part, is by F. G. Stebler, "Researches on Leaf-growth." The numerous observations made on *Allium Cepa*, *Secale cereale*, *Triticum vulgare*, *Cucurbita melanosperma*, are detailed at full length, and the following summary of the result of the paper is given at the conclusion. The leaf begins to grow very slowly, then growth becomes more rapid until a maximum of rapidity is reached; then growth becomes slower and slower until at last it ceases. The leaf thus behaves like other growing parts of plants. The growth of the linear monocotyledonous leaf is basipetal. The apex zone of the leaf ceases earliest to grow, then succeeding zones in basipetal order, until lastly the growth of the basal zone terminates the growth of the entire leaf. Most productive of increase in length is the growth in the basal zone, but at different times the maximum activity is in different zones, the absolutely greatest zone of growth proceeding in succession from the upper part of the leaf to the lower. The maximum period of growth of the whole leaf is the sum of the maximum periods of all the zones.

The linear monocotyledonous leaves examined in reference to alternations of growth by day and night showed a daily periodicity of growth, the growth diminishing as the intensity of the light diminishes. The maximum of growth corresponds to the greatest intensity of light; the minimum is observed to occur shortly before sunrise. The cause of the daily periodicity of growth is assimilation; as assimilation increases the growth increases; as it diminishes the growth diminishes.

The same daily periods of growth were observed in etiolated linear monocotyledonous leaves in the dark, the external conditions being constant. The periodicity has thus been transmitted.

In the dicotyledonous leaves observed the daily periods were modified, so that after the maximum of growth was reached in the forenoon a retardation took place, and a gradual diminution of the growth till the following morning before sunrise. At daybreak the growth rapidly increases again to reach a maximum in the forenoon. If the intensity of the light is small the maximum is later of occurring than if the light be very intense.

The maximum of the day periods of growth of the dicotyledonous leaf is due to the assimilation. The retardation during the day occurring after the maximum of growth (but not the maximum of light) has been reached, is due to the action of the light.

The third paper occupying the remainder of the part is by Dr. Celakovsky, and is entitled, "Teratological Contributions to the Morphological Import of the Stamens." It is illustrated by three plates. Considerable uncertainty still exists as to the morphological value of the different parts of the stamen, but more especially of the anther. The difficulty does not exist in regard to the pollen-bearing caulomes, but there are still difficulties in those cases where the stamens are modified leaves. Whether the question can be settled by the study of the development alone is a matter of doubt, even after the valuable researches of Warming and Engler on the subject; and it appears likely that the most important results may be expected from the careful study of the numerous abnormalities of stamens so constantly met with. The scientific study of the teratological developments of stamens must therefore be looked upon as of the highest importance, and Celakovsky—already well known by his teratological researches, here describes and figures the changes (phyllody) of the stamens of *Rosa chinensis*, *Dictamnus albus*, and in the double flower of *Camellia japonica*.*

There are two important questions to be answered. 1. Are the pollen-sacs mere enlargements of the leaf-substance of the staminal leaf, or are they special developments somewhat like "emergences"? 2. Do these sacs belong to the under side, upper side, or both sides of the leaf; or are there differences of position in different plants?

Cassini and Roeper held that the pollen-sacs were cavities in the leaf-parenchyma, two forming on each side of the leaf, so that the margin of the leaf corresponded to the suture between the sacs. Mohl considered this view only to hold for certain cases, as the Euphorbiaceæ, and found, what Bischoff had already pointed out, that in all examples examined, as in poppy, rose, and nigella, the four pollen sacs were placed on the *upper* side of the leaf, and that the margin of the leaf ran along the two posterior or lower loculaments. Mohl did not consider the sacs as "emergences," and differing morphologically from the true leaf, as he says that the connective represents the central portion of the modified leaf, while the loculaments are the thick swollen lateral halves, which become contracted in length and breadth. Mohl considered that in the plants with extrorse anthers both the loculaments of each anther lobe were developed on the under side of the leaf. Alexander Braun pointed out in 1851 that the anthers were produced by doubling of the lamina (Ueberspreitung). This view was confirmed by Wydler in 1852, who compared the anther to the abnormal double lamina in the leaf of Bignonia.

Sachs considers the anthers to be appendages of the leaf. He compares each loculament in the anther of Cycads and Cupressineæ to Sporangia; the four pollen-sacs in the Metasperms being "emergences" from the upper side of the leaf, those of the Archisperms from the lower side. Braun still further examined the subject and confirmed his original views, namely, that the pollen-sacs do not belong to a simple leaf, but to one with a double lamina, the doubling due to the formation of an "emergence" (in Karl Schimper's, not in Warming and Sachs' sense). The two upper anther sacs belong to the "emergence," the two posterior to the original lamina of the leaf. Celakovsky in the paper now before us departs from the views published by him in *Flora* for 1874, and fully confirms the views of Braun and Wydler.

The second part of vol. xi. contains five papers by Pfitzer, Koch, Reinke, and Reinsch. Dr. Pfitzer's paper is on the rapidity of the current of water in the plants. It contains an elaborate series of researches, the first on the movement of leaves due to the absorption of water by the stem and root; the second by means of solution of lithium. Dr. McNab's experiments are extended and confirmed, but the astonishing rapidity of 22 metres per hour was observed in *Helianthus annus*, the greatest rapidity observed by Dr. McNab being 40 inches per hour in *Primus Lauro-cerasus*. Pfitzer also uses a solution of soluble indigo carmine 4 parts to 1,000, and finds that it is superior to solution of lithium, as it can be detected at once instead of using the spectroscope.

The second paper is by Dr. Ludwig Koch, on the development of the seeds of Orobanchaceæ. The development of the anatropal ovule, with one integument is described, and the development of the embryo. This agrees with the description given by Hanstein, of the embryo of Capsella. The endosperm is formed of divisions of embryo-sac, which contains antipodal vesicles before fertilisation. The third and fourth papers are by Prof. Reinke, both on the development and reproduction of algæ, of the genera Phyllitis, Scytosiphon, Asperococcus, and Bangia, the observations having been made at the Zoological Station at Naples, during the winters of 1875 and 1876.

The last paper is by Reinsch: "Observations on new Saprolegnieæ, on parasites in cells of Desmedicæ, and on the 'Spinous Spheres' in Achyla." A number of new species and genera are described and fully illustrated.

W. R. M'Nab

MOVING DIAGRAMS OF MACHINERY

Patent Working Drawings. By H. and T. C. Batchelor (London: Macmillan and Co.)

ALL who are engaged in the teaching of kinematics and of applied mechanics must often have it brought forcibly before them the difficulty that exists in making even comparatively simple mechanical motions intelligible to students by means of ordinary drawings and diagrams, while the more complex motions and combinations can hardly be treated of at all profitably without the aid of working models, which are very expensive, and take up a great deal of space. Again, inventors and the proprietors of patented mechanical inventions, are often at a loss to explain to unscientific or uninitiated persons the advantages of their systems, and costly working models have to be resorted to in order to avoid the mystification which ordinary mechanical drawings often produce in the minds of those not accustomed to them, or who are not versed in the principles of mechanics.

To supply this recognised need of teachers and others, Messrs. H. and T. C. Batchelor have designed and worked out a most ingenious system which combines the mechanical movements of a model with the flatness and clearness of a diagram. The name "Working Drawings" applied to these diagrams is somewhat misleading, especially to engineers and others accustomed to this term as having a distinct and special meaning, namely, drawings made for and used by the workmen employed upon the construction of machinery to work from. Working drawings are essentially drawings for the workshop, and that is the universal acceptation of the word. The meaning attached to it by Messrs. Batchelor is, however, very different; it is drawings which will work moving diagrams. This sense is, perhaps, more critically correct, but as another meaning is the generally accepted one, we cannot but think that it would have been wise if a name had been given to these diagrams more descriptive of what they are. They are, in fact, moving diagrams or sectional working models of machines, the fixed parts being lithographed as a background upon a firm cardboard mount, and the moving parts being also lithographed on card, but cut out and jointed together by most ingenious mechanical contrivances; the whole being no thicker than a sheet of stout cardboard.

The perfection of the centres upon which the various parts revolve or are pivoted together must be seen to be adequately appreciated, for while these centres allow perfect ease of motion to all the parts, they are absolutely steady and without the slightest shake. It is this system of centring that constitutes the patent by which Messrs. Batchelor's drawings are protected. The pivots are made entirely of card and paper cut in a most ingenious manner, by which both freedom and steadiness are insured. Nor are the centres the only parts of these drawings interesting for their ingenuity; the contrivance for holding down the sliding parts is equally good. It consists of a band of thin paper passing over the sliding part, and printed exactly like the part it covers, so that it is invisible except on close examination.

The first of these drawings which is before us is a diagram in illustration of the action of the "trunk engine," the characteristic feature of which consists in making the piston-rod hollow and of sufficient internal diameter to allow the connecting-rod to be attached at one end direct to the piston, and to oscillate within the trunk, the other end embracing the crank-pin. By this means the crank shaft can be brought nearer to the cylinder, considerable space thereby being saved, and the alternative system by which direct connection between the piston and crank is effected, viz., the oscillating cylinder, is avoided, with its more complicated valve gear and expensive construction.

The double trunk system represented in the drawing was the invention of the late Mr. John Matthew, who for many years was a partner in the eminent firm of Messrs. John Penn and Sons, and it is the system upon which, almost without exception, the large screw engines of Messrs. Penn are constructed, with which so many of the ships in her Majesty's navy are fitted.

There is nothing to be desired in the execution of the diagram before us, of which the name of Messrs. Maclure and Macdonald is a sufficient guarantee. It is lithographed in white upon a blue ground, and all the parts come out with singular distinctness. We could have wished that, in the choice of an example for illustration, a more modern design of engine had been selected. The eccentric rod, with its lattice bracing, is that employed in the old beam engines, and a trunk engine made to the drawing before us could hardly work, for the crank pin is evidently inserted into one of the spokes of the fly-wheel, and unless projecting to an impossible extent, the trunk could not clear the wheel; this could very easily have been remedied by showing the "throw" of a crank behind the connecting-rod, which would have aided rather than detracted from the clearness of the diagram.

While thus criticising the particular design of engine selected for representation, we can only express admiration of this most ingenious system of illustrating mechanical motions and the action of machines. For educational purposes it will be of the highest value, and there are many of the examples in Reuleaux's masterly work upon the "Kinematics of Machinery,"[1] so ably translated by Prof. Kennedy, to which it might with great advantage be applied.

We feel sure that Messrs. Batchelor's drawings will be a great boon to inventors for explaining their inventions to others; and as supplementary to scientific evidence in disputed patent cases and other litigation, they will be found of value.

C. W. C.

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.

The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.]

Oxygen in the Sun

FROM the time of the discovery by Prof. Draper of the presence of oxygen in the sun down to the present moment I have devoted most of my leisure time to the consideration of the question as to why the oxygen lines should appear *bright* while the metallic lines should appear dark in the solar spectrum. I was led into this inquiry under the firm belief that the new fact made known by Dr. Draper might lead to a modification of existing views of the sun's atmosphere, and it was consequently with the greatest pleasure that I read in last week's NATURE a communication from Dr. Schuster on this subject.

The views which I have arrived at being in my opinion hardly matured enough for publication, I reserve further statement at present, but will so far anticipate as to say that the explanation which I am disposed to maintain necessitates the assumption that oxygen possesses two different spectra—a low temperature band-spectrum and the well-known line-spectrum of high temperatures. This assumption I thought warranted by the behaviour of other non-metals as made known by the researches of many spectroscopists, but more particularly by those of Salet and Lockyer, and endorsed by the low temperature absorption spectra of the metals discovered by Roscoe and Schuster, Lockyer and Roberts. The recent research of Dr. Schuster, however, has now placed this assumption in the position of a fact, and all who have followed recent spectroscopic advancement will recognise the value and importance of this last discovery.

As Dr. Schuster's explanation of the brightness of the oxygen lines differs fundamentally from that which I am inclined to hold, and as he considers this view warranted by the result of his investigation, I will beg permission to make a few brief remarks upon the chief points of difference between us, being convinced that their discussion cannot fail to elicit opinions of interest to all concerned in the progress of solar physics. This ventilation of opinion is the more necessary as views very similar to, if not identical with, those of Dr Schuster's had occurred to me and had been abandoned for reasons which I will now explain.

According to Dr. Schuster, "the temperature of the sun, at some point intermediate between the photosphere and the reversing layer" is the same as that at which the spectrum of oxygen changes; that is to say, if I rightly interpret these words, *above the photosphere* the temperature is such that we get the line spectrum of oxygen and *above the reversing layer* the temperature is such that we get the band ("compound line") spectrum. This state of affairs would doubtless account for the reversal of the "compound line" spectrum which Dr. Schuster has now shown to be present in the solar spectrum, but I fail to see at present how it is to be reconciled with the *bright* line oxygen spectrum. Let us consider the conditions more closely. All observers agree in placing the reversing layer at the base of the chromosphere—the present hypothesis necessitates a space between the photosphere and the reversing layer—*i.e.*, a space sufficiently extended to contain the incandescent oxygen giving the line spectrum. Neglecting for the present the antagonism between these views, let us assume that such a space exists, and for the sake of simplicity let us also neglect the other elements which may be present. Now it cannot be assumed that the supposed zone is *higher* in temperature than the photosphere—it *might be* of the same temperature, but, being above the photosphere it would more probably be at a *lower* temperature. Let us, however, make the assumption most favourable to Dr. Schuster's view, viz., that the hypothetical zone is of the same temperature as the photosphere. Then we have a zone of oxygen exterior to the photosphere and of the same temperature as this last region, and above the oxygen the cooler reversing layer. Thus the light of the photosphere passes unchanged through the oxygen zone, and we should see no dark lines corresponding to the line-spectrum of this gas.—As a matter of fact, however, the oxygen lines are *bright*—hence it must be at a higher temperature than the photosphere, or we must be looking through an enormous stratum of it, a stratum thick enough for the radiation of the gas to overpower the fierce glare of the photosphere behind it, and both these views have been shown to be untenable.

December 21 R. MELDOLA

Oxygen in Sea-water

AT p. 267 of the second volume of the "Voyage of the *Challenger*," Sir Wyville Thomson writes:—

"Mr. Buchanan drew the conclusion in explanation of the small amount of oxygen at depths of 300 fathoms and upwards, 'that animal life must be particularly abundant and active at this

ditions the most unfavourable to animal life, is produced and maintained by its excess."

"This is entirely contrary to experience."

The words in inverted commas are part of a sentence in a short report in NATURE (vol. xvi. p. 255), of a paper which I read before the Royal Society of Edinburgh, on the results of the analysis of so many of the samples of air extracted during the cruise, from sea-water of different sources, as I was able to accomplish before my connection with the work of the expedition ceased. I will not encroach on your valuable space by anticipating the discussion of the bearing of my observations and those of others on the question of the greater or less abundance of animal life at different depths in the sea; but as the above quotation, from its fragmentary character, is somewhat misleading, both as to the nature of the belief which I expressed and my grounds for holding it, I must ask you to give place to the concluding sentences of the above report:—

"It is evident from these figures[1] that between 200 and 400 fathoms there is a great consumption of oxygen going on, and, as it is difficult to conceive its being consumed otherwise than by living creatures, the conclusion is forced on us that animal life must be particularly abundant and active at this depth, or, at least, more abundant than at greater depths; for at less depths there is more opportunity for renewal of the oxygen by reason both of the greater proximity to the surface and of the existence of vegetable life. This conclusion was borne out by the numerous experiments made by Mr. Murray with the tow-net at intermediate depths, which went to prove the existence of abundance of animal life down to 400 fathoms, vegetable life never extending to much below 100 fathoms. Below 400 fathoms life is sparingly met with."

It will be seen that the only independent experience which exists, namely, Mr. Murray's observations with the tow-net at different depths, is in favour of the conclusion at which I arrived.

J. Y. BUCHANAN

10, Moray Place, Edinburgh, December 13

On some Peculiar Points in the Insect-Fauna of Chili

FOR some years past I have been particularly interested in some points in the entomology of Chili and the extreme southern portion of South America, which, although known to most entomologists who have made special groups their study, have never yet been, so far as I know, even more than casually alluded to in works on geographical distribution, and are ignored in the principal ones. I allude to the occurrence in that part of the world of well-marked palæarctic or nearctic forms not found otherwise in America south of Mexico, and utterly unknown in the southern hemisphere in the Old World.

I have collected a not inconsiderable amount of data concerning this subject, and have the intention of addressing a circular to zoologists and also to botanists, asking for further information.

I will here allude to such familiar genera as *Carabus* amongst beetles and *Argynnis* and *Colias* amongst butterflies. *Carabus* is very abundant in species in the palæarctic region, poor in the nearctic, and reappears (for the whole world) only in Chili. The distribution of *Argynnis* and *Colias* is similar, only that they are about equally abundant in the two northern regions, and of *Colias* it appears probable that a single species occurs in Peru, but this exception only proves the rule.

In the *Trichoptera*, or Caddis-flies, a group of insects in which I am especially interested, there is even a still more striking case. The typical family, *Limnophilidæ*, comprising those insects the larvæ of which manufacture the cases of twigs and straws, so abundant in our ponds and ditches, and which is so rich in species in northern regions, is not, with the exception stated below, known south of Mexico in the New World nor south of the Himalayas in the Old; but I have several species from Chili, Araucania, and the Falkland Isles.

I could already multiply parallel instances, but have said enough to prove my case.

Confessedly I have, at present, only crude theoretical notions on the causes of this anomalous distribution. It might be said that these insects are the remains of a former Antarctic glacial epoch. But if this be so, then we must presuppose the existence of former Arctic and Antarctic faunas similar in details; all other evidence tends, I think, to disprove this. It may truly be said that, owing to the non-existence of large tracts of land towards the south pole at all comparable with those that exist towards the north, we are not in a position to acquire sufficient data, yet we have the continent of Australia and the large islands of New Zealand extending somewhat far south, and they furnish us with no indication whatever of forms parallel with those found in Chili.

It has occurred to me as just possible, that at the conclusion of the northern glacial epoch a few stragglers, instead of wending their way northward, mistook the points of the compass and went southward. But there remains this great difficulty, viz., that, with one possible exception, there are no indications of these forms on the northern portions of the Andes of South America.

I call attention to this subject as one deserving far more consideration than it has hitherto received, and with the idea that, by ventilating it in NATURE, I may receive additional information on a point that greatly interests me.

39, Limes Grove, Lewisham R. McLACHLAN

Arctic Auroræ

IT will probably interest some of your readers to know that in reply to a communication lately addressed by me to the Admiralty I am informed that Captain Sir George Nares reports that although the auroral glow was observed on several occasions between October 25, 1875, and February 26, 1876, true auroræ were seldom observed, and the displays were so faint and lasted so short a time that the spectroscopic results were not considered worthy of a special report. Although the citron line was seen occasionally, on only two occasions was it well defined, and then for so short a time that no measure could be obtained. A report is preparing with a view to compare the auroral displays with magnetic disturbance, meteorological changes, and other phenomena which will include the few spectroscopic observations obtained.

J. RAND CAPRON

Guildown, December 24

Insects and Artificial Flowers

IN a late number of NATURE a short account is given of some experiments recently made by Prof. J. Plateau, of Ghent, as to insects being deceived by artificial flowers. The nature of these experiments is not given, but the result would appear to have been of a somewhat negative character. In connection with the subject the following incident will not, I think, be considered uninteresting. I was coming by one of the lake steamers from Como to Menaggio, in September, 1875, and saw a humming-bird hawk moth, *Macroglossa stellatarum*, fly to some bright-coloured flowers on a lady's hat on deck, and hang, poised over them for a short time, and then fly away. During the process it made one of those short familiar darts off, for a moment, and then returned, after the manner of the moth when disturbed, and it remained long enough to convince me that it had tested the flowers and found them wanting. Another incident comes across my mind while writing this, which, though it does not exactly bear upon the point, yet is of a somewhat kindred nature. I was crossing from Harwich to Antwerp in August of the same year, and as the weather was fine, and the boat crowded, I remained on deck all night. About 4 o'clock in the morning I saw what appeared to be a bird or a bat flying rapidly about the rigging. As I was watching it the funnel of the steamer poured forth a thick column of black smoke, owing to the fresh coaling it had just received. Off went the creature as soon as it perceived the change, or, at all events, as soon as the change took place, and flew for some time in and about the smoke, now darting through it, close to the funnel mouth, and then letting itself be borne along with it, for some distance, as if in sport, looking very strange and weirdlike in the process.

---

[1] A table of the mean amounts of oxygen in a hundred parts of oxygen and nitrogen contained in waters from different depths

After awhile, as the full daylight broke, it left the smoky region above and came down towards the deck, and I then discovered it to be neither bird nor bat, but a specimen of the death's-head moth, *Sphinx Atropos*, whose flight I then witnessed for the first time. After running the gauntlet of several of the passengers, who tried to catch it with their hats, it settled somewhere on the spars or woodwork of the boat and escaped, perhaps to renew its flight in a similar manner the following day.

Highfield, Gainsborough, December 21 F. M. BURTON

The Selective Discrimination of Insects

MAY I be permitted to remark on Mr. Bridgman's communication in NATURE (vol. xvii. p. 102)? He says he has collected pollen grains of different kinds washed from the thigh of an *Andrena nigro-ænea*, and varying in colour from orange-red to white. The true inquiry as to the discrimination of insects is not as to the colour on distinct kinds of pollen, but their homogeneity in respect of fertilisation.

The remark I made implied, rather than expressed, that bees and butterflies visited only those plants the admixture of the pollens of which induced fertilisation. In this respect and in this only, it appears to me, the investigation of the subject becomes of importance. No fact of natural phenomena is without use and without instruction; there are *no hap-hazards* in nature. If Mr. Bridgman, or other naturalists, can show the admixture of the diverse grains of pollen collected by him from the thighs of the creature named would not induce the fertilisation of the plants from which they were collected, then the discriminatory fact assumed is dispelled and the peculiarity observed by Mr. Forbes and myself, and doubtless by others, becomes of little value. The colour of the pollen grains is of no importance in the inquiry, as observation shows; the discriminatory fact, if it has any importance, is not as to variations in colour, but the collection of the pollen from distinct species of plants the admixture of which *would not induce fertilisation*. If it be proved that the admixture of the collected pollens are only such as induce fertilisation, then a natural phenomenon is disclosed of great importance. This is the fact I imagine Sir John Lubbock meant when he advised the pursuit of the inquiry.

I am still of opinion that it is *odour*, not colour, which is the attractive element. It is so with carrion birds and the blow-flies which collect on the fœtid arum. In phenomena one particular law appears to be repeated in all the natural kingdoms. The same rule is also to be observed in physics. S. B.

Sunbury-on-Thames

OUR ASTRONOMICAL COLUMN

THE TOTAL SOLAR ECLIPSE OF A.D. 418, JULY 19.—Philostorgius, in his "Epitome of Ecclesiastical History," relates that while Theodosius the Second was a youth, on July 19, at the eighth hour of the day, the sun was so greatly eclipsed that the stars were seen, and while the sun was thus hidden there was seen in the sky a light in the form of a cone, "which some ignorant people called a comet"; and he goes on to describe the supposed differences in the appearance of the phenomenon from that of a comet, particularly remarking that it resembled the flame of a torch, subsisting of itself, without any star to serve as a base, and adding particulars of its track and duration. That the object thus singularly discovered during a total, or nearly total, eclipse of the sun, was really a comet as the "ignorant people" supposed, is proved by the records in the Chinese Annals. The eclipse to which reference is made by Philostorgius took place on July 19, A.D. 418. The comet of that year is stated in Pingré's *Cometographie* to have been discovered in the 10th moon, commencing November 15, in which he follows the Jesuit, Couplet, but the account given by Mr. Williams, on the authority of the She Ke and Ma Twan Lin, dates the appearance of the comet on day Kang Tsze of the 5th moon, when it was situate in Ursa Major; on September 15 it was on the confines of Leo and Virgo; "it was bright, and gradually lengthened until it was 100 cubits in length." Philostorgius also refers to the passage of the comet through Ursa Major, and says it continued visible until the end of the autumn.

It may interest some readers to have particulars of the eclipse, during which it is recorded that a large comet was first discovered. The following figures depend upon a very similar system of calculation to that applied to other ancient eclipses, described in this column:—

G.M.T. of Conjunction in R.A. 418, July 18, at 23h. 3m. 17s.

	°	′	″	
Right Ascension	118	30	48	
Moon's hourly motion in R.A.		38	34	
Sun's ,, ,, ,, ...		2	32	
Moon's declination	21	23	10	N.
Sun's ,, ...	21	2	41	N.
Moon's hourly motion in decl.		3	40	S.
Sun's ,, ,, ,, ...		0	28	S.
Moon's horizontal parallax		59	38	
Sun's ,, ,, ...		0	9	
Moon's true semi-diameter		16	15	
Sun's ,, ,, ...		15	48	

At Constantinople these elements give a very large eclipse, commencing at 0h. 5m. and ending at 2h. 50m. local mean time, magnitude, 0·95; at a short distance to the south the eclipse would be total.

VARIABLE STARS.—The following are geocentric minima of Algol and S. Cancri during the ensuing two months, so far as they are visible in this country. They are expressed in Greenwich mean time, and are calculated from Prof. Schönfeld's elements:—

ALGOL.

ASTRONOMICAL PHENOMENA IN 1878.—The principal astronomical occurrence of the next year is the total solar eclipse of July 29, which traverses British Columbia and the United States; the American astronomers will doubtless give a good account of it, and it is reported they are likely to have coadjutors from this side of the Atlantic. There will be a transit of the planet Mercury on May 6, visible in this country to past the time of the nearest approach of centres, and a lunar eclipse on August 12, magnitude 0·6, wholly visible here. Mars will be occulted by the moon on the evening of June 3, and the second-magnitude star σ Sagittarii on the afternoon of October 30; on November 10 the moon traverses the Pleiades. A return of Encke's comet to perihelion also takes place in the summer, but not under favourable circumstances for observation, and the comet of short period detected by Tempel on July 3, 1873, will again arrive at perihelion late in the spring. Saturn's rings disappear on February 6, but reappear on March 1, according to Bessel's elements.

FERTILISATION OF GLOSSOSTIGMA

THE following letter to Mr. Darwin has been forwarded to us by him for publication:—

"Museum, Auckland, October 23, 1877

"My Dear Sir,—I forward to you a copy of a paper on the fertilisation of *Selliera*, one of the *Goodeniaceæ*, which perhaps you may care to glance over. When I wrote it I did not know of your notes on *Leschenaultia*, published in the *Gardener's Chronicle* for 1871. In both plants the pollen is shed before the expansion of the flower, and neatly collected in the indusium, but in *Selliera* the stigma is situated within the indusium, and by its gradual upward growth after the flower expands slowly forces out the pollen, which is then transferred by insects to older flowers. When mature, the stigma protrudes considerably beyond the indusium. This appears to differ entirely from what takes place in *Leschenaultia*.

"I have recently been much interested with the curious irritability displayed by the stigma of *Glossostigma elatinoides*, one of the Scrophularineæ. The style is dilated towards its apex into a broad spoon-shaped stigma, which, when the flower expands, is closely doubled over the four stamens, entirely concealing them from view. If the front of the bent part of the style is touched it at once springs up, uncovering the stamens, and moves back to the upper lobe of the corolla, to which it becomes closely applied. In this position it remains for a few minutes, and then slowly moves back to the stamens and curves over them as at first. It appears to me that this irritability of the stigma is simply a contrivance to insure cross-fertilisation, for an insect crawling into the flower must inevitably touch the stigma, which would then uncover the stamens. On withdrawing, the insect would be certain to dust itself with pollen, but it would not by this effect the fertilisation of the flower, for the stigma would be then closely applied to the upper lobe of the corolla, entirely out of its way. If the insect were, however, to visit another flower it is evident that it must come into contact with the stigma at its first entrance and would doubtless leave some pollen thereon. The movement of the stigma is remarkably rapid, and its apex must pass through an angle of at least 180°. I have been unable to find a record of a similar case, or of so pronounced a degree of irritability in the stigma of any plant. The movement of the lobes of the stigma in *Mimulus* is much weaker, and is through a much less angle. Yours faithfully,

"T. F. CHEESEMAN

"Charles Darwin Esq., F.R.S."

A TELEPHONIC ALARUM

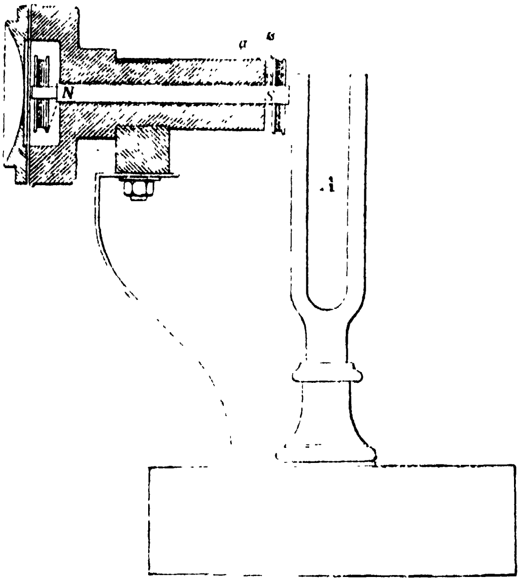
THE speaking of the telephone is admittedly so weak that it can only be caught by keeping the instrument in immediate contact with the ear. Hence there is transmitted through the telephone in its present form no sound which would be intense enough to announce to any one who was in a large room and who did not hold the telephone close to his ear, that a message was about to be sent from the transmitting station. The consequence is that a warning apparatus must be attached to the telephone, so that there may be no fear of missing a projected telephonic conversation.

It is clear that the conducting wire of a telephone can be used to sound a bell as an alarum by means of a current from a galvanic battery, and thereby the defect referred to would be supplied. But the necessary apparatus would considerably raise the price of fitting up a telephone apparatus, and besides, one most important property of the telephone, viz., producing the required electric current automatically, would be partly lost. I have, then, invented another warning apparatus, which, I believe, is quite workable.

Hitherto telephones have been so constructed that only one pole (N in the figure) of the magnet is effective; I now use also the second pole S, by providing it with a coil of wire, which is simply inserted in the circuit behind the first coil. (The dotted lines in the figure will explain this connection; the two ends *a* and *β* are connected with the binding screws fastened to the telephone; from this the circuit goes to the second telephone.) Before this pole of the magnet may be very easily set up a tuning-fork, A, which, with the telephone, is simply fixed on a resonance case, B; this arrangement should be made both at the transmitting and receiving stations, and both forks should be in unison. If now the sending station wish to signal that a conversation is to be begun, the fork of that place will be sounded with a fiddle-bow; the currents thereby induced in the coil are powerful enough to set the fork of the receiving station in such intense vibration that the sound may be distinctly heard in a large room; warned by this signal a person can in the usual way put the telephone to his ear and listen to the words from the transmitting station. And so *vice versâ*.

I have made an experiment in a large room, when about 100 people were present, and all could hear the sounds of the fork, which in the manner described was set in vibration by a second fork in a distant room. The two forks were König Ut_4; lower forks give less clearly heard tones; with higher forks I was unable to make any experiment, since I had not two similar ones at my disposal.

Let me mention two other experiments which I have made. The first is of importance in connection with the question as to how the clang-tints of tones are reproduced through the telephone. In one of the two telephones described substitute for the Ut_4 fork a higher one, and sound this by means of a fiddle-bow, and there will be heard with another inserted telephone of the ordinary construction tones of even 12,000 double vibrations per second, a sign that the variations of the magnetic condition of a magnet perceptibly occur, even when the forces producing these variations change their size 24,000 times in a second. This result moreover was not to be expected, since, as is known, magnetic polarisation requires time to accomplish. Whether these higher tones are comparatively weaker than the deeper cannot be determined, but probably this is the case.



In another experiment I used the telephone to test the electric vibrations indicated by Helmholtz and others, which are produced by the opening of the primary current of an induction apparatus in the induced coil, when the ends of the latter are connected with the armatures of a condenser. For this purpose I inserted the telephone in the circuit between coil and condenser, and observed the effect when the current in the inducing spiral was opened.

When the ends of the induced spiral were not connected with the condenser, I heard a dull report in the telephone; when, again, these ends were connected with the condenser, this report was accompanied by a shorter, higher sound, whose vibration-number might perhaps be determined by a musical ear; a proof of the existence of the vibrations mentioned in the last case. The observations were made with a telephone, the iron membrane of which was very thin and had a very deep tone.

W. C. RÖNTGEN

THE NEW PARIS TRANSIT CIRCLE[1]

OF the numerous instruments with which Leverrier enriched the Paris Observatory during the twenty years of his direction, the last which he was able to see completely installed was the new transit circle. This instrument was not, like all the others, constructed at the expense of the State; an inscription on the marble pillars that support it informs the visitor that it was presented to the Observatory by the generous munificence of M. Raphaël Bischoffsheim. This is not the only gift of M. Bischoffsheim to astronomy; the Observatory of Lyons is also indebted to him for its fundamental instrument.

The project of erecting a new meridian circle at the observatory goes back to the time of the debate raised before the Academy of Sciences on the subject of the transfer of the observatory to a site outside Paris. Those who would not admit the legitimacy of the complaints made by the adversaries of the present situation of the observatory, were obliged to admit that the great meridian room, constructed in 1830 by Arago, did not offer any of the guarantees necessary to observations of great precision. The thickness of the walls and of the double roof of that room, the small breadth of the openings, the nearness of the observatory buildings, the difference of level between the two faces north and south, must necessarily affect the equilibrium of the neighbouring layers of the atmosphere and hinder them from taking that horizontality which admits of the correction of the observations from the influence of refraction.

Since the astronomer cannot get rid of this troublesome influence, his first business ought then to be to reduce it to conditions in which it may be possible to calculate the effect. Thus what strikes the visitor admitted to the new meridian circle of the Observatory is the small building in which it is placed. In the middle of a green lawn rises a hut made entirely of sheet-iron, the roof formed of two plates which, by sliding upon rollers, may be separated from each other, and leave all the upper part of the building open. The walls are formed of two envelopes of thin iron, between which the air freely circulates, thus maintaining the whole structure at the temperature of the air itself. Large windows may also be opened, and the observer and the instrument be thus placed in the same conditions as if the observations were made in the open air. All these conditions are to avoid as far as possible the disturbances arising from atmospheric refraction, the greatest source of inaccuracy in astronomical observation. The only obstacle which may yet be a hindrance to perfection in the conditions of observation is the presence of those beautiful trees which make the terrace of the observatory a magnificent garden, but which store up the warm air during the day and slowly distribute it during the night. No doubt some day the astronomers will be obliged to sacrifice to the precision of their observations the enjoyment of this beautiful foliage.

The meridian circle is composed, as its name indicates, of two instruments: the meridian telescope, intended, by its association with an astronomical clock, to fix the moment of the passage of a star across the meridian of the place of observation, and the mural circle, which gives the measure of the angular distance of this same star from the pole or the zenith. When, forty years ago, Gambey constructed the two meridian instruments of the Paris Observatory, so justly celebrated and on the model of which those of most other observatories have been designed, he had to reconcile, by prodigies of skill, the lightness resulting from the means of construction then in use, with the rigidity of the parts necessary for precision of observation. It is the alliance of these two almost contradictory qualities which renders so interesting the instruments of that celebrated artist and especially his machine for dividing the circles, which the Baron Séguier has restored in the galleries of the Conservatoire. But there resulted from this at first the necessity of separating the measure of the two co ordinates of the stars—the instant of the meridian passage and the polar distance. There also resulted the necessity which Gambey was under to fix on his mural circle of two metres in diameter, a telescope altogether insufficient in optical power.

A simple glance at the great meridian circle of the observatory, the western equatorial, the great telescope, the new instrument of M. Bischoffsheim, all from the workshop of the great mechanician, M. Eichens, shows the revolution which has been effected in the processes of construction. In place of instruments formed of pieces of sheet brass connected by simple screws or even soldered together, we have the bodies of the telescope of cast-iron bolted on axes of cast-iron and steel, strong and elegant in appearance; circles of bronze cast in a single piece and protected against all deformation by numerous cross-bars. It is the art of the engineer applied to the construction of astronomical instruments, with the power given by the choice of metals and the thickness of pieces, and the precision which the employment of engineering tools secures.

This revolution was begun in England about 1847 by the Astronomer-Royal, Sir George Airy. In 1863, M. Leverrier successfully installed a meridian circle greater still than that of Greenwich, and intended, like it, for the observation of the small planets. But these gigantic instruments, veritable siege-guns of long range, since they reach the farthest depths of the heavens, want, simply on account of their weight, one essential quality—they are not reversible. Whatever be the rigidity of the pieces, the instrument is subject, in each successive position, to flexions necessarily unequal, which the astronomer must investigate and measure in order to correct his observations. But this investigation and this measurement can only be made by turning round the instrument. It will be understood, in fact, that the apparatus, directed successively to the same point of the sky, first with one of its faces up, then the same face below, gives, if it is really perfectly rigid but elastic, two results differing equally from the truth, one *minus* and the other *plus*, so that the mean of the two observations gives the exact position of the star. It is this which may be expected from the new meridian circle of M. Bischoffsheim. Fig. 1 represents the telescope upon its car, which serves to raise it above its pillars and to turn it right round by a movement of rotation around a vertical axis.

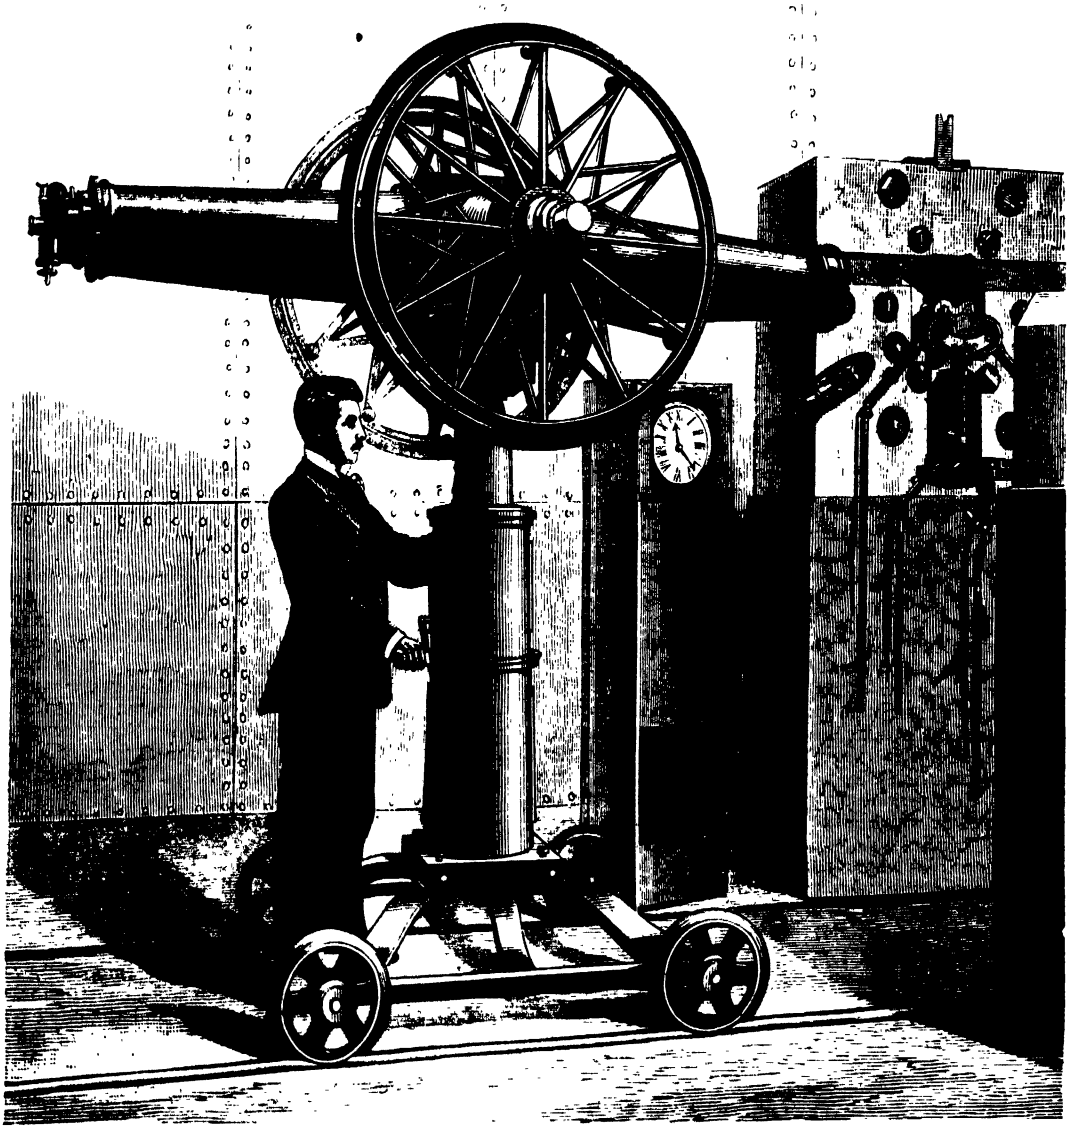
Since 1852 M. Brunner has constructed small portable instruments answering to these conditions. Improved by his sons, by M. Rigaud, and by M. Eichens, these meridian circles are now only used in geodesic expeditions. In 1868 M. Eichens constructed for the observatory of Lima a reversible meridian circle, the telescope of which was 2·30 m. in length, and the object-glass 20 cm. in free opening. It is this model, successively improved, which has become, in the hands of the able constructor, the meridian circle of Marseilles (1876), and the circle given by M. Bischoffsheim (1877). The object-glass of the first was made by Léon Foucault, the two others are by M. Ad. Martin. The new observatory of Lyons, in the establishment of which M. André took an active part energetically sustained by the Administration, will soon possess a similar meridian circle, a little smaller (telescope of 2 m., object-glass of 14 cm. aperture, by M. Praczmowzki), the expense of which is borne by M. Bischoffsheim.

The illustrations which we give then show the perfected model meridian circle employed in observatories for the determination of the celestial co-ordinates of the stars. To be able to understand the use of the various parts of the instrument, it will suffice to describe a complete observation of a star.

Some minutes before the passage of the star across the meridian, the astronomer gives to the telescope such an inclination that the star, carried on by the daily movement, will cross the field of the instrument. For this purpose the interior circles fixed on the axis of the telescope carry a rough scale which may be seen by means of a pointer telescope fixed on the east wall. A clamp which clasps the edge of this circle serves to fix the instrument. The observer then places himself on the observing chair in the position indicated on Fig. 2. The star soon appears, enters the field of view on the west and proceeds towards the east side. With the star the observer sees in the field of view a network of spider threads stretched vertically and traversed by a horizontal thread. Listening to the beats of the clock, he notes the second and the fraction of a second at which the star passes under each of the vertical threads; the mean of these times is the precise moment of the passage across the middle thread. At this same moment he slightly displaces the telescope by a movement given to the clamp and brings the star under the horizontal thread. The direction of a line determined by the crossing of this thread and the middle vertical one and the optical centre of the object-glass is that along which the star is seen at the moment of its passage across the middle thread. To fix this direction it is necessary to connect it with two points of an absolute fixity. For this purpose the telescope is provided with a circle of a metre in diameter, the limb of which is very finely and very exactly divided; this turns with the telescope in front of six microscopes permanently fixed to the east pillar. M. Eichens has adopted for these microscopes the arrangement devised by Sir George Airy for the meridian circle of Greenwich. The tube of each of these is formed by the side of a hole pierced in the block of marble which forms the upper part of the pillar; the positions of these microscopes is then permanently fixed to that of the wall,

---

[1] From an article in *La Nature* by M. C. Wolf.



ing Apparatus.

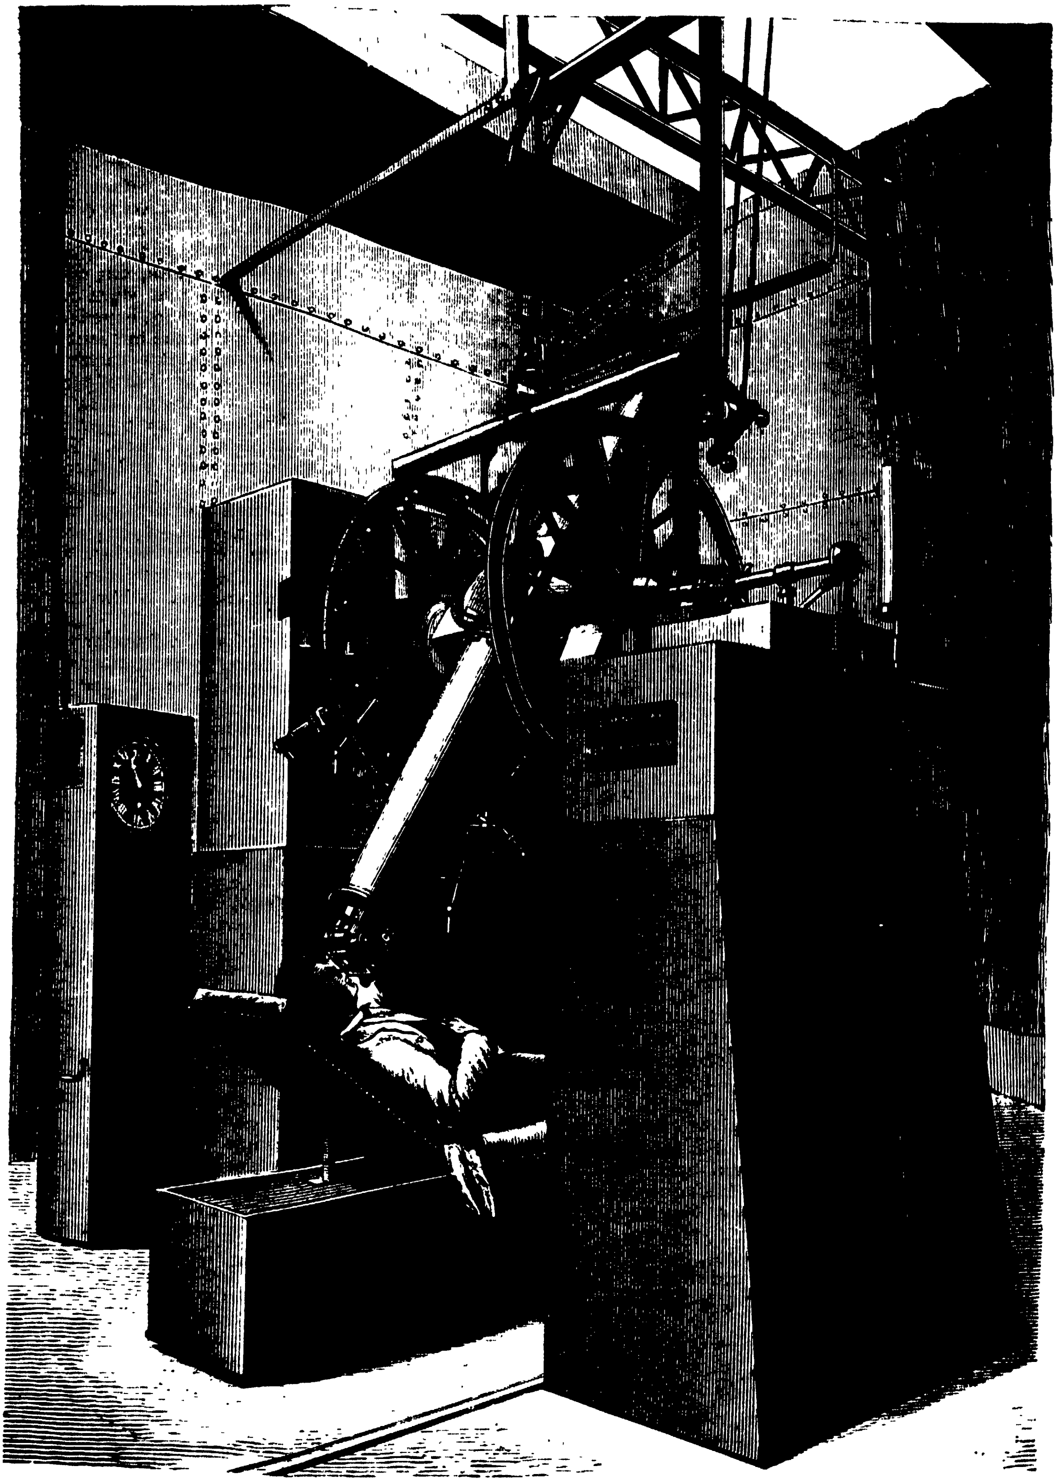


FIG. 2.—Taking an Observation.

and can only change by a displacement of the wall itself. Other orifices admit to the circle the light of a lamp and enable the divisions to be read. These are drawn at every five minutes of the circle, which then bears 4.320 equidistant marks; each microscope is provided with a micrometer which enables the tenths of a second of arc to be observed.

If now, by observations of the pole star at its upper and lower transits, the observer determines in the same way the direction of the telescope looking to the pole, the angle comprised between that direction and that of the telescope directed to the star will give the polar distance of the star. If by means of a mercury bath he determines the direction of the telescope when its optical axis is vertical, he will ascertain in the same way the distance of the star from the zenith.

These observations may be made in the two positions which the telescope takes before and after being turned round. This is why it carries two cast-iron circles roughly graduated and two brass circles finely graduated on silver, which on the reversal of the instrument are substituted for each other before the pointer-telescope and the fixed microscopes. The arrangement of these circles insures a perfect symmetry to the instrument, an essential condition if we wish to prevent irregular deformations.

But these operations will only give the co-ordinates of the star if they are made with an instrument set in the meridian of the place. It is necessary then that the telescope should turn round a horizontal axis, that it should be perpendicular to that axis, and that the plane which it describes in turning should pass through the pole of the earth. A level, which the illustration represents resting by two forks upon the pivots of the telescope, but which during the observations is raised by means of a crane fixed to the ceiling, serves to measure and correct the inclination of the axis of rotation. By turning it upon a long support the perpendicularity of the optical axis on the axis of the pivots can be assured. Two supports are to be constructed, one on the north, the other on the south; the latter only has been made. Finally the astronomical observation of the pole star indicate if the last of the three conditions is fulfilled.

A word on the illumination of the system of cross wires visible in the eye-piece. During the day they stand out on the clear background of the sky; at night the same effect is obtained by means of a ray of light proceeding from a gas-lamp fixed on the west pillar, the rays of which are sent towards the eye-piece by a small prism fixed in the middle of the telescope. A screen with a variable opening, or cat's-eye, permits the intensity of the light to be proportioned to the brightness of the star observed. Finally, for very weak stars a very simple mechanical arrangement suppresses all light in the field, and brings it to bear on the wires, which appear as luminous lines on a background absolutely dark.

The long illness of M. Leverrier did not permit him to push on, so actively as he would have wished, the preliminary investigations of this beautiful instrument, among which we must mention one, long and difficult—the divisions of the two circles. It will, without doubt, be facilitated by this circumstance, that, traced by means of the dividing machine constructed by M. Eichens, the lines present a regularity and a finish altogether favourable to precision.

The astronomers of the observatory will hold it a point of honour to take advantage as soon as possible of the magnificent apparatus which they owe to the generosity of M. Bischoffsheim.

FETICHISM IN ANIMALS

MR. HERBERT SPENCER, in his recently published work on the "Principles of Sociology," treats of the above subject. He says: "I believe M. Comte expressed the opinion that fetichistic conceptions are formed by the higher animals. Holding, as I have given reasons for doing, that fetichism is not original but derived, I cannot, of course, coincide in this view. Nevertheless, I think the behaviour of intelligent animals elucidates the genesis of it. I have myself witnessed, in dogs, two illustrative cases" One of these cases consisted in a large dog, which, while playing with a stick, accidentally thrust one end of it against his palate, when, "giving a yelp, he dropped the stick, rushed to a distance from it, and betrayed a consternation which was particularly laughable in so ferocious-looking a creature. Only after cautious approaches and much hesitation was he induced again to lay hold of the stick. This behaviour showed very clearly the fact that the stick, while displaying none but the properties he was familiar with, was not regarded by him as an active agent, but that when it suddenly inflicted a pain in a way never before experienced from an inanimate object, he was led for the moment to class it with animate objects, and to regard it as capable of again doing him injury. Similarly in the mind of the primitive man, knowing scarcely more of natural causation than a dog, the anomalous behaviour of an object previously classed as inanimate, suggests animation. The idea of voluntary action is made nascent; and there arises a tendency to regard the object with alarm, lest it should act in some other unexpected and perhaps mischievous way. The vague notion of animation thus aroused will obviously become a more definite notion, as fast as development of the ghost-theory furnishes a specific agency to which the anomalous behaviour can be ascribed."

The other case observed by Mr. Spencer was that of an intelligent retriever. Being by her duties as a retriever led to associate the fetching of game with the pleasure of the person to whom she brought it, this had become in her mind an act of propitiation; and so, "after wagging her tail and grinning, she would perform this act of propitiation as nearly as practicable in the absence of a dead bird. Seeking about, she would pick up a dead leaf or other small object, and would bring it with renewed manifestations of friendliness. Some kindred state of mind it is which, I believe, prompts the savage to certain fetichistic observances of an anomalous kind."

These observations remind me of several experiments which I made some years ago on this subject, and which are perhaps worth publishing. I was led to make the experiments by reading the instance given in the "Descent of Man," of the large dog which Mr. Darwin observed to bark at a parasol as it was moved along a lawn by the wind—so presenting the appearance of animation. The dog on which I experimented was a Skye terrier—a remarkably intelligent animal, whose psychological faculties have already formed the subject of several communications to this and other periodicals.[1] As all my experiments yielded the same results I will only mention one. The terrier in question, like many other dogs, used to play with dry bones by tossing them in the air, throwing them to a distance, and generally giving them the appearance of animation, in order to give himself the ideal pleasure of worrying them. On one occasion, therefore, I tied a long and fine thread to a dry bone and gave him the latter to play with. After he had tossed it about for a short time I took an opportunity when it had fallen at a distance from him and while he was following it up, of gently drawing it away from him by means of the long and invisible thread. Instantly his whole demeanour changed. The bone which he had previously pretended to be alive now began to look as if it really were alive, and his astonishment knew no bounds. He first approached it with nervous caution, as Mr. Spencer describes, but as the slow receding motion continued, and he became quite certain that the movement could not be accounted for by any residuum of the force which he had himself communicated, his astonishment developed into dread, and he ran to conceal himself under some articles of furniture, there to behold at a distance the "uncanny" spectacle of a dry bone coming to life.

---

[1] See especially an article on "Conscience in Animals," in *Quarterly Journal of Science* for April, 1876.

Now in this, and in all my other experiments, I have no doubt that the behaviour of the terrier arose from his *sense of the mysterious*, for he was of a highly pugnacious disposition, and never hesitated to fight an animal of any size or ferocity; but apparent symptoms of spontaneity in an inanimate object which he knew so well, gave rise to feelings of awe and horror which quite enervated him. And that there was nothing *fetichistic* in these feelings may be safely concluded if we reflect, with Mr. Spencer, that the dog's knowledge of causation, for all immediate purposes, being quite as correct and no less stereotyped than is that of "primitive man," when an object of a class which he knew from uniform past experience to be inanimate suddenly began to move, he must have felt the same oppressive and alarming sense of the mysterious which uncultured persons feel under similar circumstances. But further, in the case of this terrier we are not left with *à priori* inferences alone to settle this point, for another experiment proved that the sense of the mysterious was in this animal sufficiently strong of itself to account for his behaviour. Taking him into a carpeted room I blew a soap-bubble, and by means of a fitful draught made it intermittently glide along the floor. He became at once intensely interested, but seemed unable to decide whether or not the filmy object was alive. At first he was very cautious and followed it only at a distance, but as I encouraged him to examine the bubble more closely, he approached it with ears erect and tail down, evidently with much misgiving; and the moment it happened to move he again retreated. After a time, however, during which I always kept at least one bubble on the carpet, he began to gain more courage, and the scientific spirit overcoming his sense of the mysterious, he eventually became bold enough slowly to approach one of the bubbles and nervously to touch it with his paw. The bubble, of course, immediately vanished; and I certainly never saw astonishment more strongly depicted. On then blowing another bubble, I could not persuade him to approach it for a good while; but at last he came and carefully extended his paw as before with the same result. But after this second trial nothing would induce him again to approach a bubble, and on pressing him he ran out of the room, which no coaxing would persuade him to re-enter.

One other example will suffice to show how strongly developed was the sense of the mysterious in this animal. When alone with him in a room I once purposely tried the effect on him of making a series of horrible grimaces. At first he thought I was only making fun; but as I persistently disregarded his caresses and whining while I continued unnaturally to distort my features, he became alarmed and slunk away under some furniture, shivering like a frightened child. He remained in this condition till some other member of the family happened to enter the room, when he emerged from his hiding-place in great joy at seeing me again in my right mind. In this experiment, of course, I refrained from making any sounds or gesticulations, lest he might think I was angry. His actions, therefore, can only be explained by his horrified surprise at my apparently irrational behaviour—*i.e.*, by the violation of his ideas of uniformity in matters psychological. It must be added, however, that I have tried the same experiment on less intelligent and less sensitive terriers with no other effect than causing them to bark at me.

I will only add that I believe the sense of the mysterious to be the cause of the dread which many animals show of *thunder*. I am led to think this, because I once had a setter which never heard thunder till he was eighteen months old, and on then first hearing it I thought he was about to die of fright, as I have seen other animals do under various circumstances. And so strong was the impression which his extreme terror left behind, that whenever afterwards he heard the boom of distant artillery practice, mistaking it for thunder, he became a pitiable object to look at, and, if out shooting, would immediately bolt home—or, if at a great distance from home, would endeavour to bury himself. After having heard real thunder on two or three subsequent occasions, his dread of the distant cannons became greater than ever; so that eventually, though he keenly enjoyed sport, nothing would induce him to leave his kennel, lest the practice might begin when he was at a distance from home. But the keeper, who had a large experience in the training of dogs, assured me that if I allowed this one to be taken to the battery, in order that he might learn the true cause of the thunder-like noise, he would again become serviceable in the field. The animal, however, died before the experiment was made.

GEORGE J. ROMANES

RUHMKORFF

WE regret to record the sudden death on December 20, at Paris, of Henry Daniel Ruhmkorff, whose name is so closely connected with the history of magneto-electricity. He was born in Hanover, Germany, in 1803, and but little is known of his early life. In 1819 he wandered to Paris, and obtained a position as porter in the laboratory of Prof. Charles Chevalier, at that time one of the leading French physicists. Here he displayed a remarkable fondness for electrical apparatus, as well as ingenuity in its arrangement, and was enabled shortly after to start a modest manufactory of physical apparatus. Through the efforts of Chevalier and the excellence of the work performed, the business was rapidly extended. In 1844 Ruhmkorff brought out his first invention, a convenient thermo-electric battery. Soon after he turned his attention to magneto-electricity, especially the production of the induced currents, discovered by Faraday in 1832. A long series of experiments resulted in the appearance, in 1851, of the famous "Ruhmkorff coil," with its later modifications, the most important piece of apparatus in this branch of physics. With this powerful adjunct the electrician was enabled to obtain sparks 18 inches in length, pierce thick plates of glass, and carry out a vast variety of experiments. The invention was rewarded by a decoration and medal at the Exhibition of 1855, while in 1858 it received the first prize of 50,000 francs at the French Exhibition of Electrical Apparatus. Since then the manufacture of the coils and of electrical machines in general has assumed enormous dimensions, and the leading physicists of Europe are well acquainted with the dingy little bureau in the Rue Champollion, near the University. Personally M. Ruhmkorff was of a quiet, dignified appearance, and despite the disadvantages of his early life, he enjoyed the friendship of the leading Parisian *savants*, and was an honoured member of the French Physical Society. M. Jamin delivered an address over the grave, in which he stated that Ruhmkorff died almost a poor man, because he had spent all his earnings on behalf of science and in works of benevolence.

LIQUEFACTION OF OXYGEN

THE number of the permanent gases is rapidly diminishing. We have had occasion recently to refer to M. Cailletet's successful attempts to compress nitric oxide, N_2O_2, methyl hydride, CH_4, and acetylene, C_2H_2, to the liquid form. The list of non-compressible gases was thus reduced to three, viz., hydrogen, nitrogen, and oxygen. Within the past week M. Raoul Pictet has succeeded in obtaining the last-mentioned gas in the liquid state, an event which is certainly one of the most novel and interesting in the chemical progress of the expiring year.

The *Journal de Genève* of December 23] gives the following account of the experiments:—

One of the most interesting physical experiments of our time has just been made at Geneva with rare success in the laboratory of the Society for the Manufacture of Physical Instruments. M. Raoul Pictet has succeeded in obtaining, by means of ingeniously combined apparatus, the liquefaction of oxygen gas. The following is the process by which the curious result was obtained:—

By a double circulation of sulphurous acid and carbonic acid, the latter gas is liquefied at a temperature of 65° of cold, under a pressure of from four to six atmospheres. The liquefied carbonic acid is conducted into a tube four metres long; two combined pumps produce a barometric vacuum over the acid which is solidified in consequence of the difference of pressure. Into the interior of this first tube containing solidified carbonic acid is passed a tube of a slightly less diameter, in which circulates a current of oxygen produced in a generator containing chlorate of potash and the form of which is that of a large shell thick enough to prevent all danger of explosion. The pressure may thus be carried to 800 atmospheres.

Yesterday morning (December 22), all the apparatus being arranged as described, and under a pressure which did not exceed 300 atmospheres, a liquid jet of oxygen issued from the extremity of the tube, at the moment when this compressed and refrigerated gas passed from that high pressure to the pressure of the atmosphere.

The great scientific interest of this experiment is that it demonstrates experimentally the truth of the mechanical theory of heat, by establishing that all gases are vapours capable of passing through the three states—solid, liquid, and gaseous. Only twenty days ago M. Cailletet, as we have said, succeeded in liquefying the bioxide of nitrogen, under a pressure of 146 atmospheres and at a temperature of 11° of cold. After the experiment of M. Raoul Pictet there remain not more than two elemental gases which have hitherto escaped the attempt at liquefaction—hydrogen and nitrogen.

The experiment above described was to be repeated on Monday and subsequent days, with some slight changes in the processes and the arrangement of the apparatus.

NOTES

SOME interesting experiments with the telephone have been made by Mr. W. H. Preece between Dublin and Holyhead through the submarine cable. Conversation was freely maintained and songs were sung on each side and heard and appreciated on the other. The articulation was excellent, but muffled, as though the speakers spoke through respirators. This is what might have been expected from the static induction of the cable. It is the longest actual cable yet spoken through, its length being sixty-seven miles.

AT their last sitting the enlarged Council of the Paris Observatory were occupied in considering the question of the position of French meteorology. 'M. Dumesnil, the representative of the minister, was obliged to silence some members of the minority who were assailing the character of some of the physicists having the control of the Observatory and the transmission of the warnings to the sea-ports. A large majority rendering justice to the ingenuity displayed and to the highly scientific nature of the warnings, passed a vote recommending the administration not to alter the present condition of things at the Observatory.

DR. CARLO GHINOZZI, Professor of Medical Clinic at the Istituto Superiore of Florence, for many years colleague and afterwards successor of Prof. Bufalini, died on Saturday, the 15th instant, at the age of 66 years.

IN Bonn a committee has been formed consisting of leading citizens and Professors Bauerband, Kekulé, and Proschel, of the University, for the purpose of erecting a monument to the late Prof. Jacob Noeggerath, whose death last September we briefly alluded to at the time. Prof. Noeggerath was born in Bonn October 10, 1788, and since the foundation of the university in 1818 had been connected with it as Professor of Mineralogy. As a successful teacher of the natural sciences he acquired an unusually widespread fame, and the majority of the present Prussian mining officials pursued their studies under his direction. His general scientific researches touch on a number of interesting geological questions, such as the formation of basalt, &c.; but his chief efforts were directed to an exhaustive study of the mineralogy and geology of Rhenish Westphalia, the results of which are to be seen in the magnificent mineralogical collection at Bonn, and the rapid development of the mining interests in this district. As a favourite writer of popular works on scientific subjects, he contributed in no small degree to the general taste for this class of literature now prevalent in Germany.

THE expedition sent out by the Dutch Geographical Society for the exploration of Sumatra has met with a severe check by the sudden death of its leader, M. Schouw Landvort. His extensive knowledge, indomitable perseverance, and great powers of endurance, fitted him eminently for the position, these qualitie being notably evidenced by the bold journey across the middle of the island, through hitherto unknown regions, in the company of natives only, which we had occasion lately to chronicle.

AT the meeting of the Council of the Zoological Society on Wednesday last week, the president, the Marquis of Tweeddale, proposed that the silver medal of the Society should be awarded to Mr. Robert Hudson, F.R.S., in acknowledgment of the valuable services he had rendered to the Society for the fifty years that he had been a Fellow thereof. The motion was carried unanimously at the full meeting of the Council.

THE organisation of public instruction in France is undergoing an exceedingly beneficial change. A decree, published in the *Journal Officiel* of December 17, establishes a representative Council of Public Instruction under the title of "Comité Consultatif." The committee is divided into three different sections corresponding to the three divisions of public instruction in France, primary, secondary (grammar schools), and superior (universities). Each section is to appoint its president and secretary. The three sections in general session are to be presided over by the minister. Some of the members are appointed by the minister to serve during a period of five years, others are members *ex officio*. The minister cannot elect any who are not members of the teaching body or of the Institut. The directors of the administration of primary, secondary, or superior instruction are *ex officio* members of their respective sections. They meet yearly at a certain fixed period. The opinion of the committee is not binding, but it must be taken on a number of matters, such as bills which are to be presented to Parliament, modification of programmes, &c. Another decree appoints the members of the three committees. Among these are many names well-known to science, as MM. Laboulaye, Würtz, Claude Bernard, Vulpian, Gavarret, Chevreul, Faye, Berthelot, Milne-Edwards, Puiseux, and Desains.

THE following are the probable arrangements for the Friday Evening Meetings at the Royal Institution, before Easter, 1878:—January 25, Prof. Huxley, F.R.S., "William Harvey;" February 1, Wm. Henry Preece, C.E., "The Telephone;" February 8, Matthew Arnold, "Equality;" February 15, P. L. Sclater, F.R.S., "Zoological Distribution and some of its Difficulties;" February 22, Prof. Roscoe, F.R.S.; March 1, Richard Liebreich, M.D., "The Deterioration of Oil Paintings;" March 8, Prof. Goldwin Smith, "The Influence of

VOLCANIC eruptions are threatening Iceland again. The last number of the *Skuld*, published in Eskifjödur, states that on the evening previous an unprecedented heat was suddenly felt, so strong that the inhabitants thought themselves in the vicinity of a vast conflagration. The phenomenon was followed by alternate gusts of rain and showers of volcanic ashes accompanied by subterranean rumblings.

THE German Government has lately named a new steamer after the well-known meteorologist, Prof. Dove, of Berlin, in recognition of the advantages accruing to navigation from his many observations and discoveries.

THE Italian Geographical Society has received news from Signori Martini and Cecchi, who have penetrated into Shoa. There is no intelligence of the Marquess Antinori and the engineer Chiarini, whose fate causes grave anxiety.

THE Geographical Society of Paris held a banquet last Saturday to commemorate the fifty-seventh anniversary of its foundation. Among the toasts which were given we must notice that of Mr. Gordon Bennett, the enterprising director of the *New York Herald*, who originated Stanley's fruitful mission, and the King of the Belgians, by MM. Levasseur and de Lesseps.

NEW halls of exhibition for antiquities have been opened in the Louvre. An interesting anthropological exhibition will be opened on January 15 at the Palais de l'Industrie. It will be confined to the discoveries made in South America by the several scientific missionaries sent to that region by the French government. The exhibition will be open only till March 1.

WE have received from Messrs. De la Rue and Co. some specimens of their exquisitely-printed Indelible Diaries, Pocket Diaries, Memorandum Books, and Calendars for the coming year. Our readers have doubtless already supplied themselves with one or other of these. If not, the following statement will recommend the Pocket Diary to every lover of science :—We not only find everything that one finds generally in such a pocket companion, but, under the careful editorship of Mr. Godward, the amateur astronomer is supplied with information as to astronomical phenomena, including the times of rising, southing, and setting of the five principal planets, and the illuminated discs of Venus and Mars, and occultations visible at Greenwich. The physiographer finds meteorological averages of mean temperature, rainfall, and barometer, hints as to weather forecasts, and the magnetic elements. Physical data are not forgotten, and the conversion of metric measures into British inches and centigrade readings into Fahrenheit are given. The geographer and statistician have also facts stored up for them which will certainly be often referred to in the course of the 8,000 odd hours which make up the year. One thing, and one thing only, we miss—the old three-page article and exquisite steel engraving which brought home to everybody the latest thing of mark in the progress of the sciences of observation.

WE learn with pleasure in perusing the last pamphlets sent to us by Capt. Howgate on his intended Polar Colony, that the use of small pilot balloons has been recommended to Mr. Sherman, the meteorologist of the preliminary *Florence* expedition. The

an indication that the old mode of throwing bottles into the sea may be replaced by a new method equally simple and having at least a thousand more chances of success.

CAPT. HOWGATE'S scheme for Polar colonisation has been brought before the Council of the Paris Geographical Society, and it is expected that a resolution favourable to the contemplated expedition will be adopted in time to be sent to America before Congress has come to a final decision on that important object.

AN interesting discussion arose at the last meeting of the Anthropological Institute, on the contents of the small oval pits which have been discovered in the neighbourhood of some of the shafts at Cissbury. The president, Mr. John Evans, pointed out marks on the bone of a small ruminant, probably a roebuck, which indicated that it had been used in the process of weaving. A carding-comb, a terra-cotta bead, large enough to serve as a spindle-whorl, and a loom-weight of chalk were found in the same pit. Lord Rosehill mentioned that chalk weights were also met with in Mr. Tindale's pit at Cissbury, and some were now in his museum. Mr. Park Harrison was of opinion that the little pits were graves, but they appeared to have been disturbed at a remoter period and used for more than one interment. The potsherds found in them were of various dates, some being of a type more common on the Continent than in this country.

WE notice the appearance of the first two of the three divisions of the *Jahresbericht für Chemie* for 1876, which completes the report of physical, inorganic, organic, vegetable, and physiological chemistry, leaving the analytical, technical, mineralogical, and geological portions for the closing number. Prof. Fittica, of Marburg, is still editor-in-chief, and he is assisted by C. Böttinger, C. Hell, H. Klinger, A. Laubenheimer, E. Ludwig, A. Naumann, F. Nies, H. Salkowski, Z. H. Skraup, K. Zöppritz, G. Schultz, and W. Weyl, the latter two replacing K. Birnbaum and A. Michaelis in the editorial *corps* of the preceding year. The publication of the *Jahresbericht* has been much more prompt since the appearance of Prof. Staedel's *Jahresbericht für die reine Chemie* in 1873, which although confined exclusively to pure chemistry, renders a tolerably complete report for each year in the following September.

THE two last numbers of the *Isvestia* of the Russian Geographical Society contain a very interesting account, by Dr. Wojeikoff, of his travels in Japan, made during the summer of last year. Besides a vivid description of the country visited, and of its inhabitants, the reader will find in these papers many interesting data as to the physical characteristics of the land, with many determinations of heights, the climate, the products, &c. Two separate papers are devoted, one to the exterior trade of Japan, and the other to the population and its dependence upon agriculture, as compared with other countries.

THE Moscow Society of Friends of Natural Science has undertaken various anthropological researches for the exhibition which will take place at Moscow in 1879. One of them was made in the Ryazan government by M. Néfédoff, who has already discovered and excavated ten unknown and very interesting *koorganes* (mounds) in Kasimov district. He has found there eleven human skeletons with many ornaments, some of them in bronze, representing snakes, heads of various animals, &c.; and a comparison of the Ryazan skulls and ornaments with those excavated in the Moscow and Meriaks *koorganes*, proves that they belong to quite a different people. Altogether the discovery promises to be of great importance. Another gentleman sent by the same society, M. Bensengr is busily engaged in making anthropological measurements and ethnographical descriptions of the Ryazan Tartars.

AT the meeting of the St. Petersburg Society of Naturalists on December 9, M. Polyakoff—returned from a journey to Western Siberia, the Altai, and Alatan Mountains—read a report on the interesting question as to the state of Central Asia during the glacial period. After having described the boulder-clays, boulders, and morainic deposits he met with during his journey, as well as the present characters of the flora and fauna of the country, he concluded in favour of a complete glaciation of Central Asia during the last ice-period.

WE notice a valuable Russian work, just published by M. Mushketoff, "Materials for a Knowledge of the Geology and of the Mines of the Zlatoust Mine District in Southern Ural." It is the result of careful study, contains many new and valuable data, and is accompanied by an elaborate geological map.

AT the last meeting of the Russian Geographical Society on December 8, Prof. Ujfalvy, of the Paris High School of Eastern Languages, who was sent by the French Government on an anthropological mission to Central Asia, made a very interesting communication on his work in the Russian provinces of Orenburg, Fergana, and Turkistan. After a careful study of the Bashkirs, he arrived at the conclusion that this people are the original stock of the Madjars; that the Mescheryacks are intermediate between Bashkirs and Ostyacks, and that the Tepteri are true Tartars. The conclusions arrived at as to the various peoples of Turkistan are more complicated and could not be briefly stated; but the learned professor has collected many important data, and has obtained valuable photographs, collections of old coins from Turkistan, of stone implements from Siberia, &c.—At the same meeting M. Minaieff referred to the work he has compiled, by order of the society, on the tracts of Central Asia occupying the upper parts of the Amu-daria. The work is divided into three parts: geographical, ethnographical, and linguistic, the former being the richest, and sums up all we know at present about those lands.

COL. GORDON has lately entered into a contract with Messrs. Yarrow and Co., of Poplar, for four steel steamers of small draught. He intends exploring the Albert Nyanza and the rivers flowing into it. The steamers are to be carried as far as possible by water, and are to be composed of several portable pieces of about 200 lbs. each, to be put together on arrival at their destination. Col. Gordon and his party are reported to be good health.

SINCE the beginning of last year a new scientific journal has appeared at Christiania (Cammermeyer) under the title *Archiv for Mathematik og Naturvidenskab.* It is edited by Herrer Sophus Lie, Jakob Worm Müller, and G. O. Sars. The journal is published in four yearly parts which form a volume of about 500 pages. We have received the first seven parts, and may congratulate the editors and publishers on the decided step of progress which the appearance of this journal evidently marks in the history of Norwegian science. Amongst a number of mathematical papers by Herr Sophus Lie, and others of minor interest, there are some interesting geological treatises by Herr Karl Pettersen, viz., on the orography of Norway, on the geology of the Salten fjord, on the giant's cave near the Lxvangen fjord in the neighbourhood of Saudvort, and on the fjords of Northern Norway. Herr S. A. Sexe has contributed two papers on some old coast-lines and on the direction of the winds in the so-called "stille Belt." Herr Amund Helland is the author of a treatise on the ice-filled fjords of Northern Greenland, and of an elaborate account of the varying quantities of chlorine present in the sea-water of the German Ocean, the Atlantic, and Davis' Straits. Herr G. O. Sars contributes an interesting note on the scientific expeditions in the Atlantic during 1876, and some detailed researches on the invertebrate fauna of the Mediterranean (with plates.) Herr J. Worm Müller gives some notes on Malassez's method of estimating the number of red corpuscles in blood as well as on the relation between the number of red corpuscles and the colouring power of blood. Of the remaining papers we note—a metallurgical paper by E. Münster: on the influence of the eccentricity of the orbits of heavenly bodies upon the quantity of heat they receive from the sun, by H. Geelmuyden; and two zoological notes, one by J. Koren and D. C. Danielssen, the other by Herman Friele.

THE additions to the Zoological Society's Gardens during the past week include a Greater Sulphur-Crested Cockatoo (*Cacatua galerita*) from Australia, presented by Miss Rosetta Cohen; a Grey-breasted Parrakeet (*Bolborhynchus monachus*) from Monte Video, presented by Mr. Alex. F. Baillie; a Mocassin Snake (*Tropidonotus fasciatus*), born in the Gardens.

CERTAIN MOVEMENTS OF RADIOMETERS[1]

NEARLY two years ago Mr. Crookes was so good as to present me with two of his beautiful radiometers of different constructions, the discs of one being made of pith, and those of the other of roasted mica, in each case blackened with lampblack on one face. With these I was enabled to make some experiments, having relation to their apparently anomalous movements under certain circumstances, which were very interesting to myself, although the facts are only such as have already presented themselves to Mr. Crookes, either in the actual form in which I witnessed them, or in one closely analogous, and have mostly been described by him. Although it will be necessary for me to describe the actual experiments, which have all been repeated over and over again so as to make sure of the results, I do not bring forward the facts as new. My object is rather to endeavour to co-ordinate them, and point to the conclusions to which they appear to lead.

I do not pretend that these conclusions are established; I am well aware that they need to be further confronted with observation; but as I have not leisure to engage in a series of experiments which would demand the expenditure of a good deal of time, and have lately been urged by a friend to publish my views, I venture to lay them before the Royal Society, in hopes that they may be of some use, even if only in the way of stimulating inquiry.

In describing my experiments I will designate that direction of rotation in which the white face precedes as positive, and the reverse as negative. It will be remembered that, under ordinary circumstances, radiation towards either radiometer produces positive rotation.

1. If a glass tumbler be heated to the temperature of boiling water, and inverted over the mica radiometer, there is little or no *immediate* motion of the fly, but quickly a *negative* rotation sets in, feeble at first, but rapidly becoming lively, and presently dying away.

2. If after the fly has come to rest the hot tumbler be removed, a *positive* rotation soon sets in, which becomes pretty lively and then gradually dies away as the apparatus cools.

3. If the tumbler be heated to a somewhat higher temperature, on first inverting it over the radiometer there is a *slight positive* rotation, commencing with the promptitude usual in the case of a feeble luminous radiation, but quickly succeeded by the negative rotation already described. If the tumbler be heated still more highly, the initial positive rotation is stronger, and lasts longer, and the subsequent negative rotation is tardy and feeble.

4. If the pith radiometer be treated as in § 1, the result is the same, with the remarkable difference that the rotation is positive instead of negative; it is also less lively.

---

[1] Paper read at the Royal Society, December 20, by Prof. G. G. Stokes, Sec. R.S.

5. But if the tumbler be removed when the fly has come to rest, it remains at rest, or nearly so.

6. If the tumbler be more strongly heated, positive rotation begins as promptly as with light. In this case the tumbler must not be left long over the radiometer, for fear the vacuum should be spoiled by the evolution of gas from the pith.

7. If the tumbler be heated by holding it over the spout of a kettle from which steam is issuing, and held there till the condensation of water has approximately ceased, and be then inverted over the pith radiometer, the bulb is immediately bedewed, and a *negative* rotation is almost immediately set up, though sometimes, just at the very first moment, there is a trace of positive rotation. The negative rotation is lively, but not lasting; and after fifteen seconds or so, is exchanged for a positive rotation, which is not lively, but lasts longer.

8. If the tumbler be lifted when the negative rotation has ceased, and the dewed surface be strongly blown upon, a lively but brief positive rotation is set up.

9. To produce positive rotation by blowing it is not *essential* that the bulb be wet. If it be merely warm, and the circumstances are such that the fly is at rest for the moment, or nearly so, blowing produces positive rotation, though much less strongly than when the bulb is wet.

10. If the tumbler be heated as in § 7, and inverted over the mica radiometer, the rotation is positive, as when the tumbler is dry.

11. If the tumbler or a cup be smoked inside (to facilitate radiation), heated to a little beyond the temperature of boiling water, and inverted over the pith radiometer, a positive rotation is produced; and if, when this has ceased, which takes place in a couple of minutes or so, the heated vessel be removed, a negative, though not lively, rotation is produced as the apparatus cools.

12. These results do not seem difficult to co-ordinate so far as to reduce them to their proximate cause.

As regards the small quantity, if any, of heat radiated directly across the glass of the bulb, the action of which was experimentally distinguishable by its promptitude, both radiometers behaved in the ordinary way.

13. As regards the mica radiometer, when the bulb gets heated and radiates towards the fly the fly is impelled in the negative direction *as if* the white pearly mica were black and the lampblack were white. And there is nothing opposed to what we know in supposing that such is *really* their relative order of darkness as regards the heat of low refrangibility absorbed and radiated by the glass; for the researches of Melloni and others have shown that lampblack is, if not absolutely white, at any rate very far from black as regards heat of low refrangibility. On the other hand, glass and mica are both silicates, not so very dissimilar in chemical composition, and it would not therefore be very wonderful, but rather the reverse, if there were a general similarity in their mode of absorption of radiant heat, so that the heat most freely radiated by glass and accordingly abounding in the radiation from *thin* glass such as that of the bulb, were greedily absorbed by mica. The explanation of the reversal of the action when heat and cold were interchanged is too well known to require mention.

14. With the pith radiometer, when the bulb as a whole is heated, and radiates towards the fly, the impulse is positive, though less strong than in the case of the mica (§ 4); and when the bulb as a whole is cooler than the fly the impulse is negative (§ 11).

But to explain all the phenomena we must dissect the total radiation from or towards the bulb. When I first noticed the negative rotation produced by a heated wet tumbler, I was disposed to attribute it to radiation from the water, which possibly the glass of the bulb might be thin enough to let pass; but when I found that hot water in a glass vessel outside, even though the glass of it were thin, produced no sensible effect, and that blowing on the heated bulb when it was dry produced a similar effect to blowing on it when dewed, though of much less amount, I perceived that the moisture acted, not by direct radiation from it, and in consequence of a difference of quality between the radiations from glass and water, but by causing a rapid *superficial* heating of the bulb; and, similarly, the blowing on the dewed surface acted by causing a rapid superficial cooling. When the dry tumbler radiates to the bulb, the radiation is absorbed at various depths; the absorption is most copious, it is true, at the outer strata, but still the change of temperature is not by any means so much confined to the immediate surface as when we have to deal with the latent heat of vapour condensed on it, or obtained from it by rapid evaporation.

Hence, thin as is the glass of the bulb (about 0·02 in. thick), we must still, in imagination, divide it into an outer and inner stratum, and examine the effects of these separately. The heat radiated by either stratum depends only on its temperature, but the radiation from the outer, on its way to the fly, is sifted by passing through the inner, and the portion for which glass is most excessively opaque is in great part stopped. It appears from the observed results that the residue acts decidedly negatively, while when the bulb is pretty uniformly heated there is positive action. We may infer that if it were possible to heat the inner stratum alone it would manifest a very decided positive action.

15. In the struggle between the opposing actions of the outer and inner strata we see the explanation of the strange behaviour of the pith radiometer. In the experiment of § 7 the outer stratum at first shows its negative action, but quickly the inner also gets heated, partly by conduction from the outer, partly by direct radiation from the tumbler, and then the inner prevails. In the experiment of § 5 the whole bulb cools, partly by radiation, partly by convection, while the fly remains warmer; and the slightly greater coolness of the outer than of the inner stratum makes up for the superiority of the inner when the two are equally cool, so that the antagonistic actions nearly balance, and slight causes, such as greater or less agitation of the air, suffice to make the balance incline one way or other. That the inner stratum *would* prevail if the two were about equally cooled may be inferred from the behaviour of the radiometer when the bulb is pretty uniformly heated (§§ 4, 11), or shown more directly by cooling the bulb with snow, when a negative rotation may be obtained.

16. The complete definition of a radiation would involve the expression of the intensity of each component of it as a function of some quantity serving to define the quality of the component, such as its refractive index in a standard medium, or its wave-length, or the squared reciprocal of the wave-length.[1] The experimental determination of the character, as thus defined, of a radiation consisting of invisible heat-rays is beset with difficulties, at least in the case of heat of extremely low refrangibility; and in general we can do little more than speak in a rough way of the radiation as being of such or such a kind. It is obvious that the behaviour of radiometers by itself alone affords no indication of the refrangibilities of the kinds of heat with which we have to deal; nevertheless, by combining what we know of the behaviour of bodies in respect to radiations in general (especially luminous radiations, which are the most easily studied) with what we observe as to the motions of radiometers, we may arrive at some probable conclusions.

17. We may evidently *conceive* a series of ethereal vibrations of any periodic time, however great, to be incident on a homogeneous medium such as glass, and inquire in what manner the rate of absorption would change with the period; though whether we can actually *produce* ethereal vibrations of a very long period is another question, seeing that we can only act on the ether by the intervention of matter, and are limited to such periods of vibration as matter can assume when vibrating molecularly, in a manner communicable to the ether, and not as a continuous mass, in the manner of the vibrations which produce sound. We may inquire whether, on continually increasing the period of vibration, the glass (or other medium) would ultimately become and remain very opaque, or whether, after passing through a range of opacity, it would become transparent again, on still further increasing the period of the incident vibrations.

18. This is a question the experimental answer to which, as it seems to me, could only be given, in so far as it could be given at all, as a result of a long series of experiments, of a kind that Melloni has barely touched on. A variety of considerations, which I could not explain in short compass, lead me to regard the second alternative as the more probable, namely, that, on increasing the periodic time, homogeneous substances in general (perhaps even metals, though this is doubtful) become at last transparent, or at least comparatively so. The limit of opacity, in all probability, varies from one substance to another; and the lower it is, the lower would be the lowest refrangibility of the radiation which the same substance is capable of emitting.

19. In what immediately follows I shall suppose accordingly that glass is strongly absorbing through a certain range of low

---

[1] A map of the spectrum, constructed with the squared reciprocals of the wave-lengths for abscissæ, would be referred to a natural standard, no less than that of Angström, which is constructed according to wave-lengths; while it would have the great advantage of admitting of ready comparison with refraction spectra, the kind almost always used.

refrangibility, on *both* sides of which it gradually becomes transparent again.[1] Imagine a spectrum containing radiations of all refrangibilities with which we have to deal; let portions of this spectrum on the two sides of the region of powerful absorption for glass be called *wings* of that region, and let left to right be the order of increasing refrangibility. Then the spectrum of the radiation from a thin plate of glass, if it could be observed, would be seen to occupy the region of chief absorbing (and therefore emitting) power and its wings. The spectrum of the radiation from the outer stratum of the bulb of the pith radiometer, after transmission through the inner, would consist of two wings, with a blank, or nearly blank, space between; it would resemble, in fact, a widened bright spectral line, with a dark band of reversal in its middle, save that, instead of being confined to extremely narrow limits of refrangibility, the central space and its wings would be of wide extent. It follows from the experiments that, in the complete radiation from glass, the portions of the spectrum called the wings together act negatively, the portion between positively. It does not, of course, follow that each wing acts negatively, but only that the balance of the two is negative. When the tumbler is heated a little over 212° there is a slight positive action from radiation which passes directly through the bulb. The circumstances lead us to regard this as an extension of the right wing; for it comes from a depth, measured from the inner surface of the bulb in glass, *i.e.*, not counting the intervening air, somewhat greater than the thickness of the wall of the bulb; and we know that the more a solid body is heated, the higher, as a rule, does the refrangibility of the radiation which it emits extend, and the greater the proportion of rays of high to those of low refrangibility. It is simplest, therefore, to suppose that the action of the right wing, like that of the space between the wings, is positive, and that the observed negative action in the experiment of § 7 is due to the excess of negative action of the left wing over positive action of the right. In the mica radiometer the experiments indicate no such difference of action in the different layers of the bulb as in the case of the pith radiometer. Hence taking, in accordance with what now appears to be made out to be the theory of the motion of the radiometer, the direction in which the fly is impelled as an indication which is the warmer of the two faces of the discs, and that again as an indication which is the darker with respect to the radiation to which it is exposed, we arrive at the following results as regards the order of darkness of the substances for the three regions into which the spectrum of the incident radiation has been supposed to be divided, the name of the lighter substance being in each case placed above that of the darker:—

	Left wing.	Region of intense absorption by glass.	Right wing.
From pith radiometer ...	Lampblack. Pith.	Pith. Lampblack.	Pith. Lampblack.
From mica radiometer ...	Lampblack. Mica.	Lampblack. Mica.	Mica Lampblack.

Hence, on descending in refrangibility, the order of darkness of the two substances of either pair is at first the same as for the visible spectrum, and at last the opposite; and the reversal of the order takes place sooner with mica and lampblack than with pith and lampblack. The order falls in very well with that of the chemical complexity of the three substances.

20. The whole subject of the behaviour of bodies with respect to radiant heat of the lowest degrees of refrangibility seems to me to need a thorough experimental investigation. The investigation, however, is one involving considerable difficulty. We can do little towards classifying the rays with which we are working unless we can form a pure spectrum. A refraction spectrum is the most convenient; but the only substance known which would be approximately suitable for forming the prism, lens, &c., required for such a spectrum, and for confining liquids, is rock-salt, of which it is extremely difficult to procure perfectly limpid specimens of any size; and even rock-salt itself, as Prof. Balfour Stewart has shown, is defective in transparency for certain kinds of radiant heat. Then, again, the only suitable measuring-instrument for such researches, the thermopile, demands a thorough examination with reference to the coating to be employed for absorbing the incident radiation. Hitherto lampblack has been used almost exclusively for the purpose; and it is commonly assumed, in accordance with certain of Melloni's results, that lamplack absorbs equally heat-rays of all kinds. But the experiments by which Melloni established the partial diathermancy of lampblack prove that rays exist for the absorption of which that substance is unsuitable.

On calling on Mr. Crookes after the above was written, I was surprised to find that all his mica radiometers behaved towards a heated glass shade in the opposite way to that he had given me, going round positively instead of negatively. Mr. Crookes showed me and gave me a specimen of the kind of mica he employs as eminently convenient for manipulation. It is found naturally in a condition resembling artificially roasted mica. It is not, however, quite so opaque for transmitted light, nor of quite such a pearly whiteness for reflected light as that which has been artificially roasted at a high temperature. The mica radiometer that Mr. Crookes first gave me, which I will call M_1, was, Mr. Gimingham told me, the only one they had made with roasted mica.

Mr. Crookes was so kind as to give me, for comparative experiment, a mica radiometer, which I will call M_2, made from the natural foliated mica. It revolves a good deal more quickly than M_1 under the influence of light; it also gets more quickly under way, indicating that the mica is thinner. When covered with a hot glass it revolves positively, as already remarked; there is, however, but little negative rotation when the glass is removed.

The difference in the thickness and condition of the mica sufficiently explains the difference of behaviour of M_1 and M_2. Any radiant heat incident on the white face that reaches the middle of the mica, whether it afterwards is absorbed by the mica or reaches and is absorbed by the lampblack, tends to heat the second or blackened face more than the first, and therefore conspires with the heat incident on the lampblack, and absorbed by it, to produce positive rotation; and the smaller thickness and less fine foliation of the natural mica are favourable to the transmission of radiant heat to such a depth.

P.S.—It might be supposed at first sight that the change of rotation from negative to positive (in § 7) was due, not to a change in the conditions of absorption, but to the circumstance that the inner surface of the bulb had become warm by conduction, so as to be warmer than the surfaces of the fly instead of colder. For we now know that the "repulsion resulting from radiation," as in some way or other it undoubtedly does result, is an indirect effect, in which radiation acts only through the alterations it occasions in the superficial temperatures of the solids in contact with the rarefied gas; and it might be supposed that when the inner surface of the bulb passed from colder than the fly to warmer, the direction of rotation would, on that account alone, be reversed. This, however, is not so. If bulb and fly are at a common temperature, and the instrument is protected from radiation, the fly remains at rest whether the common temperature be high or low. If a small portion of the total surface in contact with the rarefied gas be warmed by any means, repulsion takes place, through the intervention of the rarefied gas, between the warmed surface and the opposed surfaces, if not too distant; if it be cooled, the result is attraction. It does not matter whether the surface at the exceptional temperature belong to the fly or the bulb. The former takes place in the ordinary case of a radiometer exposed to radiation, the latter in that of a radiometer at a uniform temperature and protected from radiation when a small portion of the bulb is warmed or cooled, in which case the part at the exceptional temperature repels or attracts the disc irrespectively of its colour or the nature of its coating.[1] Suppose now that the fly is being warmed by radiation from without, the bulb being cool, at least at its inner surface. Let A, B be the two kinds of faces of the discs, and suppose A to be the better absorber of the total radiation. Then A will be the warmer, and therefore will be more strongly repelled than B. Suppose now that the bulb is heated till its inner surface becomes warmer than the fly. Then the fly will still be receiving heat by radiation, to some extent also by communication from the gas; but this will be the same for both faces. Hence if A be still the better absorber of the two (A, B), A will be the warmer, and being less below the temperature of the interior surface of the fly will be less attracted, or, which is the same, more repelled. Hence, whether the inner surface of the bulb be cooler or hotter than the fly, a reversal in the direction of rotation while the fly is being heated, indicates a reversal in the order of absorbing power of the two faces, and that, again, shows that the order is different for different components of the total radiation, and that the ratio of the intensity of those components has been changed.

---

[1] It may be noticed that this supposition, which, as appearing the more probable, is adopted for clearness of conception, is not essentially involved in the explanation that follows, which would hardly be changed if the "left wing" were not terminated on the left.

[1] Theoretically there would be a minute difference of temperature, produced, other circumstances being alike, by the difference in the absorbing or emitting power of the two faces of a disc, as regards the radiation which is the difference between the radiations from or towards the affected portion of the bulb and the same portion at the normal temperature. But this, and the repulsion or attraction corresponding to it, would be only a small quantity of the second order, the main effect being deemed one of the first order.

It is perhaps hardly necessary to observe that the radiometers mentioned in this paper are of the usual form—that is to say, that their arms are symmetrical, so far as *figure* is concerned, with respect to a vertical plane passing through the point of support. Accordingly the rotation which is attained, for instance, with a radiometer with concave disks of aluminium, alike as to material on both faces (of which kind, again, I owe a beautiful specimen to Mr. Crookes's kindness), has not been referred to. This rotation, depending on the more favourable presentation to the bulb of the outer (and therefore nearer and more efficient) portions of the fly on the convex than on the concave side, has nothing to do with the one isolated subject to which the present paper relates, namely, the elucidation of the peculiar behaviour in certain cases of certain kinds of radiometers, by a consideration of the heterogeneous character of the total heat-radiation.

(*To be continued.*)

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

LEEDS.—By the liberality of the Worshipful the Drapers' Company, the Council of the Yorkshire College are prepared to appoint an instructor in coal mining at the stipend of 100*l.* per annum and half the students' fees. A portion only of the instructor's time will be required. The fuller conditions and duties of the office may be learned from the secretary. Applications and testimonials must be received on or before January 18.

LEXINGTON, U.S.—In connection with the Centennial, efforts have been made in the United States to raise an endowment fund for Washington and Lee University, at Lexington, Va. The institution dates from colonial times, and was endowed, while it was still only an academy, by Washington and other soldiers of the Revolution. Among other recent benefactors of the University is Mr. L. J. McCormick, of Chicago, who has offered to give his magnificent telescope, made by Alvan Clark, of Cambridge, U.S., at a cost of 50,000 dols., provided the institution would raise the necessary funds to equip and maintain it. The trustees have not yet been able to do anything towards the acceptance of this proposal. It would be a great misfortune if the conditions could not be complied with, and we hope that the suggestion that the ladies in various parts of the States should take the matter up will be complied with; there is no doubt if they make up their minds to success they will succeed.

BERLIN.—The great Prussian university is closely competing now with the Leipsic University in point of attendance. In the calendar which has just appeared we notice that the number of matriculated students during the present winter amounts to 2,839, an increase of 600 on the summer semester. They are divided among the faculties as follows: theological 168, legal 1,163, medical 345, philosophical 1,163. There are 210 foreigners in the list, including 42 from America. Besides these matriculated students, there are 2,200 other persons in attendance on the lectures, belonging to the various technical and art schools of the city. The corps of instructors numbers 210, nearly half of whom are in the philosophical faculty.

BONN.—The winter attendance at the University is 859, an increase of sixty-two on the preceding semester. The philosophical faculty includes 375, the legal 219, the medical 126, the Catholic theological, 89, and the Evangelical, 50.

SOCIETIES AND ACADEMIES

LONDON

Linnean Society, December 6.—Prof. Allman, president, in the chair.—Messrs. J. N. Fitch, J. S. Gamble, F. S. Piggott, A. B. Stewart, and Prof. Macoun were elected Fellows.—Mr. Thiselton Dyer exhibited portions of the "Nam-mu" tree, which grows in Yunnan, 25°–26° N. lat. The Chinese nobility greatly prize its wood for building purposes and for making coffins, and enormous columns in tombs of the Ming dynasty, 300 years old, are still extant. Supposed to be teak, it probably rather belongs to the Lauraceæ, the leaves closely resembling those of *Phœbe pallida*. Mr. Dyer also exhibited a seed of *Entada scandens*, and another of an anonaceous plant (*Cyathocalyx Maingayi ?*) found in the cæcum of *Rhinoceros sumatrensis* from Chittagong, and dissected at the Zoological Gardens, Regent's Park; and he likewise showed fruits of *Oncocarpus vitiensis* from the crop of a fruit-pigeon (*Carpophaga latrans*).—Attention was afterwards called by Mr. Dyer to the fruit-head of an Indian *Pandanus* made into a brush, the fibrous tissue of the drupes forming the bristles, and this instrument was said to be used to scrape cloth, like our teazle (*Dipsacus*).—Flowers and foliage of Cinchona (*C. calisaya*, vars., *Josephiana* and *Anglica*) grown in the garden of Mr. J. Elliot, at Tottenham, were exhibited by that gentleman, whose researches among the quinine-bearing trees are already well known and appreciated.—Mr. Moggridge read a note on the occurrence at Wallis Down, a heath near Bournemouth, of *Dabeocia polifolia*.—A paper on certain organs of the Cidaridæ was communicated by Mr. Chas. Stewart, who illustrated, amongst others, the subjoined points of his recent investigations. Among the sea-urchins the families Diadematidæ, Echinometridæ, and Echinidæ, have long been known to possess external branchiæ; but the existence of such in the Cidaridæ has been denied by Müller, though insisted on by Alex. Agassiz. Mr. Stewart finds in *Dorocidaris papillata* five organs corresponding to branchiæ, but situated internally. The water bathing these interior gills finds ingress and egress by a crevice near the "compasses," the peculiar mechanism of the teeth and jaws producing the temporary opening in question. As respects the pedicellariæ of Cidaridæ, where the jaw ends in a terminal hollow fang, there is an additional orifice to that at the tip, besides two glands in the vicinity; he suggests this to be a poison apparatus, comparable to the falces of the spider, and poison sac and tooth of venomous serpents.—The Secretary read a paper by Dr. I. Bayley Balfour, "Observations on the genus *Pandanus*." Few families of plants present more difficulty in their elucidation than the Pandanaceæ; this by variability of species, difficulty of procuring the male flower, with little character in the leaves, while the fruit loses its distinctive features in drying. The Screw-pines had attracted the notice of the early voyagers, but their descriptions are confused. To Rumphius we owe the name Pandanus, though his account and figures are poor compared with Reede's of a century before. Linnæus, though indicating a plant under the name *Bromelia sylvestris*, omitted the genus *Pandanus*, a want supplied by his son. Afterwards, as species increased, many new genera were unnecessarily introduced, which Dr. Balfour is now inclined to reject; even Brongniart's New Caledonia genera do not claim acceptance. *Pandanus* runs over a great breadth of longitude, viz., from east tropical Africa through the Mascarene Islands, India, Indian Archipelago, and Australia, to the Sandwich Islands. The East Archipelago and the Mascarenes are centres whose species do not commingle. There succeeds in this paper other facts and an extensive list of names and references to all the Pandani known.—The substance was given of a report on a small collection of insects obtained by Dr. J. C. Ploem, in Java, with description of a new species of *Hoplia*, by Chas. O. Waterhouse, of the British Museum.—The Secretary read a communication by Dr. J. Stirton, viz., "Notes on the Rev. Mr. Crombie's paper on the Lichens of the *Challenger* Expedition," and another note by Dr. R. C. A. Prior, relative to the migration of wild geese, purported to have passed from North America to the African coast.

Physical Society, December 15.—Prof. G. C. Foster, president, in the chair.—The following candidates were elected Members of the Society:—W. E. Ayrton, J. M. Cameron, J. W. Clark, J. E. Judson, B.A., H. N. Moseley, M.A., F.R.S., Lord Rayleigh, M.A., F.R.S., W. N. Stocker, M.A., and H. T. Wood.—Mr. C. W. Cooke read for the author, Prof. S. P. Thompson, a paper on permanent Plateau films, and exhibited the process of their formation. After a brief enumeration of the various attempts made by Plateau himself, Schwartz, Mach, Rottier, and others, most of which are described in the work of Plateau, the author described his own experiment on the subject. As the result of these he concludes that the best films are obtained by using a mixture of 46 per cent. of pure amber-coloured resin, and 54 of Canada balsam, which should be heated to from 93° to 95° C. The frames for forming the films are made of brass wire 0·3 mm. in diameter, and when thicker wire is employed they are found to be irregular in consequence of the retention of heat by the metal. The films are obtained by simply introducing these frames into the heated mixture, and they harden almost immediately on exposure to the air; but better results are obtained by slow drying in an air bath heated up to 80° C., and allowed to cool. In proof of the toughness of the films it was mentioned that a flat circular film 4 cm. in diameter, had supported a 50-gramme brass weight at its centre.—Mr. Sedley Taylor then exhibited some experiments in illustration of a paper on the colours exhibited by vibrating liquid films which he has recently communicated to the Royal Society.—Dr. Guthrie exhibited a simple lecture illustration of the action of the telephone. Two similar coils of wire are placed one on the end of a bar magnet, and the other on a soft iron core. A tin disc about three inches in diameter is suspended by two threads almost in contact with one end of this latter, and when a similar disc is brought, at regular intervals, against the end of the magnet which is provided with the coil, a distinct movement of the first-named disc is observed which can be easily increased by properly timing the movement of the inducing disc.

Anthropological Institute, November 27.—Mr. John Evans, D.C.L., F.R.S., president, in the chair.—The election of five new members was announced.—Major-Gen. A. Lane Fox, F.R.S., exhibited various objects from Istria and Scinde.—The Director read some notes on Socotra, by Capt. Hunter, R.N., in which some of Lieut. Wellstead's statements about that island were criticised.—A paper on the Záparos, by Mr. A. Simpson, was then read, in which many interesting observations of these tribes of "Equador" were recorded. Their wonderful tracking powers, abstention from heavy meats, such as tapir and peccari, curious mode of training hunting-dogs, were described. Their enjoyment in the destruction of life, human or animal, with the exception of the alligator, which they will not touch themselves, was very marked. The Napos do not resemble them in this respect. The Záparos are very disunited, and wander about in separate hordes, the worst of which are the Supinus. Courtship is sometimes carried on by a silent invitation by the suitor to his elect to cook his food. If rejected, he tries elsewhere. The Záparos are described as of a happy and cheerful disposition, very superstitious, believing in an evil spirit, and very poor and almost nude.—A paper on the Malayo Polynesians, by Rev. S. J. Whitmee, was then read, in which the author noted the high social position of women in the Samoan group, as compared with their place among the *black* Polynesians. The existence of hereditary ranks and titles among the *brown* Polynesians seems to the author to indicate a former higher condition. The author referred to the difficulties experienced by missionaries in obtaining the true versions of the native poems and myths, and noted the custom of preserving the myths in poetry as well as prose, the two versions acting one as a check on the other, and so preserving the correctness one of the other. In the discussion, Major-Gen. A. Lane Fox, Mr. Blackmore, Mr. Hyde Clarke, and others, took part.

Entomological Society, December 5.—J. W. Dunning, vice-president, in the chair.—Mr. W. L. Distant exhibited specimens of the rare species of Hemiptera-Heteroptera, *Tetroxia beauvoisii*, and *Oncocephalus subspinosus*, from the West Coast of Africa.—Mr. F. Smith exhibited a fine series of *Macropis labiata*, male and female, captured near Norwich by Mr. I. B. Bridgman.—Mr. Smith also exhibited a specimen of *Kophites quinquespinosus*, a genus and species new to the British Hymenoptera, captured near Hastings by the Rev. E. H. Bloomfield.—Mr. Meldola exhibited three fine photographic enlargements of micro-photographs (two being of parts of insects) taken by Mr. Edward Viles, of Pendryl Hall, Wolverhampton. The photographs, which had been exhibited at the recent exhibition of the Photographic Society were 30 x 24 in., while the original negatives were 3 in. square.—Mr. Meldola likewise performed an acoustical experiment illustrating the action of the stridulating apparatus in the *Phasma* (*Pterinoxylus*), an account of which had been given to the society by Mr. Wood Mason at the last meeting.—Mr. Wood Mason made further remarks on the structure of the stridulating organ in scorpions.—Mr. F. Smith mentioned a case of stridulation occurring in a British species of *Curculionidæ* (*Acalles*).—Mr. Dunning called attention to a striking case of mimicry recorded by Mr. Neville Goodman in the *Proceedings* of the Cambridge Philosophical Society for February, 1877, the mimic being a species of *Laphria*, and the model, the well-known Egyptian hornet, *Vespa orientalis*.—Mr. F. Smith read a paper containing descriptions of new species of hymenopterous insects from New Zealand, collected by Prof. Hutton at Otago.—Mr. A. G. Butler communicated a paper on the Lepidoptera of the Amazons, collected by Dr. James W. H. Trail during the years 1873 to 1875.—Dr. Sharp communicated the following papers:—Descriptions of eight new species and a new genus of Cossonides, from New Zealand, and descriptions of some new species and a new genus of Rhyncophorous Coleoptera, from the Hawaiian Islands.

MANCHESTER

Literary and Philosophical Society, October 16.—Mr. E. W. Binney, F.R.S., president, in the chair.—The President exhibited to the meeting some coal-measure plants and other organic remains from Spain. From the character of the fossil organic remains and the nature of the strata he was led to believe that the coal-field of Puertollano was of the same geological age as our true English coal-measures.—Mr. M. P. Pattison Muir, F.R.S.E., exhibited and gave a description of a modified form of Hofmann's apparatus for determining vapour densities.—Note on an edible clay from New Zealand, by M. M. Pattison Muir, F.R.S.E. The author lately received from Mr. R. E. Day, a small specimen of a clay which is greedily eaten by the sheep in a certain district in New Zealand. The clay was brought by Mr. Day from Simon's Pass Station, Mackenzie Country, South Island. It there forms a range of low bare hills: the sheep (merino sheep) eat very considerable quantities of the clay without appearing to be any the worse for it. It is supposed by the shepherds that the clay must contain salt, and that it is to supply the deficiency of this article of food that the sheep resort to the earth. The analysis shows that very probably the shepherds are right:—Silica, 61·25; alumina, 17·97; ferric oxide, 5·72; calcium oxide, 1·91; magnesium oxide, 0·87; alkalies (as chlorides), 3·69; organic matter, 1·77; water, 7·31 = 100·49.—On the decomposition of calcium sulphate by alkaline chlorides; a contribution to agricultural chemistry, by M. M. Pattison Muir, F.P.S.E.—On some thionates, by H. Baker, student in the Owens College. Communicated by Prof. C. Schorlemmer, F.R.S.

VIENNA

Imperial Academy of Sciences, October 18.—On the chemical nature of peptone and its relation to albumen, by M. Herth.—On the addition of prussic acid to urea, and on the action of trichloric lactic acid on urea, by M. Cech.—Transformation of cyanamide into ammelide, by MM. Cech and Dehmel.—New discoveries on the negative heliotropism of above-ground parts of plants, by M. Wiesner.—On Fraunhofer's rings, Quetelet's stripes, and allied phenomena, by M. Exner.

October 25.—On the connection of *n* straight lines in the plane, and on properties of the triangle and two propositions of Steiner therewith connected, by M. Kantor.—On the structure and the growth of some forms of mould-fungus, by M. Hassloch.—On the development of the small pollen-plants of *Colchicum autumnale* L., by M. Tomaschek.—On the secular acceleration of the mean motion of the moon, by M. v. Littrow.

the employment of sulphurous acid, by giving the gas time to cool after compression. M. Cailletet has not yet obtained, at all events, so far as we yet know, oxygen in a liquid form, as M. Pictet has done; on being separated from its enormous pressure it has merely put on the appearance of a cloud.

M. Pictet's arrangements are more elaborate. He uses four vacuum- and force-pumps, similar to those which were recently exhibited in the Loan Collection of Scientific Apparatus for making ice, driven by an engine of 15-horse power. Two of these are employed in procuring a reduction of temperature in a tube about four feet long containing sulphurous acid. This is done in the following way: the vacuum pump withdraws the vapour from above the surface of the liquid sulphurous acid in the tube, which, like all the others subsequently to be mentioned, is slightly inclined so as to give the maximum of evaporating surface. The force-pump then compresses this vapour, and sends it into a separate reservoir, where it is again cooled and liquefied; the freshly-formed liquid is allowed to return under control to the tube first referred to, so that a complete circulation is maintained. With the pumps at full work there is a nearly perfect vacuum over the liquid and the temperature falls to – 65° or – 70° C.

M. Pictet uses this sulphurous acid as a cold-water jacket, as we shall see. It is used to cool the carbonic acid after compression, as water is used to cool the sulphurous acid after compression.

This is managed as follows:—In the tube thus filled with liquid sulphurous acid at a temperature of – 60° C. there is another central one of the same length but naturally of smaller diameter. This central tube M. Pictet fills with liquid carbonic acid at a pressure of four or six atmospheres. This is then let into another tube four metres long and four centimetres in diameter. When thus filled the liquid is next reduced to the solid form and a temperature of – 140° C., the extraction of heat being effected as before by the pump, which extracts three litres of gas per stroke and makes 100 strokes a minute.

Now it is the turn of the oxygen.

Just as the tube containing carbonic acid was placed in the tube containing sulphurous acid, so is a tube containing oxygen inserted in the long tube containing the now solidified carbonic acid. This tube is five metres long, fourteen millimetres in exterior diameter, and only four in interior diameter—the glass is very thick. The whole surface of this tube, except the ends which project beyond the ends of the carbonic acid tube, is surrounded by the frozen carbonic acid.

One end of this tube is connected with a strong shell containing chlorate of potash, the other end is furnished with a stop-cock.

When the tube was as cold as its surroundings, heat was applied to the chlorate, and a pressure of 500 atmospheres was registered; this descended to 320. The stop-cock was then opened, and a liquid shot out with such violence that none could be secured, though we shall hear of this soon.

Pieces of lighted wood held in this stream spontaneously inflamed with tremendous violence. "

In this way, then, has oxygen been liquefied at last. But this result has no sooner filled us with surprise than it has been completely eclipsed. On the last day of December, a week after the meeting of the Academy to which we have referred, M. Cailletet performed a series of experiments in the laboratory of the École Normale at Paris, in the presence of Berthelot, Boussingault, St. Claire Deville, Mascart, and other leading French chemists and physicists, using the same method as that formerly employed for oxygen and he then and there liquefied hydrogen, nitrogen, and air!

M. Cailletet first introduced pure nitrogen gas into the apparatus. Under a pressure of 200 atmospheres the tube was opened, and a number of drops of liquid nitrogen were formed. Hydrogen was next experimented with, and this, the lightest and most difficult of all gases, was reduced to the form of a mist at 280 atmospheres. The degree of cold attained by the sudden release of these compressed gases is scarcely conceivable. The physicists present at the experiment estimated it at – 300° C.

Although oxygen and nitrogen had both been liquefied, it was deemed of interest to carry out the process with air, and the apparatus was filled with the latter, carefully dried and freed from carbonic acid. The experiment yielded the same result. On opening the tube a stream of *liquid air* issued from it resembling the fine jets forced from our modern perfume bottles.

These more recent results are all the more surprising as, at an earlier stage, hydrogen, at a pressure of 300 atmospheres, has shown no signs of giving way.

These brilliant and important results, though, as we have said, they give us no new idea on the constitution of matter, open out a magnificent vista for future experiment. First, we shall doubtless be able to study solid oxygen, hydrogen, and air, and if MM. Pictet and Cailletet succeed in this there will then be the history to write of the changes of molecular state, probably accompanied by changes of colour, through which these elemental substances pass in their new transformations.

There is a distinct lesson to be learnt from the sources whence these startling *tours de force* have originated. The means at the command of both MM. Cailletet and Pictet arise from the industrial requirements of these gentlemen, one for making iron, the other for making ice.

Why then in England, the land of practical science, have we not more men like MM. Cailletet and Pictet to utilise for purposes of research the vast means at their disposal, or at all events to allow others to use them?

It is also clear that to cope with modern requirements our laboratories must no longer contain merely an antiquated air-pump, a Leyden jar, and a few bottles, as many of them do. The professor should be in charge of a work- instead of an old curiosity-shop, and the scale of his operations must be large if he is to march with the times—times which, with the liquefaction of the most refractory gases, mark an epoch in the history of science.

HUXLEY'S PHYSIOGRAPHY

Physiography: an Introduction to the Study of Nature. By T. H. Huxley, F.R.S. (London: Macmillan and Co., 1877.)

AMONG educational works which are calculated to afford real assistance to the teacher in his all-important labours, we may recognise two distinct classes. One of these includes the "text-books," which should aim at presenting only the accurate and well-proportioned outlines of a system of instruction, leaving it to the teacher himself so to fill in these outlines with explanation and illustration, as to cause the new facts and reasonings to produce the most vivid and abiding impressions upon the minds of his pupils. But inasmuch as the attainment of such a result demands much practical skill and educational tact—a skill and tact which are by no means easy of acquirement—the necessity and value of another class of works becomes manifest. This second class of educational works comprises such as aim at instructing the teacher how best to perform his difficult task; which exemplify the work of explanation, illustrate the art of illustration, and show how the dry bones of barren facts may, by clear arrangement and logical connection, be compacted into a body of real knowledge, and this body by being infused with the earnest intelligence of the teacher, may be quickened into active and fruitful life in the minds of the scholars.

It is to this latter very important class of educational works that we should be inclined to refer the book before us, and we cannot therefore regard the designation of it as a "manual for students," which is borne upon its cover—one for which we suspect that the author is not himself responsible—as either happy or judicious. That some instruction in the physical laws of that universe in which we are placed ought to form a recognised part of our system of elementary education has been again and again maintained and strongly insisted upon by scientific men, and by none more persistently or more urgently than by the author of the present work. When we reflect on the fact that to the man who has learnt to recognise, obey and apply these laws, Nature reveals herself as a helpful and bountiful mother, ever ready to aid him n his industry, his arts, and his commerce; while to him who ignores or violates these laws she is known only as a terribly relentless and avenging goddess, ever thwarting his most earnest endeavours, and scourging him with plagues, pestilences, and famines—it is hard to realise how slowly the necessity for this instruction in natural knowledge has forced itself upon the minds of those who are responsible for the scheme of elementary education adopted in this country. But society—the machinery of which is every day becoming more complicated and more susceptible to those painful consequences which follow from the infringement of the laws of nature—will doubtless in the end demand, as indeed it has a right to do, that every unit in her organisation should be fitted so to play his part, as to avoid the danger to himself and others which the neglect or violation of natural laws invariably entails.

Almost every demand that the principles of physical science should be taught in our elementary schools, has been met with the objection that our knowledge of nature and her laws has in recent years grown to such an extent, and ramified into so vast a number of channels as to make any attempt to teach it to the young quite hopeless. As well might we point to the number of volumes in the library of the British Museum, and declare that their existence demonstrates the uselessness of teaching the art of reading. No one, of course, would desire that an epitome all the sciences should be taught to children; but what is demanded is that the methods of modern scientific thought should be made familiar to every mind, that a few leading and necessary truths should be taught concerning the world in which we live and the laws which control its potent forces (seeing that upon our knowledge or ignorance of these depends much of our happiness and success or our misery and failure in the adventure of life), and that, last but not least, the minds of all young people should be conducted within the threshold of the temple of natural knowledge, so that any among them that may be endowed with the necessary capabilities may learn there to dedicate themselves to the pursuit of science.

How can this elementary instruction in science be best imparted to the young? This is the important question which Prof. Huxley applies himself to answer in the work before us; and he accomplishes his object much better by means of example than he could by any amount of discussion of the general principles of the art of teaching. On several other occasions the author has indicated the importance of making a knowledge of the more striking phenomena of nature, those with which we come into contact in our every-day life, and which exercise the greatest influence on our daily occupations and experiences, the starting-point of our introduction to the world of scientific thought; and it is to this vestibule of the temple of natural science that he applies the name of "Physiography."

The author of the present work of course recognises that first principle of good teaching which consists in fastening at first on facts and ideas which are known and familiar, and from thence leading the minds of the student by a succession of steps, no one of which shall present any serious difficulties, up to those more unfamiliar observations and those less obvious deductions from them, which if presented in the first instance might startle and repel rather than attract the scholar. We must ask the reader himself to trace in the work before us how, setting out from the most striking and easily observed facts about the River Thames, Prof. Huxley shows his admirable skill in teaching by leading his readers through a series of reasonings couched in simple and untechnical, but always accurate and elegant, language, up to the grandest truths in physics, biology, geology, and astronomy; how, throughout, happy analogies and telling illustrations make the path of the scholar, light, easy, and pleasant; and how in all this nothing of the exactness and dignity of science is sacrificed to a desire to say those fine or funny things which are too often supposed to convert a prosy book into a "popular" one.

The teacher who takes these easy lessons in elementary science and simply repeats them to his scholars can scarcely fail to communicate some sound and useful instruction to them. But every competent and judicious teacher will prize Prof. Huxley's book rather as a model than as a "crib"—and this is the light in which the author, we are persuaded, would desire that his work should be regarded by them. It is as easy, for example, to make the Mersey, the Severn, the Forth, or the Clyde the starting point of our studies of nature, as the Thames, and in Manchester, Bristol, Edinburgh, or Glasgow respectively, it is far better to do so; nor will any well-instructed teacher find the smallest difficulty in thus adapting his lessons to his auditory. To such teachers as have never studied or thought on scientific questions themselves, our advice would be to content themselves with placing Prof. Huxley's book in their school-libraries, and not to run the risk of spoiling its teachings by filtering them through their own minds.

We have spoken at such length on the value of this work to the teacher, as to leave but little space for reference to its interest to the general reader, yet this is by no means small; to those who seek an "introduction to the study of nature," which shall be at the same time both sound and readable, exact and untechnical, we most heartily commend the work before us.

We are informed in the preface that the idea of this work has long been entertained, and its plan and methods frequently revolved in the mind of the author. It is probable that not a little of its present excellence is due to this slow maturation of its plan, assisted, as we learn that its development has been, by its embodiment in two successive courses of lectures—on the shorthand notes of one of which the present book is based. In seeking for an editor to relieve him of the more trying labour of book-making, Prof. Huxley has been fortunate in securing the services of Mr. Radler, whose knowledge of a great number of branches of science is combined with much literary skill. To this cause we may attribute the small number of inaccuracies in either fact or expression which a careful perusal of the work has revealed. Such as do occur may be easily remedied in the new edition, which we have no doubt will soon be called for.

In concluding this notice we cannot refrain from congratulating its author upon the production of the work, and at the same time of assuring him that among all the labours he has undergone, and the sacrifices he has made on behalf of elementary education in this country, none is likely to produce more valuable and more enduring fruit than this much-needed model of the art of teaching the fundamental truths of natural science, the appearance of which at the present time we cannot but regard as being most opportune.

J. W. J.

OUR BOOK SHELF

Myths and Marvels of Astronomy. By Richard A. Proctor. (London: Chatto and Windus, 1878.)

THE author observes in his preface that "the chief charm of astronomy with many does not reside in the wonders revealed to us by the science, but in the lore and legends connected with its history, the strange fancies with which in old times it has been associated, the half-forgotten myths to which it has given birth," and further remarking that in our own times myths and fancies, startling inventions and paradoxes have also found place, he has framed the present volume to meet the tastes of the class of readers which he believes to be specially interested in such matters.

In a work confessedly written with this object in view, perhaps it will hardly be expected that there can be much to require notice in a scientific journal. An important point will be accuracy of detail, and in this respect, except in two or three cases, we remark little to which exception can be taken. Amongst other subjects, the author enters upon "the religion" and the mysteries of the Great Pyramid, "Suns in flames," the rings of Saturn, comets as portents, the notorious lunar-hoax of 1835-36, and the origin of the constellation-figures. He is unlucky in his notice of the first discovery of the famous star of Tycho Brahe in 1572, reproducing from Sir John Herschel's "Outlines," the story of Tycho's attention having been first directed to the object on the evening of November 11, by seeing "a group of country people gazing at a star which he was sure did not exist an hour before." This story is as much a myth as anything in the volume before us, as will be evident to the reader who consults the account of his first observation and of the observations of others given by Tycho himself, and it is strange that the statement which has misled Mr. Proctor should have been continued in the various editions of Sir John Herschel's "Astronomy" since the year 1833. The account given in the chapter "On some Astronomical Myths" of the actual position of the intra-Mercurial planet question is too incomplete to enable the reader to form a competent judgment thereupon, though it may leave him under the impression that there is something mythical about it. Mr. Proctor appears to reject "the idea of wilful deception" on the part of astronomical observers—in which case the mere expression of disbelief in the existence of an intra Mercurial body or bodies does not assist explanation of recorded observations, more particularly where motion has been remarked. There are a few numerical errors in the volume, as in the note on p. 235, where it is stated that the comet of the August meteors has "a period of at least 150 years;" so long a period would be irreconcilable with the observations, and the very complete investigation by Prof. Oppolzer assigns 121½ years as the most probable length of the revolution. But as already stated there is general accuracy of detail, and the volume will doubtless be found acceptable to the particular class of readers for whom it has been prepared.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.]

Electrical Experiment

THE inclosed letter gives an account of an experiment in which an electric current appears to be produced by the direct action of gravity, a result which, if clearly established, would be new and of considerable scientific interest.

In trying to repeat the experiment yesterday I observed a considerable deflexion of the galvanometer in the direction described by Mr. Pirani, but as this deflexion seemed to occur some seconds *after* the inversion of the tube, I examined the tube and found a small bubble of air working its way up through the solution, and as soon as it came to the top of the tube the deflexion occurred.

I have not yet had time to repeat the experiment without the bubble, but I mention this to show that care must be taken to secure that the electrolyte is homogeneous, and that it does not contain anything which will either sink to the bottom of the tube or float to the top, so as to act alternately on the two electrodes.

The fact that the deflexion continued for some time after the tube was placed horizontally seems to indicate the possibility of something which was shifted from end to end when the tube was inverted, but remained where it was when the tube was only laid on its side.

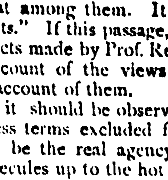
J. CLERK MAXWELL

Cavendish Laboratory, Cambridge, December 28, 1877

"University of Melbourne, Oct. 30, 1877

"MY DEAR SIR,—On page 317 of vol. i. of your 'Electricity and Magnetism' it is pointed out that a greater electromotive force is required to produce a given current between zinc electrodes in a solution of sulphate of zinc when zinc is carried upwards than when it is carried downwards.

"I am not aware that it has been noticed that by the same reasoning as that by which the induction of currents is deduced from the force exerted between a circuit and a magnet and the existence of contact electromotive force from the Peltier effect, it follows that a current should exist if two zinc electrodes connected by a wire are immersed in a solution of sulphate of zinc, the direction of the current being (in the solution) from the upper to the lower electrode.



"I tested this a few days ago, using a glass tube eighteen inches long, filled with a saturated solution of sulphate of copper and closed by copper caps with wires attached.

"On connecting the wires with a very delicate Thomson's astatic galvanometer belonging to Prof. Halford, a very considerable deflection was produced (200 divisions) when the tube was held vertically, the direction of the deflection being reversed when the tube was reversed.

"If the tube, after being held vertically, was placed in a horizontal position, the deflection diminished, but several minutes elapsed before the index came to zero, which it eventually did. I cannot explain the time taken. I am now preparing to test the actual loss of weight of the upper electrode.

"I have the honour to be, Sir,
"Your obedient servant,
"F. J. PIRANI,
'Lecturer on Natural Philosophy and Logic,
University of Melbourne.

"P.S.—If the phenomenon has not been noticed before I shall be obliged if you will kindly communicate it to NATURE.
"F. J. P."

The Telephone

I HAVE been much interested in the communication by Dr. Rontgen on a telephonic alarum. During the past six or seven weeks, in investigating the phenomena of the telephone, chiefly as to the suggestions they offer regarding the mechanism of nervous transmission, I have frequently shown to friends the striking experiment described by Dr. Röntgen, and, amongst others, to Sir William Thomson. It has succeeded with Ut_2, Ut_3, and with numerous forks up to Ut_5, but, as stated by Dr. Rontgen, the best result was obtained with Ut_4. With those below this pitch the tone was feeble, whilst with those above it it was transient, in consequence of the difficulty of keeping the small fork going. With Ut_2, worked continuously by an electro-magnet, another fork of the same pitch sounded loudly and steadily. I have also been engaged in some endeavours to record on a moving surface the vibrations of the plate. These have been so successful as to show that it is only a question of delicate adjustment. In endeavouring to utilise one telephone by making several friends listen at once, I have found that by fixing the metal disc to a thin membrane over a small cavity filled with air, like a Koenig's capsule, and having a number of flexible leaden tubes connected with it, an ear placed at the end of each tube will hear distinctly. The Radiometer and its Lessons

PROF. OSBORNE REYNOLDS (vol. xviii. p. 121) appears to have done himself less than justice in the extracts he has sent you from his earlier papers, as representing his published views on the action of residual gas in radiometers. For the extracts do not suffice to constitute an explanation of this action, whereas the papers from which he makes the extracts contained what, if true, might have been an explanation of the action of residual gas, along with much else that is admittedly erroneous; and although those papers (the only ones published before mine) conclude with Prof. Reynolds's own expression of opinion that residual gas is not the cause of the force observed by Mr. Crookes.

He quotes three paragraphs. In two of these he recited the fundamental principle in the kinetic theory of gases which he sought to apply. To obtain an explanation of the phenomenon from this principle according to the method pursued by Prof. Reynolds, it was necessary for him (*a*) to establish a law connecting an excess of force perpendicular to the disc with a flow of heat in radiometers, and (*b*) to indicate agencies which could occasion a sufficient flow of heat. He quotes the passage in which he announced the result of his, as I believe, unsuccessful attempt to accomplish the former of these, but he omits the equally necessary passage in which he dealt with the latter. It will be found at page 407 of the *Proceedings* of the Royal Society, vol. xxii., and is couched in the following terms:—"It must be remembered that ϵ [which measures the outflow of heat] depends on the rate at which cold particles will come up to the hot surface, which is very slow when it depends only on the diffusion of the particles of the gas *inter se*, and the diffusion of the heat among them. It will be much increased by convection currents." If this passage, as was requisite, had been added to the extracts made by Prof. Reynolds, it would have brought his recent account of the views he had announced into conformity with my account of them.

In connection with this subject it should be observed that Prof. Osborne Reynolds has in express terms excluded from his explanation that which I believe to be the real agency which brings a sufficient supply of cold molecules up to the hot surface, for he states, in his letter to NATURE (vol. xvii., p. 27), that "it is incompatible with his explanation that the increase resulting from rarefaction in the mean length of the path of the gaseous molecules would favour the action." Now the polarisation of the gas depends on the ratio which this mean length bears to the interval between heater and cooler.

I cannot find anywhere in Prof. Osborne Reynolds's writings an explanation of the thing to be explained, viz., that the stress in a Crookes's layer is different in one direction from what it is at right angles to that direction. Let v be the component of the momenta of the molecules striking a square unit of the heater in the unit of time, resolved perpendicularly towards the heater; and let u be the corresponding normal component of their momenta from the heater, when they are thrown off. Then $u + v$ is the pressure on the heater. Now if u and v could result respectively from *unpolarised* motions in the gas, the momentum resolved parallel to the heater would be $\frac{1}{2}u + \frac{1}{2}v$ from left to right, with an equal momentum from right to left. Adding these we find $u + v$ the pressure of the gas parallel to the heater. This is equal to the normal pressure, and, therefore, under these circumstances, there would be no Crookes's force whatever. It is only when we take the polarisation of the gas into account that the momenta resolved parallel to the heater become different from $\frac{1}{2}u$ and $\frac{1}{2}v$.

Prof. Osborne Reynolds says that my views are at variance with results arrived at by Clausius and other discoverers in this branch of physics. I do not myself value appeals to authority in matters of science. But it so happens that here again it appears to be Prof. Reynolds who makes the mistake. Clausius, in his great memoir on the conduction of heat by gases, published in 1862 (*Phil. Mag.*, vol. xxiii. p. 529), warns his readers against the very error into which Prof. Reynolds seems to fall, and points out that there "are obvious limits" beyond which the laws he had discovered for the conduction of heat do not prevail, one of which limits is that the gas "must not be so expanded that the mean length of excursion of the molecules becomes so great that its higher powers cannot be neglected." Now it is just to this excepted case, to the Sprengel vacua experimented on by Mr. Crookes, that Prof. Osborne Reynolds applies the laws of conduction, and he then objects to my theory that it does not agree with the laws so misapplied. The phenomenon of Crookes's stress appears to come into existence precisely in Clausius's excepted case, viz., so soon as the ratio which the mean length of excursion of the molecules bears to the interval between heater and cooler, is such, that when multiplied by a function of the temperatures of the heater and cooler, its square is of appreciable magnitude in Clausius's equations. This may be experimentally secured either by placing the heater and cooler very close together, as in experiments upon spheroidal drops, or by excessively attenuating the gas so as to lengthen the free paths of the molecules sufficiently, as in radiometers. G. JOHNSTONE STONEY

Dublin, December 20

POSTSCRIPT, December 22.—I have just seen Prof. Schuster's letter (NATURE, vol. xvii. p. 143). Dr. Schuster will pardon me if I say that he has adopted a scarcely legitimate course in introducing into a discussion on priority his present reminiscence of one of the conversations about the radiometer which he held with his friend, Prof. Osborne Reynolds, two and a half years ago. The language in which he reports it is foreign to Prof. Reynolds's style of composition, so that we may conclude we are dealing with Dr. Schuster's words, and the words which occurred to him after he had read much else on the subject. No judicially-minded person would attach much weight even to a report of his own, drawn up under such circumstances, and all judicially-minded persons will regret its introduction here. Prof. Osborne Reynolds's reasoning proceeds on the hypothesis that the gas is not polarised. The only real question here is, Is Prof. Schuster prepared to maintain that this reasoning is correct?

Prof. Schuster, in reporting his reminiscences, first recites a kinetic principle which is quite consistent with there being as much force sideways as perpendicularly to the disc, and which therefore contains no explanation of the phenomenon; and when he comes to the first essential point, viz., that which requires him to show that "an increased pressure on the cold side of the vanes of a radiometer will not counterbalance the force acting on the blackened sides," all that he has to say on the subject is that "he does not think that such is the case!" This is the essential thing to be *proved* before the explanation can be accepted, and he recites experiments which show that it is essential.

Prof. Schuster concludes this part of his letter with the admission that "he does not see how [on his theory] an increase in the force can take place" as the exhaustion proceeds. So much the worse for the theory, since experiment indicates that such an increase in the force does take place. In proof of this I may allege, in addition to Mr. Crookes's experiments, several series of experiments made by Mr. Moss, one of the most judicially-minded, patient, and dexterous manipulators I have met with. The experiments were made with the apparatus described in a communication from him and myself, published last spring in the *Proceedings* of the Royal Society, and the effect of the convection current was with extreme care excluded in two ways—by placing the swinging disc where the influence of the convection current on it before and behind was balanced, and by observing the motions that arose before the convection current had time to reach the disc. Both methods concurred in showing that, as in Mr. Crookes's experiments, the force on the disc uniformly increased with increasing attenuation of the gas up to the limit to which we pushed the exhaustion. Mr. Crookes has shown that beyond that limit it begins to decrease. Prof. Schuster will do a real service to science if he will devote his great skill for some months to repeating these and other concurrent experiments, and either confirm them or point out why they should be set aside.

Prof. Schuster thinks that "any theory of the radiometer which makes the action depend on the comparatively large [? small] ratio of the mean free path to the dimensions of the vessel, must necessarily be wrong." Has not Prof. Schuster here overlooked the minuteness of the phenomenon which has to be accounted for? Spheroidal drops of less than a millimetre diameter are easily formed of several light liquids. The Crookes's stress which supports these is an excess of vertical stress over horizontal stress in the supporting layer of polarised gas, amounting to about the 12- or 15-thousandth part of the whole stress. This compares favourably with the minute ratio to which Prof. Schuster refers.

I will not at present enter on that part of Prof. Schuster's letter in which he criticises my published views on penetration, as he refers me to the researches of Messrs. Kundt and Warburg, which I have not yet seen. G. JOHNSTONE STONEY

Glaciation of Orkney

LAST spring Prof. Geikie informed me of a correspondence which was going on in the columns of NATURE as to the question whether the Orkney Islands bore evidence of having been glaciated. It was with much surprise that I heard that there could be any question on this point at all, but I refrained from submitting my opinion to the public—unhesitating though that opinion was—on account of my being then just about starting for my native county, and thus having an opportunity of very specially directing my attention anew to the matter. As the observations I then made *without exception* tended to confirm me in what really required no confirmation, I think I may now come forward as one who has for long known those islands, and who has made a very special geognostic survey of them, during many years. And I would first say, as regards the question, "whether Orkney does or does not give proof of having been covered by a great ice-sheet?" that I believe that no one who has educated his eye—not by looking at pictures in books, but among the rocks themselves—to the *apprehension* and recognition of the hill-contours of an ice-scalped country, would hesitate to declare Orkney to be such. Let such a one take his stand, at a sufficient altitude, anywhere along the north coast of Sutherland, with a scratched and polished boss under his feet, rolling up into rounded hillocks on every side, and sweep his eye from the two Ben Griams over to Hoy, and he could not but exclaim, "*There* is a country which has suffered sore."

In having to differ from Mr. Laing, I join issue with him on two points—boulders and foreign stones, and boulder-clay. I have also to corroborate Prof. Geikie as to glaciation near Stromness'; for I, during last summer, saw to the immediate north-west of Stromness a surface of gneiss, say ten feet by three, most unmistakably glaciated—both scratches and polishing being shown.

Now as regards "boulders and foreign stones." Mr. Laing will find—I wonder at his not knowing of it—about 100 yards to the west of the House of Saval, in Sanday, one of the finest boulders in Scotland. This boulder, of great size, consists of hornblendic gneiss; for long I was unable to identify it with any variety of the hornblendic gneiss of Sutherland; but this very year's work enables me to say that it is *very similar* to that of a locality near Durness. In all probability, however, its parent rock lay east, not west.

Another boulder I have heard of, but not seen; it was described to me under the name of the "Eagle Stone"; it lies upon the side of a hill in Westray, near Pierowall, and is said to be peculiar as a loose stone, both on account of its toppling position, its being different from any rock in Orkney, and from there being no rock near it.

As to there being "foreign stones" in Orkney, I shall only say that I have at present in my collection polished jaspers, picked up in rolled masses in Orkney; and that fragments of broken agates are found not unfrequently, on the hill tops and sides, in Hoy. These are quotations, *ex grege*.

Mr. Laing's very precise observations on the *clay beds*—let us call them—do call for special investigation.

If the conclusions arrived at by other observers are found to coincide with his—while they could not affect the ultimate decision as regards the ice-clad country—they certainly would strike these clay beds out of the category of boulder-clays. But, sir, I have seen these clays, and I did not see what Mr. Laing saw; and what I did observe leads me to doubt the correctness of his conclusions. For I found it to be a notable circumstance as regards these Orkney clay-beds that they are very markedly *clay*-beds; *i.e.*, that the amount of clay relatively to that of the stoney matter therein is very much greater than that of most boulder-clays.

Now this is a fact which saps the very foundation of Mr. Laing's observation—an abnormally argillaceous clay bed being the result of the disintegration of a normally siliceous sandstone is difficult to conceive. Nay more, although the cement of certain of the Orkney beds is silicate of alumina, forming the blue argillaceous flag, it is an unquestionable fact, that these flags do not disintegrate by the action of the weather. Even the Picts knew that when they built their Broughs thereof. Silicate of alumina is not affected by carbonated waters.

Upon—nearly all along—the west shore of Shapinsha there are cliffs—sea-cliffs of these clay beds, which lie *betwixt the rocks*, or the last visible rock, *and the sea*; that last rock is a red ferruginous loose-grained sandstone, with little or no cement, what there is being micaceous; the clay beds are ochre yellow. The disintegration of this rock never could have yielded these clay beds.

But Mr. Laing may argue that they resulted from the decay of an overlying argillaceous bed. The argument will not stand. Firstly, because the dip is the wrong way; the rock dips at a high angle to the east; the clay *slightly* caps it, and stands as a bank between its escarpment and the sea. Secondly, because a friable yellow freestone, destitute of argillaceous cement, should overlie the red beds. Thirdly, because on the other side of the bay where the argillaceous flags do appear they are quite permanent. Ice might *grind them up*—the "weather" does not rot them down. But here no clay beds are seen.

Finally, sir, I would request my talented countryman—whom I have great pleasure in breaking a lance with in this field—to consider how or why it is that these clay beds are found only *on one side* of the long depression which runs up the centre of the islands? M. FORSTER HEDDLE

University, St. Andrews, December 19, 1877

Northern Affinities of Chilian Insects

I THINK I may be allowed to express my surprise at Mr. McLachlan's statement that this subject has never yet been "even more than casually alluded to in works on geographical distribution," and is "*ignored in the principal ones;*" when I have devoted no less than six pages of my book on "The Geographical Distribution of Animals" (vol. ii. pp. 42-48) to a discussion of the main facts—quite as much as could be properly given to it in a general work. It is, however, well worthy of a detailed study, which I am very glad is being undertaken by so competent an entomologist. I hope Mr. McLachlan will endeavour to obtain collections of coleoptera and other orders of insects from the higher tropical Andes, where, I feel confident, some northern forms will also be found.

ALFRED R. WALLACE

Mr. Crookes and Eva Fay

A FEW words from myself seem to be called for by the recent letter of Mr. Crookes in reply to Prof. Carpenter, published in your journal. As far as I am concerned, the breach of etiquette complained of can only apply to my obtaining the publication of the letter Mr. Crookes addressed to me in the *Banner of Light*. The subsequent *facsimile* that appeared I am not in any way responsible for.

The part I took in the matter is very simple, and may be briefly explained as follows:—On Mrs. Fay's return from England to this country the genuineness of her mediumship was very much doubted, and was the subject of controversy not only in the spiritual journals, but in other papers as well. Having, whilst in England, satisfied myself that the manifestations were real, I defended her to the best of my ability, and on seeing it stated in the *Boston Herald* that Mr. Crookes had withdrawn his confidence in her, I thought it prudent to write to that gentleman, mentioning my reason for so doing. In due time I received a courteous reply, which I at once took to the *Banner* office, never dreaming that Mr. Crookes could have any possible objection to its publication after the articles he had himself published on the subject in the English journals. Months elapsed, when one day to my surprise I met with the *facsimile* letter in the *New York Daily Graphic*. On mentioning the subject to the editor of the *Banner* he also expressed surprise, and stated his inability to account for the publication of the *facsimile*. He at first was of opinion that I had taken the letter away and mislaid it; but on searching, the document was subsequently found in the office. Hereupon both Mr. Colby and myself wrote to the editor of the *Graphic*, requesting him to state how he obtained possession of the original letter, so as to get the *facsimile* prepared; but neither of us received a reply. I then got a gentleman residing in New York to call on the *Graphic* editor on the subject, and was informed that the said editor declined to say how he obtained possession of the letter. Thus the matter stands, and is as inexplicable today as it was at the time it happened.

I entirely exonerate the editor of the *Banner* and his associates from any complicity in the matter, and I trust Mr. Crookes, after this explanation, will see that his imputation against American honour is wholly unfounded.

The publication of the letter in the *Banner* I alone am answerable for; and as I explained in my letter to Mr. Crookes that my object was to meet a statement in a public journal, I of course thought that he must have felt that the reply he forwarded would in all probability be made public use of.

Boston, U.S.A., December 7, 1877 ROBERT COOPER

P.S.—Mr. Crookes errs in speaking of me as "a Boston gentleman." I am an Englishman temporarily located here.—R. C.

Philadelphia Diploma

IN NATURE, vol. xvii. p. 153, it is stated that "A 'Dr.' Harmuth, in Berlin, who received his diploma from Philadelphia, was lately sentenced to pay 300 marks for using the prefix publicly." It is but just to so old and respectable a university as that of Philadelphia to point out that "Dr." Harmuth's diploma could not have been genuine. So-called "Philadelphia degrees" of all sorts are sold by agents, but they have no connection with the University of Philadelphia, nor have they, at present, any connection with the city, though the author of this scandalous imposition once lived there and carried on a disreputable practice as a quack doctor. The public should still be on their guard against Bogus degrees, for diplomas purporting to issue from several American and German universities are still to be had, in some cases on examination *in absentia* and payment of the fee, in others by a money payment only.

C. M. INGLEBY

Valentines, December 26, 1877

Royal Dublin Society

IN justice to myself I beg to state that my function as editor of the Natural Science papers in the "Scientific Proceedings of the Royal Dublin Society" begins only with Part 2 of that journal, and that I had no knowledge whatever of the material contained in Part 1 until it had been printed and circulated. By publishing this I shall be greatly obliged.

ALEX. MACALISTER

Anatomical Museum, Trinity College, Dublin

The Meteor of November 23

I HAVE just seen Capt. Tupman's letter in NATURE (vol. xvii. p. 114). I can give a fairly accurate estimate of the direction of the meteor from Llandudno at the time it burst. Sitting in a lighted room my eye was attracted by a bright bar of light across the hearth-rug similar in shape to a gap in the Venetian blind caused by a broken tape. The light slowly faded out in about the same place, which was easily remembered. I listened intently for a report for perhaps about a minute, gave it up, and then heard what was somewhat like the report of a ship's gun at a short distance.

It was easy afterwards to estimate the direction of the light as two points west of (true) north, and thirty-five degrees above the horizon.

I regret that the time between the fading of the light and the report I can only guess very roughly. It may have been about two minutes.

T. S. PETTY

51, Boundary Road, N.W.

THE SUN'S MAGNETIC ACTION AT THE PRESENT TIME

PERHAPS no result in magnetism has excited so much interest as that which has connected the varying diurnal oscillation of the magnetic needle, and the frequency of the aurora polaris, with the spotted area of the sun's surface, in a common cycle of ten and a half years. Various investigations have been undertaken in order to determine whether other phenomena could not be found which would take a place in this chain.

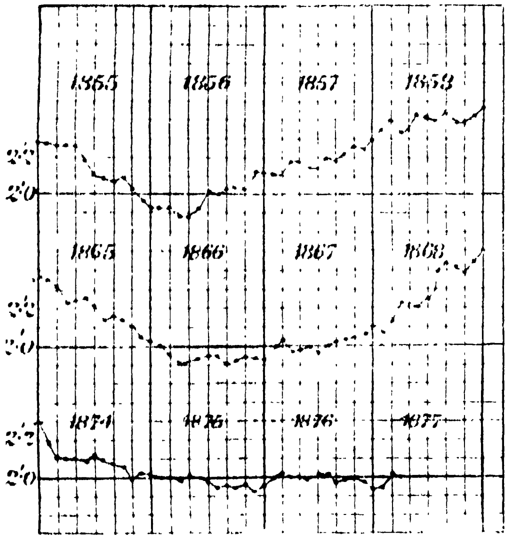
That the movements of the magnets and the corruscations of the aurora are due to the cause which produces the immense chasms in the sun's envelopes there can be little doubt; but we know nothing of the mode in which the sun acts on our earth to produce these effects, and we have reason to believe that this ignorance has prevented us hitherto from tracing to the same cause atmospheric variations which have been attributed altogether to the solar heating action.

Any facts, then, as to what the sun is doing at the present time with the earth's magnetism will not be without value, whether we regard the facts alone, or as connected with their hypothetical relations to atmospheric phenomena. It should always be remembered, however, that the variations of magnetic oscillations in the decennial period, shown at any one station on the earth's surface, agree generally with those shown over the whole globe, while the meteorological phenomena are so much affected by conditions of position that it is difficult to distinguish what is due to local and what to cosmic causes.

It is well known to those who have studied this subject, that the interval from the time when the sun has fewest, till that when he has most, spots has been less than that from the maximum to the minimum; and that the same fact has been observed in the case of the magnetic oscillations. The way in which the changes of the latter occur near the times of successive minima has not, however, been studied. The accompanying diagram will show this for the last three minima.

If we suppose that the mean diurnal movement of the magnetic needle is determined for each month, we obtain the amount of the oscillation or range; the mean of the ranges thus found for twelve successive months is represented by a point in the curves; thus the last point in the lowest curve represents the mean of the ranges for the twelve months, October, 1876, to September, 1877 (corresponding to April 1, 1877), as shown by the observations made in the Trevandrum Observatory (nearly on the magnetic equator). The point immediately preceding represents the mean range for the twelve months, September, 1876, to August, 1877, and so on for the other points.

If these curves are examined, it will be seen, that in the upper one the minimum is very clearly marked by two points corresponding to April 1 and May 1, 1856 (representing the mean ranges, October, 1855, to September, 1856, and November, 1855, to October, 1856), and that there is little difference in the rapidity with which the curve descends to, and ascends from, the minimum.



In the middle curve the epoch of minimum is by no means so distinctly marked; it occurs between the points for April 1 and September 1, 1866. There is also a considerable difference in the rapidity of variation in the descending and ascending branches of the curve. The descent is nearly as rapid as in the upper curve, but the ascent is very much slower.

In the lower curve, the lowest point is that for December 1, 1875, but it is even now, with points for a year and a half later, difficult to say whether this is the minimum or not, the point for January 1, 1877, being only 0'·02 (two-hundredths of a minute of arc) higher. In this curve the change of range in the diurnal oscillation is quite insignificant from November 1, 1874, to April 1, 1877, including the ranges from May 1, 1874, to September 30, 1877, an interval of three years and five months. If this result is confirmed by other observations, as I believe will be the case, no such constant state of the sun's magnetic action will have been observed since the last years of the eighteenth century.

The observations of sun-spots, even if they give as accurate a measure of the intensity of the cause as that obtained from the movements of our magnets, cannot be observed with the same continuity, nor be measured with the same precision; but I have little doubt they will confirm generally the result shown in the last curve, as they have in preceding cases.

With regard to the aurora borealis, the appearances seem to have been very rare during the last two winters. In the report by Capt. Sir G. Nares, on the Arctic expedition, he says that in the winter of 1875-76, "Light flashes of aurora were occasionally seen on various bearings, but most frequently passing through the zenith; none were of sufficient brilliancy to call for notice. The phenomena may be said to have been insignificant in the extreme, and, as far as we could discover, were totally unconnected with any magnetic or electric disturbance" (NATURE, vol. xv. p. 35).

In the twelve months including September, 1843, and August, 1844, including the epoch of minimum disturbance and of auroral frequency, I observed in the south of Scotland (in lat. 55° 35′) thirty appearances of the aurora, and from September, 1844, till the end of 1845, fifty-nine appearances were observed at this single station.[1] Making every allowance for the continuous watch over the magnetic instruments at the Makerstoun Observatory during these years, the difference between Capt. Sir G. Nares's result, in so high latitude, in 1875-76, and that for the south of Scotland, is very distinct. I ought to add, with reference to the apparent want of connection of the faint auroral appearances with the magnetic disturbance noticed by Sir G. Nares, that several of the auroræ observed by me were of the very faintest kind, mere "traces," as I have termed them, which I could never have remarked had I not been warned by *very slight* magnetic irregularities to examine the sky with the greatest attention. Again, in no case have I seen the faintest trace of an aurora without finding at the same time a corresponding irregularity in the movement of the force or declination magnet.

I am unacquainted with any observations of the aurora made in the British Isles during the last two winters;[2] I believe that no scientific institution exists in this country which makes the look-out for aurora throughout the night a definite portion of its work, and that all our knowledge of this phenomenon appears to be left to the chances of some one being out, at the hour of a display, sufficiently bright to attract his attention who will take the trouble to communicate his observation to a public journal.

JOHN ALLAN BROUN

P.S.—I have to thank Mr. A Buchan for kindly furnishing me with a note of the auroras seen at the stations of the Scottish Meteorological Society during the year 1876. These amounted to forty-two in number, twenty-six in the first half and sixteen in the second half of the year. The greater part were seen in the most northerly stations, including the Orkney, Shetland, and Farö Islands; nine only having been seen south of the Forth. I cannot, however, compare the total result from the hundred stations of the Society with that from the single southerly station of Makerstoun in 1844, since much depends on the nature of the watch kept in each case. It is, however, gratifying to find that so much attention is given at the stations of that highly useful scientific body, the Scottish Meteorological Society, to the observation of this phenomenon.

December 31, 1877

[1] "General Results of the Makerstoun Observations," p. lxxv., *Trans. Roy. Soc Edin*, Part 2, vol. xix.

[2] I do not omit Mr Kinahan's account of "auroric lights," which he saw so frequently in the winter of 1876-77, and which he considered a species of aurora borealis (NATURE, vol. xv. p. 334), as I think there must have been some mistake as to the nature of these lights. He says they were "very common and brilliant during 'the dark days' of December, a few hours before dawn (about five o'clock)." The aurora borealis is very rarely seen at five A.M. in this country. In the two years, 1844 and 1845, during which the aurora was sought for at Makerstoun every hour of the night, it was observed on seventy-seven nights on an average of nearly three hours each night, but it was seen only twice so early, and that with a bright or brilliant aurora which remained during five hours on the first occasion, and from six P.M. [illegible] six A.M. on the second. I cannot say, also, that I have ever seen part of the phenomenon described by Mr. Kinahan, and I had hoped that some other observer in Ireland would have confirmed his observations, which if exact, would be most important, especially as made so frequently at the epoch of minimum.

THE "CHALLENGER" IN THE ATLANTIC[1]

II.

IT still seems but the other day when every zoologist believed with Edward Forbes that not very far below the surface of the sea there existed a region where life was unknown, or where at the most, if it existed it showed but a few sparks, which only served "to mark its lingering presence;" and yet even when Forbes was writing thus, Sir John Ross had brought up from some 800 fathoms deep in Baffin's Bay, "a beautiful *Caput medusæ*," and the present president[2] of the Royal Society had written (August 31, 1845), "It is probable that animal life exists at a very great depth—in the ocean." "On one occasion, off Victoria Land, between the parallels of 71° and 78° S.L., the dredge was repeatedly employed, once with great success at 380 fathoms," and "on another occasion the sounding-line brought up distinct traces of animal life from a depth of 550 fathoms." The history, however, of the subject, is to be found recorded in Sir Wyville Thomson's "Depths of the Sea," and we only here refer to it to remind the reader how completely changed are the general ideas on this subject; and we learn without surprise that "the most prominent and remarkable biological result of the *Challenger's* voyage is the final establishment of the fact that the distribution of living [animal] beings has *no depth limit*, but that animals of all the marine invertebrate classes, and probably fishes also, exist over the whole of the flora of the ocean;" but although life is thus universally extended, probably the number of species as well as of individuals diminishes after a certain depth is reached. This distribution of animal life depends in a marked degree either upon the nature of the sea-bottom or upon the conditions which modify the nature of that bottom. The fauna at great depths was found to be remarkably uniform, and the distribution area seemed to depend mainly on the maintenance of a tolerably uniform temperature. It is curious to note that the families which are peculiarly characteristic of the abyssal fauna, contain a larger number of species and individuals, and these are larger and more fully developed in the Antarctic Ocean, than they are in the Atlantic and the North Pacific.

Though the task of determining the various animal forms procured will occupy a number of specialists for several years, still we have several glimpses of the riches of the ocean fauna in these two volumes. Among these the pretty Hexactinellid sponges, the stalked crinoids, and the echinoids seem to hold foremost places. The stalked crinoids with their lily-like forms are the most remarkable of these, not only on account of their extreme rarity, but also on account of the special interest of their relation to many well-known fossil forms. Of one of these fine forms we give the accompanying illustration (Fig. 3). It was dredged from a depth of about 400 fathoms, near the Island of San Miguel. It belongs to the genus *Pentacrinus*, and has been called after Capt. Maclear, R.N., the commander of the *Challenger*. The lily-shaped head is about 3½ inches in height, and the stalk may have been several inches longer. The scientific description of such a form must necessarily be very technical, and not easily to be understood by the general reader, who, however, cannot fail to get a correct idea of its general form and

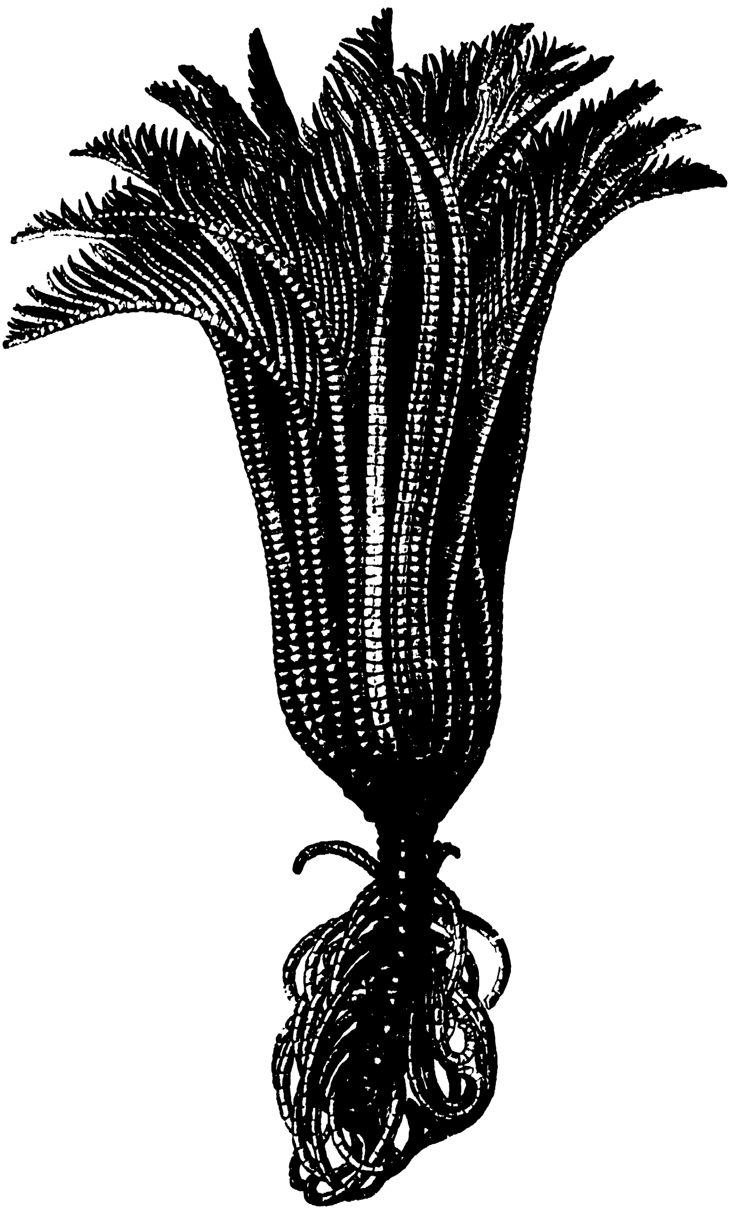

FIG. 3.—*Pentacrinus maclearanus*, Wyville Thomson. Slightly enlarged.

[1] "The Voyage of the *Challenger*. The Atlantic: a Preliminary Account of the General Results of the Exploring Voyage of H.M.S. *Challenger* during the Year 1873 and the Early Part of the Year 1876." By Sir C. Wyville Thomson, Knt., LL.D., F.R.SS. L. and E., &c., Regius Professor of Natural History in the University of Edinburgh, and Director of the Civilian Scientific Staff of the *Challenger* Exploring Expedition. Two volumes. Published by Authority of the Lords Commissioners of the Admiralty. (London: Macmillan and Co., 1877.) Continued from p. 148.

[2] Sir Joseph Hooker, C.B.

appearance from the illustration. The special volume in which the whole group of these lily-like starfish will be described is, we understand, to be from the pen of Sir Wyville Thomson.

Though the zoological treasures obtained by dredging were often very great, yet sometimes this often prolonged operation ended in utter disappointment; for example:—The vessel was on her way from Bahia to the Cape, when, on October 2, "we saw our first albatross sailing round the ship with that majestic careless flight which has been our admiration and wonder ever since; rising and sinking, and soaring over us in all weathers, utterly regardless of the motion of the ship, and without the slightest apparent effort. I have often watched these glorious birds for hours from the bridge, and notwithstanding all we know or think we know about the mechanics of flight, to the last I felt inclined to protest that for so heavy a bird to support itself motionless in the air, and perform its vigorous evolutions without a perceptible movement of the wings, was simply impossible by any mechanical means of which we have the least conception.

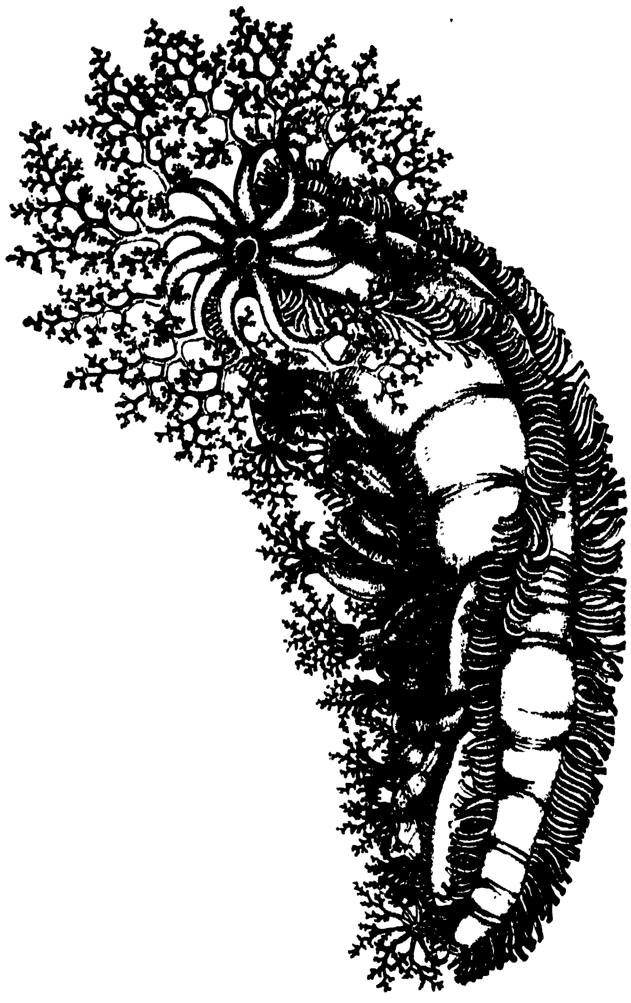

FIG. 4.—*Cladodactyla crocea*, LESSON. Stanley Harbour, Falkland Islands. Natural size.

"On the 3rd we sounded in 2,350 fathoms with a bottom of red mud, still due apparently in a great degree to the South American rivers, and a bottom temperature of 0°·8 C. The trawl was lowered, and on heaving in, it came up apparently with a heavy weight, the accumulators being stretched to the utmost. It was a long and weary wind-in, on account of the continued strain; at length it came close to the surface, and we could see the distended net through the water; when, just as it was leaving the water, and so greatly increasing its weight, the swivel between the dredge-rope and the chain gave way, and the trawl with its unknown burden quietly sank out of sight. It was a cruel disappointment—every one was on the bridge, and curiosity was wound up to the highest pitch; some vowed that they saw resting on the beam of the vanishing trawl the white hand of the mermaiden for whom we had watched so long in vain; but I think it is more likely that the trawl had got bagged with the large sea-slugs which occur in some of these deep dredgings in large quantity, and have more than once burst the trawl net."

Among the interesting creatures met with living, not in the depths of the sea, but in this instance living amid the fronds of one of the larger algæ, was a Holothuroid, of which we have the following account:—

"The weather while we were at the Falklands was generally cold and boisterous, and boat-work was consequently uncomfortable and frequently impracticable, except in the shallow water within the harbour; we had, however, two or three days' dredging in the pinnace, and made a pretty fair account of the submarine inhabitants of our immediate neighbourhood. *Macrocystis pyrifera*, the huge tangle of the Southern Seas, is very abundant in Stanley Harbour, anchored in about ten fathoms, the long fronds stretching for many yards along the surface and swaying to and fro with the tide. Adhering to the fronds of macrocystis there were great numbers of an elegant little cucumber-shaped sea-slug (*Cladodactyla crocea*, Lesson, sp.), from 80 to 100 mm. in length by 30 mm. in width at the widest part, and of a bright saffron-yellow colour. The mouth and excretory opening are terminal; ten long, delicate, branched oral tentacles, more resembling in form and attitude those of *Ocnus* than those of the typical *Cucumariæ*, surround the mouth; the perisom is thin and semi-transparent, and the muscular bands, the radial vessels, and even the internal viscera can be plainly seen through it. The three anterior ambulacral vessels are approximated, and on these the tentacular feet are numerous and well developed, with a sucking-disc supported by a round cribriform calcareous plate, or more frequently by several wedge-shaped radiating plates arranged in the form of a rosette; and these three ambulacra form together, at all events in the female, a special ambulatory surface.

"The two ambulacral vessels of the 'bivium' are also approximated along the back, and thus the two interambulacral spaces on the sides of the animal, between the external trivial ambulacra and the ambulacra of the bivium, are considerably wider than the other three; consequently, in a transverse section, the ambulacral vessels do not correspond with the angles of a regular pentagon, but with those of an irregular figure in which three angles are approximated beneath and two above. In the female the tentacular feet of the dorsal (bivial) ambulacra are very short; they are provided with sucking-discs, but the calcareous support of the suckers is very rudimentary, and the tubular processes are not apparently fitted for locomotion. In the males there is not so great a difference in character between the ambulacra of the trivium and those of the bivium; but the tentacles of the latter seem to be less fully developed in both sexes, and I have never happened to see an individual of either sex progressing upon, or adhering by, the water-feet of the dorsal canals.

"In a very large proportion of the females which I examined, young were closely packed in two continuous fringes adhering to the water-feet of the dorsal ambulacra. The young were in all the later stages of growth, and of all sizes from 5 up to 40 mm. in length; but all the young attached to one female appeared to be nearly of the same age and size. Some of the mothers with older families had a most grotesque appearance—their bodies entirely hidden by the couple of rows, of a dozen or so each, of yellow vesicles, like ripe yellow plums ranged along their backs, each surmounted by its expanded crown of oral tentacles; in the figure the young are represented about half-grown. All the young I examined were miniatures of their parents; the only marked difference was that in the young the ambulacra of the bivium were quite rudimentary—they were externally represented only by bands of a somewhat darker orange than the rest of the surface, and by lines of low papillæ in the young of larger growth; the radial vessels could be well seen through the transparent body-wall; the young attached themselves by the tentacular feet of the trivial ambulacra, which are early and fully developed.

"We were too late at the Falklands (January 23) to see the process of the attachment of the young in their nursery, even if we could have arranged to keep specimens alive under observation. There can be little doubt that, according to the analogy of the class, the eggs are impregnated either in the ovarial tube or immediately after their extrusion, that the first developmental stages are run through rapidly, and that the young are passed back from the ovarial opening, which is at the side of the mouth, along the dorsal ambulacra, and arranged in their places by the automatic action of the ambulacral tentacles themselves."

One other illustration we take, this time from an animal living in the surface water, though it sinks, when dead, to the bottom of the sea (Fig. 5).

"*Hastigerina murrayi* is very widely distributed on the surface of warm seas, more abundant, however, and of larger size in the Pacific than in the Atlantic. The shell consists of a series of eight or nine rapidly enlarging inflated chambers coiled symmetrically on a plane; the shell-wall is extremely thin, perfectly hyaline, and rather closely perforated with large and obvious pores. It is beset with a comparatively small number of very large and long spines. The proximal portion of each spine is formed of three laminæ, delicately serrated along their outer edges, and their inner edges united together. The spines, when they come near the point of junction with the shell, are contracted to a narrow cylindrical neck, which is attached to the shell by a slightly expanded conical base. The distal portion of the spine loses its three diverging laminæ, and becomes flexible and thread-like. The sarcode is of a rich orange colour from included highly-coooured oil-globules.

"On one occasion in the Pacific, when Mr. Murray was out in a boat in a dead calm collecting surface creatures, he took gently up in a spoon a little globular gelatinous mass with a red centre, and transferred it to a tube. This globule gave us our first and last chance of seeing what a pelagic foraminifer really is when in its full beauty. When placed under the microscope it proved to be a *Hastigerina* in a condition wholly different from anything which we had yet seen. The spines, which were mostly unbroken, owing to its mode of capture, were enormously long, about fifteen times the diameter of the shell in length; the sarcode, loaded with its yellow oil-cells, was almost all outside the shell, and beyond the fringe of yellow sarcode the space between the spines, to a distance of about twice the diameter of the shell all round, was completely filled up with delicate *bullæ*, like those which we see in some of the Radiolarians, as if the most perfectly transparent portion of the sarcode had been blown out into a delicate froth of bubbles of uniform size. Along the spines fine double threads of transparent sarcode, loaded with minute granules, coursed up one side and down the other, while between the spines independent thread-like pseudopodia ran out, some of them perfectly free, and others anastomosing with one another or joining the sarcodic sheaths of the spines, but all showing the characteristic flowing movement of living protoplasm."

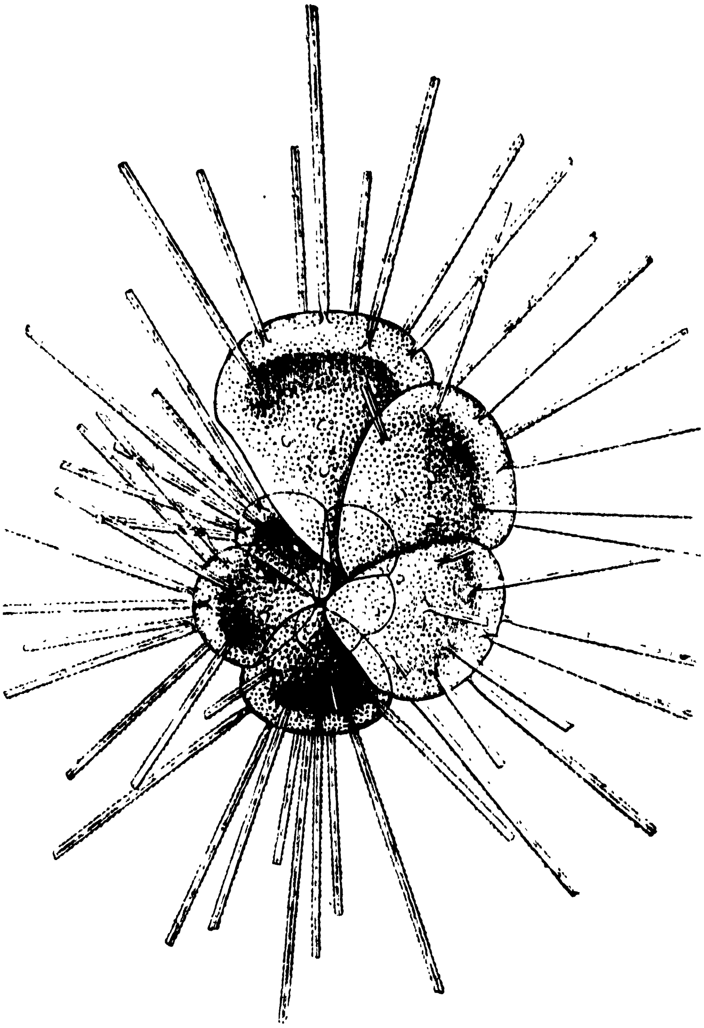

FIG. 5.—*Hastigerina murrayi*, Wyville Thomson From the surface. Fifty times the natural size.

It would be easy to extend our notice on the animal forms alluded to, but our space forbids. It is curious that no vegetable life seems to have been met with in depths below 100 fathoms. "No plants live, so far as we know, at great depths in the sea; and it is in all probability essentially inconsistent with their nature and mode of nutrition that they should do so." But parasitic alga have been detected in some of the deep-sea corals, and we are a little surprised to see the position of the diatoms queried; surely their plant affinities cannot now be discussed, and without these little plants we fancy some of the plant-eating deep-sea forms of animal life would be badly off. Holothuroids are especially fond of them.

The following general conclusions are arrived at:—

"1. Animal life is present on the bottom of the ocean at all depths.

"2. Animal life is not nearly so abundant at extreme as it is at more moderate depths; but, as well-developed members of all the marine invertebrate classes occur at all depths, this appears to depend more upon certain causes affecting the composition of the bottom deposits, and of the bottom water involving the supply of oxygen, and of carbonate of lime, phosphate of lime, and other materials necessary for their development, than upon any of the conditions immediately connected with depth.

"3. There is every reason to believe that the fauna of deep water is confined principally to two belts, one at and near the surface, and the other on and near the bottom; leaving an intermediate zone in which the larger animal forms, vertebrate and invertebrate, are nearly or entirely absent.

"4. Although all the principal marine invertebrate groups are represented in the abyssal fauna, the relative proportion in which they occur is peculiar. Thus Mollusca in all their classes, Brachyourous Crustacea, and Annelida, are on the whole scarce; while Echinodermata and Porifera greatly preponderate.

"5. Depths beyond 500 fathoms are inhabited throughout the world by a fauna which presents generally the same features throughout; deep-sea genera have usually a cosmopolitan extension, while species are either universally distributed, or, if they differ in remote localities, they are markedly representative, that is to say, they bear to one another a close genetic relation.

"6. The abyssal fauna is certainly more nearly related than the fauna of shallower water to the faunæ of the tertiary and secondary periods, although this relation is not so close as we were at first inclined to expect, and only a comparatively small number of types supposed to have become extinct have yet been discovered.

"7. The most characteristic abyssal forms, and those which are most nearly related to extinct types, seem to occur in greatest abundance and of largest size in the southern ocean; and the general character of the faunæ of the Atlantic and of the Pacific gives the impression that the migration of species has taken place in a northerly direction, that is to say, in a direction corresponding with the movement of the cold under-current.

"8. The general character of the abyssal fauna resembles most that of the shallower water of high northern and southern latitudes, no doubt because the conditions of temperature, on which the distribution of animals mainly depends, are nearly similar."

These volumes form a distinct contribution to Science, and will certainly be welcomed by the scientific worker; and their interest to the general reader, who can pass over the few technical descriptions of the new forms, will be scarcely at all less.

THE MODERN TELESCOPE[1]

III.

We know that both with object-glasses and reflectors a certain amount of light is lost by imperfect reflection in the one case, and by reflection from the surfaces and absorption in the other; and in reflectors we have generally two reflections instead of one. This loss is to the distinct disadvantage of the reflector, and it has been stated by authorities on the subject, that, light for light, if we use a reflector, we must make the aperture twice as large as that of a refractor in order to make up for the loss of light due to reflection. But Dr. Robinson thinks that this is an extreme estimate; and with reference to the four-foot reflector now in operation at Melbourne, and of which mention has already been made, he considers that a refractor of 33·73 inches aperture would be probably something like its equivalent if the glass were perfectly transparent, which is not the case.

On the assumption, therefore, that no light is lost in transmission through the object-glass, Dr. Robinson estimates that the apertures of a refractor and a reflector of the Newtonian construction must bear the relation to each other of 1 to 1·42. In small refractors the light absorbed by the glass is small, and therefore this ratio holds approximately good, but we see from the example just quoted how more nearly equal the ratio becomes on an increase of aperture, until at a certain limit the refractor, aperture for aperture, is surpassed by its rival, supposing Dr. Robinson's estimate to be correct. But with specula of silvered glass the reflective power is much higher than that of speculum metal; the silvered glass being estimated to reflect about 90 per cent.[1] of the incident light, while speculum metal is estimated to reflect about 63 per cent.; but be these figures correct or not, the silvered surface has undoubtedly the greater reflective power; and, according to Sir J. Herschel, a reflector of the Newtonian construction utilises about seven-eighths of the light that a refractor would do.

In treating of the question of the future of the telescope, we are liable to encroach on the domain of opinion, and go beyond the facts vouched for by evidence, but there are certain guiding principles which are well worthy of consideration. These have lately been discussed by Mr. Howard Grubb in a paper "On Great Telescopes of the Future." We shall take up his points *seriatim*, premising that in the two classes of telescopes, refractors and reflectors, each possesses some advantages over the other.

We may conveniently consider first the advantages which the refractor has over the reflector.

First, there is less loss of light with the former than with the latter, *as a rule*, hence for equal "space-penetrating power" the aperture of the reflector must be greater. This condition gives us a greater column of air and consequently greater atmospheric disturbance.

"The refractor having a tube closed at both ends, and the reflector being open at the upper end, the condition of air-currents is quite different in the two cases, to the disadvantage of the reflector, for in it the upper end being open, there is nothing to prevent currents of hot and cold air up and down the tube, and in and out of the aperture, and for this reason great advantage has been

---

[1] Continued from p. 187.

[1] Sir John Herschel, in his work on the telescope, gives the following table of reflective powers:—

After transmission through one surface of glass not in contact with any other surface	0·957
After transmission through one common surface of two glasses cemented together	1·000
After reflection on polished speculum metal at a perpendicular incidence	0·632
After reflection on polished speculum metal at 45° obliquity...	0·690
After reflection on pure polished silver at a perpendicular incidence	0·905
After reflection on pure polished silver at 45° obliquity ...	0·910
After reflection on glass (external) at a perpendicular incidence	0·043

The effective light in reflectors (irrespective of the eye piece.) is as follows:—

Herschelian (Lord Rosse's speculum metal)	A. 0·632
Newtonian (both mirrors ditto)	B. 0·436
Do (small mirror or glass prism)...	C. 0·632
Gregorian or Cassegrain	D. 0·399
The same telescopes, all the metallic reflections being from pure silver	A. 0·905 B. 0·824 C. 0·905 D. 0·819

found in ventilating the tubes, *i.e.* making it of some open-work construction, in order that the air may pass through and across and remove currents of differing temperatures. This difficulty is not felt with refractors; but, curious to say, in the largest refractor at present in existence (the Washington 26-inch), Prof. Newcomb informs me that considerable inconvenience is felt sometimes from the outside of the object-glass cooling down more quickly in the evening than the inside, which produces a decided effect on the spherical aberration, and injures temporarily the otherwise fine definition. He consequently recommends the use of lattice or ventilated tubes for very large refractors. If this be found necessary, this advantage of the refractor vanishes."

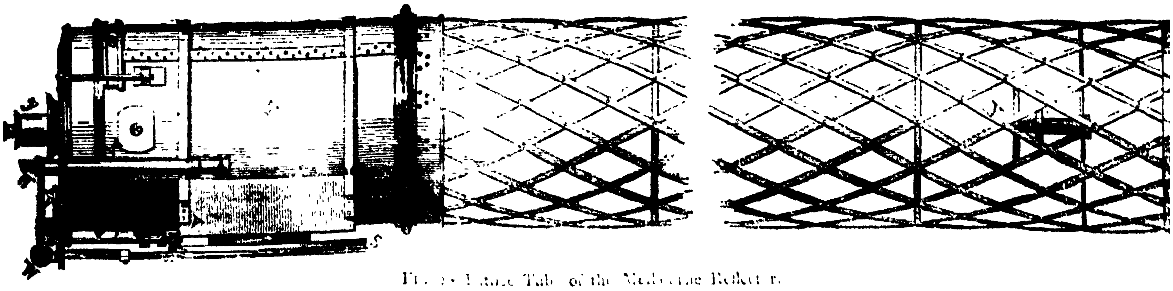

Fig. 2.—Lattice Tube of the Melbourne Reflector.

But there is another nice point concerning this larger aperture which has to be considered.

We may set out with observing that the light-grasping power of the reflector varies as the square of the aperture multiplied by a certain fraction representing the proportion of the amount of reflected light to that of the total incident rays. On the other hand the power of the refractor varies as the square of the aperture multiplied by a certain fraction representing the proportion of transmitted light to that of the total incident rays. Now in the case of the reflector the reflecting power of each unit of surface is constant whatever be the size of the mirror, but in that of the refractor *the transmitting power decreases with the thickness of the glass*, rendered requisite by increased size. Although for small apertures the transmitting power of the refractor is greater than the reflecting power of the reflector, still it is obvious that on increasing the size a stage must be at last reached when the two rivals become equal to each other. This limit has been estimated by Dr. Robinson to be 35·435 inches, a size not yet reached by our opticians by some ten inches, but object-glasses are increasing inch by inch, and it would be rash to say that this size cannot be reached within perhaps the lifetime of our present workers. However this may be we can say with safety that up to the present limit of size produced, refractors have the advantage in light-grasping power, and it is also a question whether with increase of thickness in the glass there will not be such an increase in the purity of material and polish as to keep the loss by transmission at its present value. Any one who has a Tully and a Cooke object-glass, by placing them side by side on a clean sheet of paper, will be able to see how our modern opticians have already reduced the loss by transmission.

The next point worthy of attention is the question of permanence of optical qualities. Here the refractor undoubtedly has the advantage. It is true that the flint glass of some object-glasses, chiefly those produced in Germany, gets attacked by a sort of tarnish, still that is not the case generally, while on the other hand, metallic mirrors often become considerably dimmed after a few months of use, the air of a town seeming to be fatal to them, and although repolishing is not a matter of any great difficulty in the hands of the maker, still it is a serious drawback to be obliged to return mirrors for this purpose. There are, however, some exceptions to this, for there are many small mirrors in existence whose polish is good after many years of continuous use, just as on the other hand there are many object-glasses whose polish has suffered in a few years, but these are exceptions to the rule. The same remarks apply to the silvered glass reflectors, for although the silvering of small mirrors is not a difficult process, the matter becomes exceedingly difficult with large surfaces, and indeed at present large discs of glass, say of four or six feet diameter, can rarely be produced. If, however, a process should be discovered of manufacturing these discs satisfactorily and of silvering them, there are objections to them on the grounds of the bad conductivity of glass, whereby changes of temperature alter the curvature, and there is also a great tendency for dew to be deposited on the surface.

With regard to the general suitability for observatory work this depends upon the kind of work required, whether for measuring positions, as in the case of the transit instrument, where permanency of mounting is of great importance, or for physical astronomy, when a steady image for a time only is required. For the first purpose the refractor has decidedly the advantage, as the object-glass can be fixed very nearly immovably in its cell, whereas its rival must of necessity, at least with present appliances, have a small, yet in comparison considerable, motion.

The difficulty of mounting mirrors, even of large size, has now been got over very perfectly. This difficulty does not occur in the mounting of object-glasses of sizes at present in use, but when we come to deal with lenses of some thirty inches diameter, the present simple method will in all probability be found insufficient, but we anticipate that one will be adopted which will allow the permanent position of the object-glass to be retained.

J. Norman Lockyer

(*To be continued.*)

OUR ASTRONOMICAL COLUMN

The Comet of 1106.—In Mr. Williams's account of the object observed by the Chinese in this year, and called a comet by Ma Twan Lin, we find the following note:—"This appears to have been a large meteor, as it seems to have been seen for a short time only." It is probable that the author had not compared Pingré's description of the motion of the comet, which was certainly observed in Europe early in the year, or he would have seen that in all likelihood, notwithstanding Ma Twan Lin's account reads as if it referred to a temporary phenomenon, the Chinese really observed the bright comet recorded by the European historians. We are told that in the fifth year of the epoch Tsung Ning, on day Woo Seuh of the first moon (1106, Feb. 10) a comet appeared in the west; it was like a great Pei Kow (a kind of measure). The luminous envelope was scattered; it appeared like a broken-up star. It was sixty cubits in length and three cubits in breadth. Its direction was to the north-east; it passed through Kwei, Lew, Wei, Maou, and Peih, which are sidereal divisions determined according to Biot by the stars β Andromedæ, β Arietis, α Muscæ, η Tauri, and ε Tauri respectively. "It then entered into the clouds, and was no more seen." Gaubil's manuscript, used by Pingré, assigns precisely the same course.

European historians relate that on February 4 (or according to others on the following day) a star was seen which was distant from the sun only "a foot and a half;" Matthew Paris and Matthew of Westminster call this star a comet. On February 7 a comet, properly so called, was discovered in Palestine in "that part of the sky where the sun sets in winter," its ray had "the whiteness of snow," and extended to the commencement of the sign Gemini, below the constellation Orion. As Pingré points out the comet must at this time have had a south latitude, and, considering the sun's position, could not be less advanced than 10° or 12° of Pisces to have been seen in the evening after sunset. The comet subsequently passed by west to north-west, the tail directed to that part of the sky between the north and the east; the comet was visible until the middle of the night, and "shone during twenty-five days in the same manner at the same hour;" as one writer states, it had a real motion from west to east. The length of the comet's appearance is variously given; an eye-witness says that the most piercing sight could hardly distinguish it after fifty days, and a manuscript consulted by Pingré, in the Bibliothèque de Sainte-Geneviève, of the thirteenth century at latest, mentions fifty-six days for the duration of visibility.

The comet of 1106 long attracted attention from the circumstance of Halley having identified it as the famous comet of 1680, an idea which was first disputed by Dunthorne, on the authority of a manuscript preserved in one of the College libraries at Cambridge, which gives the comet's track from the beginning of the sign Pisces (on February 7 as Dunthorne reads) in the order of the signs to the commencement of Cancer, which agrees closely with the path recorded by the Chinese. He considered that this track "quite overbalanced the probability of the identity of the comet with that of 1680"—and this view has been confirmed by subsequent calculation. Again, when astronomers were searching for earlier accounts which might refer to the great comet of 1843, first detected at noon-day on the date of its perihelion passage, this comet of 1106 was fixed upon by MM. Laugier and Mauvais, as probably identical with it, several of the circumstances mentioned above being overlooked by them, particularly the fact of the comet having been observed so long in the northern part of the heavens, where it is impossible that the comet of 1843 could be located.

On carefully weighing the scanty evidence afforded by the records of the time, it appears likely that the elements of the comet of 1106 bore some resemblance to those of the great comet of 1618 (Pingré's third comet), the inclination being smaller.

THE SATELLITES OF MARS.—Both of the newly-discovered satellites of Mars were observed during September with the 12-inch equatorial of the Morrison Observatory, Glasgow, Missouri, by Mr. Pritchett. On September 7 the two satellites could be seen with the planet entirely in the field, and were very distinct when it was shut out of it, and on September 10 and 13, the inner one was easily observed. The outer satellite was again estimated to be of the fourteenth magnitude. The observations of this satellite were made with wires faintly illuminated with a red light; for observations of the inner one the light of the planet sufficed Unfavourable skies prevented any observations in October, though Mr. Pritchett thinks the satellites might have been well followed during that month.

COLOURED DOUBLE STARS.—In Sir John Herschel's seventh catalogue of double stars from the sweeps with the 20-feet reflector is one the position of which identifies it with Σ 724, and the note attached runs thus: "A very curious double star, the small star is very red." The observation belongs to sweep No. 121, for the epoch 1828·05. Struve measured this object in 1829, but says nothing respecting the colours of the components, which he estimated on his scale 8·7 and 10·0. In 1829·85 the angle was 241·5°, and the distance 6·86″. Has any one confirmed Sir John Herschel's observation on the colour of the smaller star? The position for 1878·0 is in R.A. 5h. 33m. 30s., N.P.D. 79° 5′·5.

In *Memorie del' Osservatorio del Collegio Romano*, 1857-59, p, 173, Secchi mentions a wide double star, which is called *nova*, and is thus measured:—

1856·63 Pos. 335°·25 Dist. 23″·83 { Components 7m. and 8m. A red, B blue.

He has the additional remark, "*Colori superbi.*" This object would appear to be formed by Nos. 3743 and 3744 of Zone + 37° of the *Durchmusterung*; positions for 1855·0:—

		h m.		° ′
3743	R.A.	19 58 23·5	N.P.D.	52 4·1
3744	„	19 58 25·5	„	52 4·7

THE TALKING PHONOGRAPH[1]

MR. THOMAS A. EDISON recently came into this office, placed a little machine on our desk, turned a crank, and the machine inquired as to our health, asked how we liked the phonograph, informed us that *it* was well, and bid us a cordial good night. These remarks were not only perfectly audible to ourselves, but to a dozen or more persons gathered around, and they were produced by the aid of no other mechanism than the simple little contrivance explained and illustrated below.

The principle on which the machine operates we recently explained quite fully in announcing the discovery. There is, first, a mouth-piece, A, Fig. 1, across the inner orifice of which is a metal diaphragm, and to the centre of this diaphragm is attached a point, also of metal. B is a

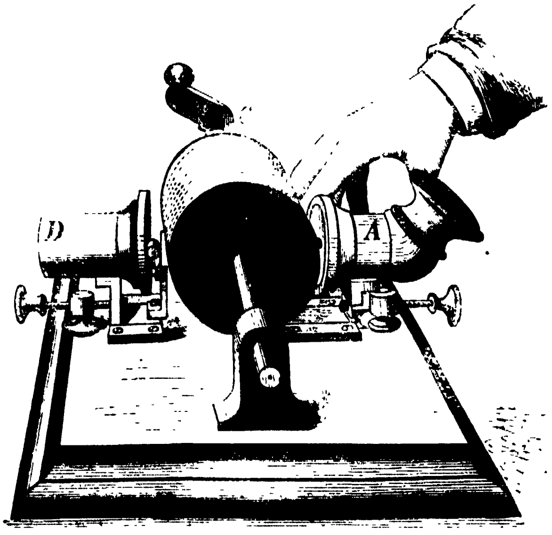

FIG. 1.

---

[1] From the *Scientific American* of December 22, 1877.

brass cylinder supported on a shaft which is screw-threaded, and turns in a nut for a bearing, so that when the cylinder is caused to revolve by the crank, C, it also has a horizontal travel in front of the mouthpiece, A. It will be clear that the point on the metal diaphragm must, therefore, describe a spiral trace over the surface of the cylinder. On the latter is cut a spiral groove of like pitch to that on the shaft, and around the cylinder is attached a strip of tinfoil. When sounds are uttered in the mouth-piece, A, the diaphragm is caused to vibrate, and the point thereon is caused to make contacts with the tinfoil at the portion where the latter crosses the spiral groove. Hence, the foil, not being there backed by the solid metal of the cylinder, becomes indented, and these indentations are necessarily an exact record of the sounds which produced them.

It might be said that at this point the machine has already become a complete phonograph or sound writer, but it yet remains to translate the remarks made. It should be remembered that the Marey and Rosapelly, the Scott or the Barlow apparatus, which we recently described, proceed no further than this. Each has its own system of caligraphy, and after it has inscribed its peculiar sinuous lines, it is still necessary to decipher them. Perhaps the best device of this kind ever contrived was the preparation of the human ear made by Dr. Clarence J. Blake, of Boston, for Prof. Bell, the inventor of the telephone. This was simply the ear from an actual subject, suitably mounted, and having attached to its drum a straw, which made traces on a blackened rotating cylinder. The difference in the traces of the sounds uttered in the ear was very clearly shown. Now there is no doubt that by practice and the aid of a magnifier, it would be possible to read phonetically Mr. Edison's record of dots and dashes, but he saves us that trouble by literally making it read itself. The distinction is the same as if, instead of perusing a book ourselves we drop it into a machine, set the latter in motion, and, behold! the voice of the author is heard repeating his own composition.

FIG. 2.

The reading mechanism is nothing but another diaphragm held in the tube D on the opposite side of the machine, and a point of metal which is held against the tin foil on the cylinder by a delicate spring. It makes no difference as to the vibrations produced, whether a nail moves over a file or a file moves over a nail, and in the present instance it is the file or indented foil strip which moves, and the metal point is caused to vibrate as it is affected by the passage of the indentations. The vibrations, however, of this point must be precisely the same as those of the other point which made the indentations, and these vibrations, transmitted to a second membrane, must cause the latter to vibrate similar to the first membrane, and the result is a synthesis of the sounds which, in the beginning, we saw, as it were, analysed.

In order to exhibit to the reader the writing of the machine which is thus automatically read, we have had a cast of a portion of the indented foil made, and from this the dots and lines in Fig. 2 are printed in, of course, absolute facsimile, excepting that they are level instead of being raised above or sunk beneath the surface. This is a part of the sentences, "How do you do?" and "How do you like the phonograph?" It is a little curious that the machine pronounces its own name with especial clearness. The crank handle shown in our perspective illustration of the device does not rightly belong to it, and was attached by Mr. Edison in order to facilitate its exhibition to us.

In order that the machine may be able exactly to reproduce given sounds, it is necessary, first, that these sounds should be analysed into vibrations, and these registered accurately in the manner described; and second, that their reproduction should be accomplished in the same period of time in which they were made, for evidently this element of time is an important factor in the quality and nature of the tones. A sound which is composed of a certain number of vibrations per second is an octave above a sound which registers only half that number of vibrations in the same period. Consequently if the cylinder be rotated at a given speed while registering certain tones, it is necessary that it should be turned at precisely that same speed while reproducing them, else the tones will be expressed in entirely different notes of the scale, higher or lower than the normal note as the cylinder is turned faster or slower. To attain this result there must be a way of driving the cylinder, while delivering the sound or speaking, at exactly the same rate as it ran while the sounds were being recorded, and this is perhaps best done by well-regulated clockwork. It should be understood that the machine illustrated is but an experimental form, and combines in itself two separate devices—the phonograph or recording apparatus, which produces the indented slip, and the receiving or talking contrivance which reads it. Thus in use the first machine would produce a slip, and this would for example be sent by mail elsewhere, together in all cases with information of the velocity of rotation of the cylinder. The recipient would then set the cylinder of his reading apparatus to rotate at precisely the same speed, and in this way he would hear the tones as they were uttered. Differences in velocity of rotation within moderate limits would by no means render the machine's talking indistinguishable, but it would have the curious effect of possibly converting the high voice of a child into the deep bass of a man, or *vice versâ*.

No matter how familiar a person may be with modern machinery and its wonderful performances, or how clear in his mind the principle underlying this strange device may be, it is impossible to listen to the mechanical speech without his experiencing the idea that his senses are deceiving him. We have heard other talking machines. The Faber apparatus, for example, is a large affair, as big as a parlour organ. It has a key-board, rubber larynx and lips, and an immense amount of ingenious mechanism which combines to produce something like articulation in a single monotonous organ-note. But here is a little affair of a few pieces of metal, set up roughly on an iron stand about a foot square, that talks in such a way, that, even if in its present imperfect form many words are not clearly distinguishable, there can be no doubt but that the inflections are those of nothing else than the human voice.

We have already pointed out the startling possibility of the voices of the dead being reheard through this device, and there is no doubt but that its capabilities are fully equal to other results just as astonishing. When it becomes possible, as it doubtless will, to magnify the sound, the voices of such singers as Parepa and Titiens will not die with them, but will remain as long as the metal in which they may be embodied will last. The witness in court will find his own testimony repeated by machine, confronting him on cross-examination—the testator will repeat his last will and testament into the machine so that it will be reproduced in a way that will leave no question as to his devising capacity or sanity. It is already possible by ingenious optical contrivances to throw stereoscopic photographs of people on screens in full view of an audience. Add the talking phonograph to counterfeit their voices, and it would be difficult to carry the illusion of real presence much further.

NOTES

MR. SORBY is busy perfecting his new method of studying minerals. Some very remarkable properties are still unexplained, and only the other day Mr. Sorby made a very great fresh advance in the subject.

IT is probable that Sheffield will be chosen for the meeting of the British Association in 1879. Nottingham was to have been the place of meeting, but a difficulty has arisen respecting the meeting there, and Sheffield has been unofficially written to. The matter is being warmly taken up by some of the principal townsmen, and there can be no doubt with a successful result.

A PHOTOLITHOGRAPHIC plate of the primary triangulation of the United States Geological and Geographical Survey of the Territories, carried on during the summer of 1877, by Mr. A. D. Wilson, chief topographer, has just been published by the United States Geological Survey, under the charge of Dr. F. V. Hayden. The area covered by these triangles extends from Fort Steele, in Wyoming Ty., westward to Ogden, in Utah Ty., a distance of about 260 miles, and north as far as the Grand Teton, near the Yellowstone National Park, including Freemont's Peak of the Wind River Range of the Rocky Mountains. The area embraces about 28,000 square miles, and within it, twenty-six primary stations were occupied, and their positions accurately computed. Besides these occupied stations, a large number of mountain peaks were located, which in the future will be occupied as points for the extension of the topographical work of the Survey. A base line was carefully measured near Rawlin's Springs, on the line of the Union Pacific Railroad, and from this initial base the work was extended north and west to the valley of Bear River, in Idaho Ty. Here a check base was measured, and the system expanded to the neighbouring mountain peaks to connect with the triangulation as brought forward from the first-mentioned base. Along the line of the Union Pacific Railroad the work was connected at six points with the triangulation system of Clarence King's 40th parallel survey. In addition to the importance of this sheet as the base work of the season's topographical work, it presents a most striking feature in the number of remarkably long sights which were taken from the summits of some of the most lofty mountains in the area explored. Many of these sights were over 100 miles in length, while some reach a distance of 135 miles. From Wind River Peak all the prominent points in the Big Horn Mountains were sighted, also the loftier peaks of the Uinta Mountains; the former are located 165 miles to the north-east, while the Uinta Mountains are situated about the same distance to the south-west. As these ranges were not in the scope of the season's work, they are not given on the chart.

THE *Annual Report of the Smithsonian Institution* for the year 1876, which has recently been published, is of general interest. The Institution continues to carry on its usual work with vigour and efficiency. Two important volumes of the Smithsonian Contributions to Knowledge, xx. and xxi., have been issued. The former on the Winds of the Globe, by Prof. Coffin, consisting of 781 quarto pages, is considered to be the most important contribution to knowledge which the Institution has given to the world. It presents a rich mine of information for the use of meteorologists, the physical geographer, and the mariner. Volume xxi. contains the following articles, viz. :—(1) Statements and Expositions of Certain Harmonies of the Solar System, by Prof. Alexander. (2) On the General Integral of Planetary Motion, by Prof. Newcomb. (3) The Haidah Indians by J. G. Swan. (4) Tables of Atmospheric Temperature in America. There has been published an important work on the Antiquities of Tennessee, by Dr. Joseph Jones, and another on the Archæological Collections of the U.S. National Museum; also a supplement to Prof. F. W. Clarke's work on the "Constants of Nature," consisting of tables of specific gravities, boiling and melting points, specific heats, &c. Large additions have during the year been made to the collections of the National Museum in charge of the Institution. In the Appendix to the Report there is a translation of the eulogy on Gay-Lussac by M. Arago; a biographical sketch of Dom Pedro II.; a translation of an important paper of Prof. Pilar on the Revolutions of the Earth's Crust, which will be read with interest by students of physical geography and geology. The subjects discussed in this article are the origin of the earth, central heat, the fluid envelope, organisms, ice, with a concise account of the theory of secular changes of climate resulting from changes in the eccentricity of the earth's orbit, antiquity of man, &c. Then follows a paper by Dr. D. Kirkwood on the Asteroids between Mars and Jupiter. But the article which will probably attract most attention is one by Mr. W. B. Taylor on Kinetic Theories of Gravitation. In this memoir, occupying about eighty pages, is given an interesting historical account of all the principal theories which have been advanced since the time of Newton to the present day to explain the nature of gravitation. Villemot, 1707; Bernouilli, 1734; Le Sage, 1750; Euler, 1760; Herapath, 1816; Guyot, 1832; Faraday, 1844; Seguin, 1848; Boucheporn, 1849; Lamè, 1852; Waterston, 1858; Challis, 1859; Glennie, 1861; Keller, 1863; Tait, 1864; Saigey, 1866; Croll, 1867; Leray, 1869; Boisbaudran, 1869; Guthrie, 1870; Crookes, 1873. These theories are all criticised with considerable acuteness. Mr. Taylor lays down six fundamental characteristics of gravity with which, he asserts, every theory must agree. But unfortunately it is in reference to the truth of some of Mr. Taylor's postulates that the greatest diversity of opinion exists. No kinetic theory of gravitation can fulfil his six conditions. Mr. Taylor seems to misapprehend some of the theories in important points, particularly those of Le Sage and Croll. The Appendix concludes with a number of interesting papers on Ethnology.

WE have already referred to Prof. A. Agassiz's intention of carrying out a series of researches in the Gulf of Mexico. With an assistant he is to be accommodated on board the United States Coast Survey steamer *Blake*, which has just sailed on a surveying cruise that will occupy this winter in the Gulf of Mexico. By a study of the animals dredged from the bottom of the Gulf, Prof. Agassiz will be enabled to make important comparisons with the fauna of the Atlantic, and especially as to growth, habits, migrations, and changes of living forms found in the waters near the British Islands and the Scandinavian Peninsula. The expedition is under the command of Lieutenant-Commander Charles D. Sigsbee, United States Navy, who has had several years experience on coast survey duty, and has been notably successful in deep-sea soundings.

NEW YORK will in all probability have a magnificent new Zoological Garden in Central Park before the end of another year. The Park Commissioners have little doubt that the amount of money, 300,000 dollars, necessary to make a commencement, will be subscribed without difficulty.

THE death is announced of Mr. Robert Hollond, a gentleman formerly well-known in connection with aeronautics.

THE Rev. Horace Waller writes to the *Times* that Col. Mason has been round Lake Albert Nyanza in a steamer, and corroborates the fact of its being a comparatively small land-locked lake. Col. Mason is in the service of the Khedive.

MR. STANLEY has arrived in Egypt, and is to spend a few days at Cairo. On New Year's Day he was to be entertained at a banquet by Sir George Elliot, M.P., to which the principal English and American visitors and residents were invited.

THE African Association presided over by the King of the Belgians has learnt by telegram that its travellers have safely reached Zanzibar.

AT a recent meeting of the Liverpool Historic Society, Mr. T. Glazebrook Rylands, F.S.A., read an important paper or "Ptolemy's Geography of the Coast from Caernarvon to Cumberland (including Cheshire and Lancashire). The paper was the preliminary result of extensive and long research, during which the author has found out that previous writers have examined Ptolemy's work carelessly or inadequately, and greatly misrepresented his *data*. It has, for example, been inferred for centuries that the Mersey was unknown to Ptolemy, and that the river known as Belisama was identical with the Ribble. This has led to further deductions of an erroneous character; as, for example, that there was a wide sheet of water making the mouths of the Mersey and the Dee undistinguishable, while two islands in it reared their heads, viz., Wallasey, separated by a branch of the tide through Wallasey Pool, and Wirral, separated by a strait almost coincident with the canal from Chester. Mr. Rylands believes—and there can be little doubt of the fact—that he has ascertained the ideas of Ptolemy and verified his measurements and mode of projection in a way wholly unknown to former inquirers. He has thus explained apparent anomalies and corrected misunderstandings of former writers. Commencing southwards at Caernarvonshire, he has verified the positions from beyond Pwllelli round by Caernarvon and Conway to the Dee; he has verified the positions of the Mersey and the Ribble, and all along the coast to St. Bee's Head, in Cumberland. In several instances where it was thought Ptolemy was in error, Mr. Rylands has shown he is correct, and it is a matter of surprise that where we should expect approximate truth only, the more rigid tests give more accurate results.

THE Bristol Naturalists' Society appears to be in a flourishing condition. It has recently added to its organisation a Physical and Chemical "Section," of which Dr. W. A. Tilden is secretary and Mr. P. J. Worsley president. The recent meetings of the Society have been more largely attended, and there appears to be a revived interest in physical science in the ancient city.

M. GAUTHIER VILLARS has just published a new edition of a highly interesting old book, "Lectures on Chemical Philosophy," delivered at the Collége de France in 1836 by M. Dumas. In this curious work all the prevalent ideas in chemistry were initiated. Not a single sentence has been altered, yet M. Dumas' lectures seem quite fresh and young, ready to be used by students in the highest schools. They were collected by M. Bineau, a gentleman who died twenty years ago, after having been a professor in the Lyons Faculty of Sciences.

THE sittings of the enlarged council of the Paris observatory came to an end last week. The resolutions come to, of which we have already given the substance, have been sent to M. Bardoux, the Minister for Public Instruction. The International Meteorological Service entered, on January 1, the twenty-first year of its existence, and will continue connected with the Paris Observatory, where it was established by M. Leverrier in 1857. The present head of the service is M. Front, a physicist connected with the service for many years, and trained by Leverrier himself. The first physicist-*adjoint* is M. Moureau, formerly a schoolmaster, whom Leverrier remarked for his zeal and assiduity in meteorological researches and observations. The great astronomer required no other scientific qualifications than intelligence and instruction obtained by personal exertion. He turned away many doctors in science and pupils of the highest schools who were wanting in the requirements he was anxious to secure, and sought to find them even in the humblest stations of life.

MR. JOHN FIELDING, of Todmorden, has just presented to the Aquarium at Westminster two specimens of *Proteus sanguineus*, obtained by his courier, C. F. Kohl, from the grotto of Adelsburg. They are said to be the first shown in England. A specimen of *Menobranchus lateralis* has been on view for some little time.

A MOST unfortunate series of disasters followed Mr. Carrington's endeavours to bring to London a collection of specimens of the Mediterranean fauna. Dr. Eisig, of the Naples Aquarium, offered him every facility, suggested localities, and placed some store-tanks at his service. A collection of fish zoophytes and corals was made, and seven tanks were fitted up on a cargo steamer to transport them to England. Shortly after starting a thunderstorm was encountered, the ship was struck by lightning, and the contents of two metal tanks were at once destroyed. Among other things a fine collection of mureen eels averaging 2 feet in length was thus lost. Rough weather for a day or two caused further deaths. After leaving Gibraltar the change of temperature proved excessively fatal, the bright-coloured animals suffering most. The heavy weather in the Channel broke some of the other tanks, so that but few animals reached England alive. Mr. Carrington, however, arranged for supplies with agents at Naples, Messina, Palermo, Valentia, Gibraltar, Tangiers, and Lisbon.

MR. B. RALPH, of Launceston, Cornwall, sends us a ripe strawberry which he gathered on December 29 from a hedge about 400 feet above sea-level. Pink strawberry blossoms, he states, are not uncommon. The thermometer stood at 50° in the shade. Bar. 29·2, with a west wind. Many of the commoner hedgeflowers linger on, such as lychnis and geranium. He also incloses some primroses, blossoming in an exposed situation outside his window.

TWO somewhat forcible shocks of earthquake were felt at Bologna on December 23, and a slight one at Alicante on the preceding day.

PROF. BARRETT, in a recent lecture on the telephone, gave a receipt for making a cheap one. Take a wooden tooth-powder box and make a hole about the size of a half-crown in the lid and the bottom. Take a disc of tinned iron, such as can be had from a preserved meat tin, and place it on the outside of the bottom of the box, and fix the cover on the other side of it. Then take a small bar-magnet, place on one end a small cotton or silk reel, and round the reel wind some iron wire, leaving the ends loose. Fix one end of the magnet near, as near as possible without touching, to the disc, and then one part of the telephone is complete. A similar arrangement is needed for the other end. The two are connected by the wire, and with this Prof. Barrett says he has been able to converse at a distance of about 100 yards.

M. BARDOUX, the new Minister of Public Instruction in France, has held a reception of the several heads of his department and *employés* of the central administration. He delivered a speech insisting upon the necessity for a Republican Government to educate the people, as a good system of public education is the strongest basis on which any Republic can be safely established. According to the *XIX. Siècle* M. Bardoux is not only preparing a Bill for establishing gratuitous elementary education, but also for organising a higher elementary education.

PROF. PFAUNDLER communicated in a recent session of the Vienna Academy the results of some experiments undertaken to decide the question as to the smallest absolute number of vibrations capable of producing a sound. By means of a siren with two openings for blowing, he finds that two isolated vibrations are capable of producing a tone which, by repetition, becomes audible.

THE Meteorological Society of Paris has elected as president M. Hervé Mangon, professor of Agriculture at the Conservatoire des Arts et Métiers.

THE Postal and Telegraph services are to be united in France, as they have been already in England, under a single direction. The first director of the complex organisation will be M. Cocheris, one of the staff of the *Temps* and a well-known writer on matters of political economy.

AT the last meeting, December 19, 1877, of the Russian Geographical Society, M. Mushketov made a very interesting communication on his last journey in the Tian Shan and to the Pamir, where he visited some places never before visited by European travellers. His researches enable us to correct many imperfections in the works of Gordon and Stoliczka, and to obtain many new and important data. A complete geological sketch of the Pamir highlands will soon be published by M. Mushketov. At the same meeting the secretary gave an account of a new expedition to Central Asia, which will start from St. Petersburg at the beginning of this year, under the leadership of Prof. A. E. Middendorff. The expedition has especially in view the study of the agricultural conditions of Turkistan, and the well-known traveller, zoologist, and practical agriculturist who is at the head of the expedition, will be supported in his work by MM. Smirnoff and Russow.

AT the meeting, December 15, of the St. Petersburg Society of Naturalists Prof. Kessler referred to the fishes brought this year by M. Polyakoff from the lakes Ala Kul and Balkhash. In addition to the seven species which were known before in the Central-Asian fauna he has discovered four new ones, one of which is the interesting fish described by the inhabitants as *Marenker* (its zoological description will soon appear), the flesh and caviare of which are poisonous.

PROF. BERTHELOT, of Paris, is probably the most prolific chemist of the day. We notice in the two last numbers of the *Annales de Chimie et de Physique*, the two last numbers of the *Comptes Rendus*, and the last *Bulletin de la Société Chimique de Paris*, thirty-two various articles under his name. Berthelot's researches are, however, confined to thermal and physical chemistry, and are not delayed by the analytical operations attendant on other branches of chemical investigation.

CAPT. J. O. LUNGINERS, of the Danish vessel *Luttefeld*, communicates to a Copenhagen paper an interesting account of a novel experience which occurred on December 10, 1876, while on a voyage to Valparaiso. The vessel was at this time in the neighbourhood of Terra del Fuego, about 140 miles from Magellan's Straits, when early in the morning it narrowly escaped collision with an island where no trace of land appeared on the charts. The vessel hove-to until daylight, when the captain proceeded with a boat's crew to the new island, which had gradually diminished in size since the first observation. Around the conical rocky mass the water was hissing, and although no smoke appeared, it was found to be too highly heated to permit of landing. The sinking continued slowly, until at eight o'clock the island was completely submerged, and an hour later the vessel passed over the spot where it had disappeared.

THE December Session of the Berlin Geographical Society was occupied by a long and interesting address from Dr. F. M. Hildebrandt, on the results of his late African explorations. We have already alluded in a late number to the unfortunate result of the expedition to the snow-clad mountains of equatorial Africa, when the explorer was compelled to return with Mount Kenia fairly in sight. The heroism of Dr. Hildebrandt in battling with danger and disease in manifold forms is only approached by the adroitness and ingenuity which characterised his dealings with the natives. Among the Hataitas he was regarded as a magician, and was forced to pronounce incantations on the unfruitful fields. For this purpose, at his request, specimens of all the plants and animals in the vicinity were gathered by the tribe, and after having served as a "fetish," were carefully packed away in the collections. On another occasion he was attacked by several hundred natives, who beat a hasty retreat, when the explorer advanced towards them armed with a photographic camera. Despite the constant succession of misfortunes accompanying Dr. Hildebrandt during his two years' explorations in Africa, he has succeeded in gathering together a large and valuable collection of anthropological and botanical specimens especially, from Cape Gardafui and the Comoro island Johanna. A number of new species and genera, particularly of aromatic plants, were discovered in the former locality.

THE additions to the Zoological Society's Gardens during the past week include two Lions (*Felis leo*) from Upper Nubia, presented by Mr. John Baird; a Green Monkey (*Cercopithecus callitrichus*) from West Africa, presented by Mr. J. Scott; a Bonnet Monkey (*Macacus radiatus*) from India, presented by Mr. J. H. Thompson; a Common Thicknee (*Œdicnemus crepitans*), European, presented by Mr. F. Möll; a Macaque Monkey (*Macacus cynomolgus*) from India, deposited; a Collared Fruit Bat (*Cynonycteris collaris*), a Geoffroy's Dove (*Peristera geoffroii*), bred in the Gardens.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

OXFORD.—An examination for a Radcliffe Travelling Fellowship will be held on February 11. Candidates should forward notice of their intention to offer themselves, on or before January 15, to Dr. Acland.

An examination will be held at Queen's College on April 30 to fill up an open scholarship in natural science, of the value of 90*l.*, tenable for five years.

LONDON.—We learn that in consequence of the success attending the course of Lectures on Physiology now being delivered at the Working Men's College, Great Ormond Street, by Mr. T. Dunman, the Council of that Institution have arranged for the delivery, by the same gentleman, of a supplementary advanced course of about sixteen lectures, the first of which will be delivered on Friday, January 18. The lectures will be accompanied by practical demonstrations. Mr. Dunman has been appointed to the lectureship in physiology at the Birkbeck Institution, recently vacated by Dr. Aveling.

MANCHESTER.—Mr. M. M. Pattison Muir, F.R.S.E., Assistant-Lecturer in Chemistry, and Demonstrator in the Laboratory of the Owens College, has been appointed Prælector in Chemistry at Gonville and Caius College, Cambridge.

BERLIN.—We notice in the report of a late session of the Prussian House of Deputies a very vigorous presentation, by Prof. Mommsen and Prof. Virchow, of the necessity for a new building for the royal library. This valuable collection of books—over 700,000 in number—is the largest in Germany, and increases so rapidly that the present quarters in the Imperial Palace are most inadequate. The Government shows an inclination to remedy the evil, and it is to be hoped that this chief store of mental pabulum for the Berlin student will soon be provided with a house of its own, and the much-needed catalogue of its treasures finally be published.

BUDAPESTH.—The committee intrusted with the preparations for the first centennial celebration of this university, have decided to invite all foreign universities to send representatives on the occasion. A work on the history of the university is being prepared by Prof. Theodor Pauler, the late Minister of Education.

HEIDELBERG.—In the recently-issued calendar of the University for the present semester we notice a serious falling off in the attendance, the present number of students (461) being 250 less than that for the past summer. This fact is chiefly due to the increasing custom of the German students to gather in the Universities of the great cities during the winter. The theological faculty includes 19 students, the medical, 79, the philosophical, 180, and the legal, 183. Heidelberg still possesses evidently its traditional attractions for English-speaking students, the catalogue containing the names of twenty-one Englishmen and twenty-six Americans, a large proportion of whom are studying under Bunsen. Of the sixty-seven other foreigners in attendance Switzerland contributes eighteen and Russia nineteen. The corps of professors numbers 105, of whom fifty-nine are in the philosophical faculty. Prof. Bluntschli, the leading authority on international law, is the pro-rector for the present year. We notice that Prof. Blum has been forced by advanced age to give up the chair of mineralogy. His connection with the University dates back to 1828, and under his direction the mineralogical department at Heidelberg has long been one of the favourite resorts of students from various countries, the museum ranking among the best in Europe. Prof. Blum's fame as a mineralogist rests chiefly on his thorough and exhaustive researches on pseudomorphs, the results of which are embodied in his work "Die Pseudomorphosen des Mineralreiches." A very complete and practical text-book of mineralogy, as well as the numerous smaller treatises on subdivisions of the science, which have appeared at intervals from his pen, are regarded as standard works.

STRASSBURG.—The grant of money for the new edifices of the university amounts to 10,500,000 marks (over 500,000*l*.). Of this sum 2¼ millions are contributed from the imperial funds, 5½ millions result from Alsace-Lorraine's share of the new imperial bank notes, and the remainder is contributed by the city, the district, and the two provinces. At present the university is attended by 627 students divided as follows among the faculties;—theological, 49, legal, 156, medical, 117, philosophical, 305. Despite the able corps of professors gathered together since the re-establishment of this historic university, the number of students shows a decrease of eighty as compared with 1876, a result due in a great measure to the coldness exhibited by the old French inhabitants towards the German students.

HOLLAND.—The Netherlands School Museum, at Amsterdam, was opened on December 24, 1877, in presence of Mr. Heemskerk (recently Prime Minister of Holland), and several authorities connected with the Educational Department. Mr. A. van Otterloo, for the committee, in his opening speech alluded to the valuable co-operation of England in the exhibition. The authorities afterwards inspected the museum, and expressed their high appreciation of the interesting collections of school appliances exhibited by the School Board for London and others.

ST. PETERSBURG.—A new High School for ladies is to be opened at St. Petersburg for the special purpose of preparing female teachers for women's colleges. The School is provided with the necessary money by a young lady, and it will be conducted by the professors of the St. Petersburg University.

Prof. Tarkhanoff, of the St. Petersburg Medical Academy, having assisted at the examinations in physiology and anatomy of the thirty-six ladies who have now finished their five years' course at the High School of Medicine at St. Petersburg, publishes a report on those examinations. The answers of the ladies, he says, were definite, clear, and often vivid. Deep and very accurate knowledge was shown in anatomy and histology, the examinations having been made according to the extensive programmes existing in ordinary universities. On the average the answers were quite as good as those of male students; but the answers of three or four ladies, by their completeness and brilliancy, produced a deep impression on the examiners, and greatly exceeded all the professor has ever witnessed either as a student or professor.

CHARKOW.—The annual calendar of this Russian university shows an attendance of 442 students. Over half of this number are freed entirely from the payment of lectures, while a third receive annual stipends varying from 180 to 340 roubles. The corps of instructors numbers sixty-four.

SOCIETIES AND ACADEMIES

LONDON

Royal Astronomical Society, December 14, 1877.—Dr. Huggins, F.R.S., in the chair.—A paper by Dr. Wolf, of Zurich, set forth that the sun-spot period varies from seven to sixteen years, eleven years being the average.—A paper by Mr. C. V. Boys described a new astronomical clock. Mr. Christie and Lord Lindsay criticised it.—A photograph of the sun was presented by M. Janssen. It is one of those taken daily at Meudon, measuring one foot in diameter. Dr. De la Rue said it was the finest example of celestial photography he had ever seen. It was not taken with an equatorial, but an instrument after the fashion of the Kew photoheliograph with a 5½-inch object-glass. The picture was not taken at the principal focus, but in that of a secondary magnifier, corrected independently of visual focus. He pointed out the tornadoes visible on the photograph, and spoke of the importance of a physical observatory to register the changes which occur on a tremendous scale every hour, sun-spots being phenomena of comparatively small importance. Capt. Abney spoke in corroboration, and said that M. Janssen at first thought these photographed tornadoes had an atmospheric origin. Mr. Christie said that similar phenomena had been found on the Greenwich photographs, and they had nothing to do with the collodion.—Mr. Glaisher read a paper on the law of force tending to any point whatever in the plane of motion in order that the orbit may always be a conic.—Mr. Lynn gave a description of Mr. Howlett's drawing of the solar spot of October 31 to November 3, being about 15″ diameter.—Lord Lindsay concluded the description of his spectroscope for nebulæ referred to last month.—Mr. Christie made some remarks and criticised it, and the meeting then adjourned.

Photographic Society, December 11, 1877.—Papers were read by Capt. Abney, R.E., F.R.S., on fog-producing emulsions and their rectification, and by H. B. Berkeley, on emulsions. Capt. Abney showed that the cure, or rather the elimination, of fog in emulsions (as also in dry plates) would be effected by the introduction of either bromide, iodine, or nitric acid into the emulsion. Nitric acid prevented the formation of any chemically-produced sub-bromide of silver, and reduced the fog to the state of bromide; where pure bromide is present, it seems almost impossible that there should be fog. If an emulsion plate is exposed to light, and afterwards partly dipped into copper bromide, then exposed in the camera and developed, the portion treated with the bromide will be found to be free from fog and perfectly clear.

PARIS

Academy of Sciences, December 17, 1877.—M. Peligot in the chair:—The following papers were read:—On the order of appearance of the first vessels in the shoots of some Leguminosæ (third part), by M. Trécul.—Note on the ring of Saturn, by M. Tisserand.—On intramolecular work, by M. Boileau.—On an essential improvement of the navigation lock with mixed oscillation, by M. De Caligny.—M. Cailletet was elected correspondent for the section of mineralogy, in room of the late M. d'Ommalius d'Alloy (obtaining thirty-three votes against nineteen for Mr. James Hales).—Production of crystallised sulphide, selenide, and telluride of silver, and of filiform silver, by M. Margottet. The former are obtained by passing vapours of sulphur, selenium, and tellurium, over silver (heated red) by means of a current of nitrogen.—The silver gets covered with the crystals. The crystallised sulphide is transformed into metallic and filiform silver by a current of dry hydrogen at 440 degrees. The corresponding reduction of the selenide and telluride takes place only at the highest temperatures the glass can bear.—Use of lacs of eosine and fluoresceine for preparation of decorative paintings without poison, by M. Turpin. A potassic or sodic solution of eosine, *e.g.*, treated by an acid, gives a precipitate of eosic acid insoluble in water; this washed till the water begins to take a rose-colour is insoluble in the hydrate of oxide of zinc, and so forms a very rich lac (eosinate of zinc) varying from rose to deep-red, according to the quantity of eosic acid used.—Vine districts attacked by phylloxera (1877), by M. Duclaux. It is noted with reference to L'Aude that the vineyards bordering on the sea (some kilometres in width) are preserved much longer than the others.—The natural enemies of the phylloxera in Germany, by M. Blankenhorn. The small extension of centres of phylloxera there is attributed to the fact that the stocks have been frequented, previous to the phylloxera infection, by natural enemies of the insect (which are specified).—On the intermediary integrals of the general equation with partial derivatives expressing that the problem of geodesic lines, considered as a problem of mechanics, supposes a rational integral with reference to components of the velocity of the moving body, by M. Lévy.—Calculation of the longitude or the hour of Paris at sea, by occultations of stars, by M. Baills.—On the conditions with limits in the problem of the elastic plates, by M. Boussinesq.—On the equation of Lamé, by M. Brioschi.—On apparatus for projection with polarised light, by M. Laurent. For polarisers the author uses Nicols made of two, three, or four pieces of spar, each piece with two faces cut parallel to each other and the cleavage; then he cements them together with a hard mastic, and operates the whole like a single piece of spar. The analyser used is a Nicol of 22 mm. diameter; it is placed at the principal focus of the projection lens.—Action of oxychloride of carbon on toluene in presence of chloride of ammonium, by MM. Ador and Crafts.—Action of stable anhydrous acids on stable anhydrous bases; explosion of the compound, by MM. Solvay and Lucion.—Anhydrous phosphoric acid and oxide of sodium may exist intimately mixed in fine powder without reacting at the ordinary temperature, but a rise of less than 100° causes instantaneous combination with remarkable violence. M. Lucion sees here no confirmation of the dualistic theory or argument against the unitarian.—On the sensibility of the pericardium in the normal and pathological states, by MM. Bochefontaine and Bouceret. The sound pericardium is sensible; the external face apparently more than the internal. The sensibility can be shown by mechanical excitations. The pericardium inflamed experimentally shows a lively sensibility, at least on the external face and inwards.—Maturation and diseases of the cheese of Cantal, by M. Duclaux. Enough water remains for development of ferments, and there are present lactic acid and albumen.—Observations on the zoological affinities of the genus Phodilus, by M. Milne-Edwards.—On the measurement of the dihedric angles of microscopical crystals, by M. Bertrand.—On the signification of various parts of the vegetable ovule, and on the origin of those of the seed (concluded), by M. Baillon.—Preparation of alcoholic chlorides and their application to the production of colouring matters, by MM. Monnet and Reverdin.

December 24, 1877.—M. Peligot in the chair.—The following papers were read:—On some applications of elliptic functions (continued), by M. Hermite.—On the rotatory power of metastyrolene, by M. Berthelot. Metastyrolene, derived in the cold state from active styrolene, has rotatory power (just as metaterebenthine shares the rotatory power of terebenthine). On the other hand, inactive styrolene, as prepared by the pyrogenic method, gives an inactive metastyrolene.—On Saturn's ring (continued), by M. Tisserand.—Observations on the Bahmie cotton plant, by M. Naudin. This plant, which is found in Egypt, and is very productive, is not, as supposed, a cross between cotton (*Gossypium*) and Gombo (or *Hibiscus esculentus*). It differs from the old race merely in aspect. It is still in process of improvement. The botanical species is the *Gossypium barbadense* of Linnæus and Parlatore, or Sea Island cotton. It requires much heat, and is recommended for Algeria, where the cotton industry has been declining.—Notions concerning intramolecular work (continued), by M. Boileau.—On M. Boiteau's recent communication regarding comparison of the phylloxera of the oak with that of the vine, by M. Balbiani.—On anthogenesic Homoptera, by M. Lichtenstein.—Progress of the phylloxera in the south-west of France, by M. Duclaux.—On the results obtained by use of sulphide of carbon for destruction of phylloxera, by M. Marion. Reiterated treatment with small quantities is recommended.—On the ventilation of the transport-ship *Annamite*, by M. Bertin. After three hours the volume of air evacuated under the sole action of heat from the chimneys was over 29,000 cubic metres, and might rise to 40,000. This movement of air would secure a renewal of air in the hospital about eight times in the hour.—The death of Ruhmkorff was referred to.—M. Dumas, *à propos* of MM. Cailletet and Pictet's almost simultaneous success in liquefaction of oxygen, read a passage from Lavoisier, showing he had anticipated such results.—On the condensation of oxygen and carbonic oxide, by M. Cailletet. His method was to expand the gases suddenly; when cooled to − 29°, and compressed to the extent of 300 atmospheres; a thick mist appears. This is had from oxygen, even at ordinary temperature, if it have had time to lose the heat acquired simply through compression. Hydrogen, under similar treatment, gave no such mist. Nitrogen was not experimented with.—Experiments by M. Pictet on liquefaction of oxygen, by M. de Lognes. The apparatus is described.—M. Dumas opened a sealed letter deposited by M. Cailletet on December 3, announcing his discovery. M. Pictet's results were announced on December 22. Several members expressed opinions on the subject.—New observations on the *rôle* of pressure on chemical phenomena, by M. Berthelot. He calls attention to the fact that the decomposition of chlorate of potash into oxygen and chloride of potassium an exothermic reaction, and not limited by its inverse, is not stopped by a pressure of 320 atmospheres.—On the employment of graphic methods in the prediction of occultations, by M. Tissot.—On the transformations of contact of systems of surfaces, by M. Fouret.—Experimental researches on magnetic rotatory polarisation; magnetic rotations of luminous rays of various wave-lengths, by M. Becquerel. He experimented specially with bichloride of titanium, interposing a spectroscope between the eye and the analyser in his former apparatus; and he notes some differences between the positive and negative magnetic rotations.—Ordinary and extraordinary indices of refraction of quartz for rays of different wave-lengths as far as the extreme violet, by M. Sarasin. The numerical results for lines of cadmium, sodium, zinc, and aluminium are tabulated.—Engraving on glass by electricity, by M. Planté. The surface of a plate of glass or crystal is covered with a concentrated solution of nitrate of potash (poured on it). A horizontal platinum wire, connected with one of the poles of a secondary battery of fifty to sixty elements, is placed in the liquid along the edges, then holding in the hand the other platinum electrode, covered, except at the end, with insulating matter, one touches the glass with it, and draws characters, &c., which remain distinctly engraven.—On acid acetates (continued), by M. Villiers.—On experiments showing that meningo-encephalitis of the convexity of the brain produces different symptoms, according to the points of this region that are affected, by MM. Bochefontaine and Viel.—On the conditions of development of Ligulæ, by M. Duchamp. He made two pigeons (which are pretty far removed from aquatic birds), swallow some ligulæ from a tench. After four and five days respectively they were killed, and each had in its intestine a living ligula with genital organs developed, and the matrices full of eggs (just as with the duck).—On a miocene alios in the neighbourhood of Rambouillet, by M. Meunier. This points to sudden cataclysm.—On thermal coloured rings by M. Decharme. He remarks on the difference in these on tinned and on zinked iron plates.

VIENNA

Imperial Academy of Sciences, November 8, 1877.—On the least absolute number of sound-impulses that are necessary to production of a tone, by M. Pfaundler.—On generalisation of known triangle propositions to any perfect *n* angles inscribed in a conic section, by M. Cantor.—On the perfect square in general, by the same.—On citramalic acid, by M. Morawski.—On accessory projections in the skull of leporides, by M. Mojsisovics.—On arbitrary and spasmodic movements, by M. Brücke.—On cork and corked tissues generally, by M. Höhnel.

THURSDAY, JANUARY 10, 1878

THE SALARIES OF THE OFFICERS IN THE BRITISH MUSEUM

THE inadequacy of the salaries of the officers of the British Museum has long been a standing grievance. It is manifestly impossible to give any valid reasons why the literary and scientific men of this great national establishment should not receive emoluments at least equal to those granted in the ordinary branches of the Civil Service. The obstinacy of the trustees in clinging to obsolete principles of priority, and in endeavouring to keep entirely in their own hands the right of nomination to all the more important posts, has, no doubt, been the main cause why the Treasury have until recently refused to do justice to a most meritorious and ill-treated branch of the public service. From the "Correspondence between the Trustees of the British Museum and the Treasury," which has lately been issued as a Parliamentary Paper, we are glad to find that in this instance, as on former occasions, the present Ministry has been induced to do justice where their predecessors in office have persistently ignored righteous claims. After a long correspondence, commenced in May, 1876, and extending over some fifteen months, it seems to have been finally settled that the salaries of the keepers of the various departments shall be raised to 750*l.* per annum after five years' service, instead of stopping at 600*l.*, the former limit, and that the salaries of the assistant-keepers shall rise to 600*l.* after five years' service, instead of being restricted to 450*l.* as heretofore. The assistants in the various departments will, in future, be divided into two classes, the first, or upper class, with salaries commencing at 250*l.* per annum, and rising by annual increments of 15*l.* to 450*l.*; those of the second, or lower class, commencing at 120*l.*, and rising by increments of 10*l.* to 240*l.* This will create a considerable general improvement in the position of these subordinates, of whom the junior assistants, as they are called, have hitherto commenced at 90*l.*, and the senior assistants have never risen beyond 400*l.* But the trustees have agreed to regard the new second class for the future as an "educational class," from which those persons who show special aptitude for the work of the different departments may be promoted to the first class, whilst those who have no extraordinary abilities must remain content with the maximum salary of the lower class. Another concession that the trustees have been compelled to make in order to obtain the above-mentioned advantages is a reduction in the number of the assistants of the upper class. The Treasury justly point out to the trustees that the scheme of having a first class of assistants double the number of that of the second class, is "inconsistent with all ordinary classification," and that the comparative numbers of the two classes "ought to be exactly reversed." This the trustees have, as it appears, somewhat unwillingly undertaken to effect, by a gradual reduction of the number of first-class assistants as vacancies occur, and by making all future appointments into the second class, except when "an opportunity occurs of securing the services of a person possessing very special qualifications."

A third point which the trustees "are prepared to reconsider" is the number of keeperships, now amounting to thirteen, and in order that the Treasury may have greater control in this matter, they have undertaken not to fill up any keepership which may hereafter become vacant, "without the previous concurrence of the Treasury." A still more important proposal made by the Treasury and "conceded by the trustees," is that the position of keeper should be considered as a "staff appointment, to which no officer within the Museum should have any right of succession by seniority." This "concession" will, we trust, do away with the practice of putting round men into square holes, in order to obtain for them an additional salary, which in former years has, we fear, been followed in some instances at the British Museum.

One remaining point, which has much exercised the well-known economy of the Secretary of the Treasury, we are pleased to see he has been obliged to give up. It was proposed that the keepers who occupy the residences attached to the British Museum ought to give up a certain portion of their salaries in lieu of rent. In reply to this ingenious suggestion, the trustees very justly urge that those keepers who reside on the premises have important duties to perform, in having to take in turn the general charge of the whole museum under the principal librarian, for which the accommodation of a residence is no more than a fair equivalent. This contention was ultimately allowed to prevail, and on the whole, we think, there is every reason to be grateful to the Government for the improvements effected by the new scheme in the position of the *employés* at the British Museum. Even in these hard times it cannot be said that a place of 750*l.* per annum with a good residence attached and a pension in future when work is no longer possible, is not such a prospect as may well attract some of the cleverest youths of the period who have a leaning towards literature or science to seek the place of "junior assistant" in the British Museum.

JULES VERNE

Hector Servadac, or the Career of a Comet.—From the Earth to the Moon.—Around the Moon.—Twenty Thousand Leagues under the Sea.—Around the World in Eighty Days.—The Fur Country.—A Winter amid the Ice, &c., &c. (London: Sampson Low and Co.)

THESE remarkable works, which we owe to the genius of Jules Verne, the first-named being that which has last appeared, are well deserving of notice at our hands, for in the author we have a science teacher of a new kind. He has forsaken the beaten track, *bien entendu*; but acknowledging in him a travelled Frenchman with a keen eye and vivid imagination—and no slight knowledge of the elements of science—we do not see how he could have more usefully employed his talents. He will at once forgive us for saying that when we compare his romances of the ordinary type, such as "Martin Paz," with those we have given above, we think that he, as well as his readers, is to be congratulated upon the new line he has opened out.

There have been many books before his time in which the interest has centred in some vast convulsion of nature, or in nature generally being put out of joint, but in these there has been no attempt made to reach the *vraisemblable;* indeed in most cases there has not been sufficient knowledge on the part of the author to connect his catastrophe either with any law or the breaking of one. But with Jules Verne for once grant the possibility of his chief incident, and all the surroundings are *secundem artem.* The time at which the projectile was to be shot out of the columbiad towards the moon was correctly fixed on true astronomical grounds, and the boy who follows its flight will have a more concrete idea of, and interest in, what gravity is and does, possibly, than if he were to read half-a-dozen text-books in the ordinary way. Once grant the submarine vessel and the use made of electricity, and the various scenes through which the strange ship passes are sketched by no 'prentice hand. To take the most extreme case, if it be possible to imagine one in such a connection—Algeria torn from the earth by a comet and started on an orbit of its own; the astronomical phenomena have been most carefully thought out, and children of larger growth will, if they choose, find much to learn as well as to amuse them. Indeed it is very rare that one finds our author tripping in such matters, although he does sometimes. One case that occurs to us is when, in the "Fur Country," he refers to the midnight sun touching the edges of the *western* horizon without dipping beneath it, and even this may be due to the translator, for we have not the original French edition to refer to.

Thus much premised let us see how, in "Hector Servadac," his last work, the author attempts, as part of his task, to inculcate scientific truths, remarking that his plot is carefully kept out of view till the end of the volume. He and his faithful servant are stunned by a crash, in which the earth groaned as if the whole framework of the globe were ruptured, while the sea and air became one, and both glowed in a radiance intenser than the effulgence of the northern lights. In the midst of a gigantic earthquake-wave he found the moon's disc becoming much larger than it was before, and a new blazing star appearing suddenly in the firmament. Strange to say watches, which are not stopped, mark two as the sun rises in the west! Next point. Their respiration became more forced and rapid, like that of a mountaineer when he has reached an altitude where the pressure of the circumambient air has become reduced; when they jump they fly. The horizon is contracted. There are more surprises: a strange body (the retreating earth) seems to contend in splendour with the sun; but the true condition of affairs has not revealed itself yet, for he is anxious to go and look for his fellow-men; *en attendant,* however, they must eat.

"'By jingo!' he exclaimed, 'this is a precious hot fire.' Servadac reflected. In a few minutes he said:—

"'It cannot be that the fire is hotter, the peculiarity must be in the water.'

"And, taking down a centigrade thermometer which he had hung upon the wall, he plunged it into the skillet. Instead of 100°, he found that the instrument registered only 66°.

"'Take my advice, Ben Zoof,' he said; 'leave your eggs in the saucepan a good quarter of an hour.'"

So much for the careful treatment of the first forty pages. At last the truth dawns upon Hector, and he finds others on the newly torn-off fragment, including even the very astronomer who predicted the comet. A new point in favour of the metric system is here introduced; for our astronomer, anxious to determine the density and mass of *Gallia,* as the fragment had now been named (this is more pardonable than Gallium), finds that not only the metre of the archives, but all other measures whatever had disappeared. He shows that—

10 5-franc pieces 37 mm. in diameter
10 2-franc ,, 27 mm. ,,
20 50-cent. ,, 18 mm. ,,

exactly make a metre.

A German Jew (M. Verne has his ideas of the different nationalities) is made to lend this sum at an enormous rate of interest, and the experiment proceeds.

"By the appointed time the engineer had finished his task, and with all due care had prepared a cubic decimetre of the material of the comet.

"'Now, gentlemen,' said the Prof. Rosette, 'we are in a position to complete our calculations; we can now arrive at Gallia's attraction, density, and mass.'

"Every one gave him their complete attention.

"'Before I proceed,' he resumed, 'I must recall to your minds Newton's general law, "that the attraction of two bodies is directly proportional to the product of their masses, and inversely proportional to the square of their distances."'

"'Yes, then,' continued the professor, 'keep—— "

"'Yes,' said Servadac; 'we remember that.'

"'Well, then,' continued the professor, 'keep it in mind for a few minutes now. Look here! In this bag are forty five-franc pieces—altogether they weigh exactly a kilogramme, by which I mean that if we were on the earth, and I were to hang the bag on the hook of the steel yard, the indicator on the dial would register one kilogramme; this is clear enough, I suppose?'

"As he spoke the professor designedly kept his eyes fixed upon Ben Zoof. He was avowedly following the example of Arago, who was accustomed always in lecturing to watch the countenance of the least intelligent of his audience, and when he felt he had made his meaning clear to him, be concluded that he must have succeeded with all the rest. In this case, however, it was technical ignorance, rather than any lack of intelligence, that justified the selection of the object of this special attention.

"Satisfied with his scrutiny of Ben Zoof's face, the professor went on:—

"'And now, gentlemen, we have to see what these coins weigh here upon Gallia.'

"He suspended the money bag to the hook; the needle oscillated, and stopped.

"'Read it off!' he said.

"The weight registered was one hundred and thirty-three grammes.

"'There, gentlemen, one hundred and thirty-three grammes! Less than one-seventh of a kilogramme! You see, consequently, that the force of gravity here on Gallia is not one-seventh of what it is upon the earth!'

"'Interesting!' cried Servadac, 'most interesting But let us go on and compute the mass.'

"'No, captain, the density first,' said Rosette.

"'Certainly,' said the lieutenant; 'for, as we already know the volume, we can determine the mass as soon as we have ascertained the density.'

"The professor took up the cube of rock.

"'You know what this is,' he went on to say. 'You know, gentlemen, that the block is a cube hewn from the substance of which everywhere, all throughout your

---

[1] "On this subject an amusing anecdote is related by the illustrious astronomer himself. One day, just after he had been alluding to this, as his usual habit, a young man entered the room, and feeling sure the lecturer knew him well, saluted him accordingly. 'I regret I have not the pleasure of your acquaintance,' said M. Arago. 'You surprise me,' replied the young student. 'Not only am I most regular in my attendance at your lectures, but you never take your eyes off me from the beginning to the end.'"

voyage of circumnavigation, you found Gallia to be composed—a substance to which your geological attainments did not suffice to assign a name.'

"The professor took the cube, and, on attaching it to the hook of the steel yard, found that its apparent weight was one kilogramme, and four hundred and thirty grammes.

"'Here it is, gentlemen; one kilogramme, four hundred and thirty grammes. Multiply by seven; the product is, as nearly as possible, ten kilogrammes. What, therefore, is our conclusion? Why, that the density of Gallia is just about double the density of the earth; which we know is only five kilogrammes to a cubic decimetre. Had it not been for this greater density, the attraction of Gallia would only have been one-fifteenth instead of one-seventh of the terrestrial attraction.'

"The professor could not refrain from exhibiting his gratification that, however inferior in volume, in density, at least, his comet had the advantage over the earth."

We have given this long extract to show the pleasant way in which, in this latest form of French light literature, amusement is combined with instruction. It would not be fair to the book to say more of the plot or of the *dénouement*.

We have dwelt especially upon Jules Verne's latest book, but equal praise must be given him for all those we have named. A boy, for instance, who had read how the frozen island in the "Fur Country" was kept together by Dr. Black's device, would at once understand the *rationale* of Pictet's and Cailletet's recent splendid work, to say nothing of the physical geography he would have gradually absorbed in following the strange adventures recounted in that volume.

We are glad to have such books to recommend for boys' and girls' reading. Many young people, we are sure, will be set thirsting for more solid information.

OUR BOOK SHELF

The Geometry of Compasses; or, Problems Resolved by the mere Description of Circles, and "the Use of Coloured Diagrams and Symbols." By Oliver Byrne. (London: Crosby Lockwood and Co., 1877.)

THIS is only our old friend, "La Geometria del Compasso di Lorenzo Mascheroni" (Paris, 1797), decked out in the manner we have indicated in the quoted portion of the title. The order of sequence has been departed from, but this is not a material point. The constructions are the same and the proofs the same with, we believe, one exception, in which case we give the preference for simplicity to Mr. Byrne.

There are twenty problems, which are in most cases given in duplicate, first construction and figure in colours, then proof and unadorned figure on the next two pages.

The merits and nature of Mascheroni's work are well known; hence the present work, for reasons given above, is good. But we cannot call this Mr. Byrne's book. Problem XX., which is the last, is an elegant construction for dividing the circumference into seven equal parts by plane geometry. But for this the compiler is indebted to an able mathematician, Dr. Matthew Collins. The book is very neatly and correctly got up, and for frontispiece has a hand with a pair of compasses transferring a given length.

Proceedings of the American Philosophical Society. Vol. xvi., No. 99. January to May, 1877.

PROF. COPE has several noteworthy papers in this part: one, on the Batrachia of the coal-measures of Ohio, describes the new genus, Ichthycanthus, and the new species of Leptophractus and Tuditanus. He also describes remains of a Dinosaurian from the trias of Utah; the humerus is one of the longest, and distally the most contracted known in the group. These remains are the first discovered fossils in the triassic beds of the Rocky Mountain regions. Another valuable paper is on the brain of Coryphodon. One of the longest contributions will be much esteemed by geologists, viz., Mr. Ashburner's measured section of the palæozoic rocks of Central Pennsylvania (Huntingdon County), a section extending vertically through 18,394 feet. A very valuable series of physiological experiments is recorded in a paper by F. L. Haynes, on the asserted antagonism between nicotin and strychnia. Philology is well represented by a paper on the Timucua language, by Mr. A. S. Gatschet; this language, formerly spoken in Florida, appears to be the oldest within the American Union of which writings of some extent are preserved.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.]

The Radiometer and its Lessons

WITH reference to the controversy between Mr. Stoney and Mr. Osborne Reynolds about the laws of the conduction of heat in gases, it seems desirable to call the latter gentleman's attention to the fact that neither Clausius' nor Clerk Maxwell's investigations, as published in the *Philosophical Magazine*, affect the controversy between them.

The latter, in his papers in the *Philosophical Magazine*, vol. xxxv., lays particular stress upon the fact that he supposes the motions of the molecules to be uniformly distributed in every direction. He says, however, on page 188: "When one gas is diffusing into another, *or when heat is being conducted through a gas*, the distribution of velocities will be different in the positive and negative directions instead of being symmetrical, as in the case we have considered." From this theory of the uniform distribution of velocities he deduces the formula (29), (31), and (32), as he numbers them, and to which he subsequently refers. On page 214 he gets an equation (143) which represents the transference of heat through the medium, and says: "The second term contains quantities of four dimensions in $\xi\ \eta\ \zeta$, *whose value will depend upon the distribution of velocity* among the molecules. *If* the distribution of velocity is that which we have proved to exist when the system has no external forces acting on it, and when it has arrived at its final state we shall have by equations (29), (31), (32) . . ." certain results from which he deduces his equation for the conduction of heat in gases.

When he says "has arrived at its final state" it is evident from his reference to the equations that he means the state of a gas in which neither diffusion nor conduction of heat nor currents of any kind are going on. It will thus be seen that his final result is only a first approximation and could not possibly be expected to hold within distances comparable with the mean length of the path of a molecule between two encounters.

Clausius in his paper as translated in the *Philosophical Magazine* for June, 1862, does suppose a distribution of velocity among the molecules of such a kind that the velocity and number of molecules moving in the positive and negative directions is different, but assumes the mean between them to be the same as the number moving in a direction normal to the direction of the transference of heat. This is evident from the fact that what he practically does is to assume that the number of molecules moving in a direction making an angle θ with the direction of transference of heat can be expressed by a formula of the form—

$$n = n_0 (1 + e \cos \theta),$$

for he neglects e^2 throughout his investigation. In this form it is evident that n_0 is the number when $\theta = \frac{\pi}{2}$ and is the mean of the values $n_1 = n_0 (1 + e)$ and $n_2 = n_0 (1 - e)$, which represent the numbers going towards and from the points of high temperature. From the fact that e^2 enters into the investigation at all it is evident that this is only an approximation to the true distribution. In accordance with this Mr. Stoney has shown conclusively that in a compressed Crookes's layer the number of molecules moving parallel to the direction of the transference of heat is greater than the number of those moving in any direction normal to it, so that the expression Clausius derived from his assumption cannot be considered as expressing the whole state of affairs.

It is remarkable that to this order the expression for the pressure on *any* plane is the same, but Clausius gives another term in his expression for the pressure on a plane normal to the direction of transference of heat to which he attaches, indeed, only an indefinite coefficient because it is of the order e^2, and he was purposely neglecting quantities of that order. He might have prophesied, however, from the existence of such a term that at distances comparable with e a force would be manifested such as Mr. Crookes has since discovered. Now this e is by definition a quantity of the order of the length of the mean path between successive encounters, and hence these terms, varying with e^2 would become of importance at distances comparable with the length of this mean path.

I believe, then, that I have shown that neither Clausius nor Clerk Maxwell have considered the case in dispute between Mr. Stoney and Mr. Osborne Reynolds, and that as far as their investigations bear upon it they tend very much to strengthen Mr. Stoney's case. I have also shown that Clausius was on the point of anticipating both Crookes's force and Mr. Stoney's explanation of it.

Trinity College, Dublin

Prof. Eimer on the Nervous System of Medusæ

SOME of your readers may remember that a few months ago I published in NATURE an abstract of a lecture which I had delivered at the Royal Institution on "The Evolution of Nerves." In this lecture I mainly treated of my recent researches on the nervous system of *Medusæ;* and stated, among other things, that I was the first to publish the observation concerning the paralysing effect of removing the margins of nectocalyces.[1] Within the last few days, however, I have received a communication from Prof. Eimer, of Tübingen, informing me that he has the right to claim priority as regards the publishing of this observation. I therefore send you this note in order that I may rectify the injustice which I previously did to Dr. Eimer in your columns.

The facts of the case are simply these: Dr. Eimer made his observation a few months later than I made mine; but, as he communicated his observation within a few weeks after he had made it to the *Physikalisch-medicinischen Gesellschaft zu Wurzburg*, his publication preceded mine. He has therefore the right to claim priority as regards this observation, and also as regards some further physiological experiments by which he followed it up—all of which I have been careful to detail in my Royal Society publications.

So much in justice to Dr. Eimer. In justice to myself I must now explain that, although, since the publication of my Croonian lecture in 1875, I have been aware that Dr. Eimer's work was independent of mine, it is only within the last few days I have learned from him that the publication of his work was prior to mine. The reason of the ambiguity on this head is explained in a newly-published memoir by Dr. Eimer, where it is stated that his previous memoir, having been published in the *Würzburg Verhandlungen* without its proper title-page, the initials "*d. J.*" ("this year"), which occur in the paper itself, refer, not to the date on the volume, but to the year preceding. My prolonged ignorance concerning Dr. Eimer's claim to priority, has, therefore, not been due to any fault on my part; and as in all my previous publications on this subject I have spoken of Dr. Eimer's work as subsequent to my own, I may here add that I think the fact of his having been so long in acquainting me with the true standing of the case, displays a laudable spirit of indifference on his part to the matter of mere priority.

GEORGE J. ROMANES

18, Cornwall Terrace, Regent's Park, N.W.

Mr. Crookes and Eva Fay

AFTER Mr. Cooper's courteous explanation which appeared in last week's NATURE (p. 183), I gladly exonerate him from blame.

To the publication of my letter in the *Banner of Light*, if Mr. Cooper thought it likely to do Eva Fay any good, I have no ground of complaint; but what I did, and do now, protest against, is the unauthorised publication of a lithographed *facsimile* of my letter in such a manner, and with such surroundings, as to leave no doubt that the intention was to throw discredit on my testimony as a trustworthy experimentalist.

I am glad to find that Mr. Cooper was no party to this breach of etiquette, and I willingly withdraw any expressions in my letter in NATURE (vol. xviii. p. 43) which may appear to reflect on him.

As a fitting climax to this controversy, may I request you to publish the subjoined letter from Eva Fay, which appeared in the *Banner of Light* for December 22 last?

London, January 7 WILLIAM CROOKES

"To the Editor of the *Banner of Light*, Boston, U.S.,
December 22

"I WISH to state a few facts in reference to an article in your paper of December 8, referring to myself, in a letter of Mr. Crookes on Dr. Carpenter's attack.

"First, it is untrue that Mr. Crookes gave me a letter speaking of the spiritualistic nature of my manifestations, and referring to Fellows of the Royal Society. The only letter, to my knowledge, that Mr. Crookes ever wrote regarding my mediumship (with the exception of the one written to Mr. Cooper) appeared in the London *Daily Telegraph*, and other journals, March 11, 1875.

"Second, in reply to Dr. Carpenter's statement that an offer was made by my managers in May, 1875, of an equivalent sum of money for me to 'expose the whole affair,' I will now say to Dr. Carpenter, as I did to my managers, *I have nothing to expose.*

"I am in receipt of a letter, dated November 18, 1877, asking me if I will fix a price to visit England under the title of an 'Exposée,' and show how I am supposed to have hoodwinked members of the Royal Society.

"My reply was as follows:—'As poor as I am, and as clever as I am supposed to be by Dr. Carpenter and others, I am obliged to decline your tempting proposition to replenish my exchequer by attempting impossibilities. I sincerely hope to be able to maintain myself and child in a more honourable occupation.' "ANNIE EVA FAY

"Akron, Ohio, December 10, 1877"

Volcanic Phenomena in Borneo

MR. WALLACE, in his work on the "Geographical Distribution of Animals," has the remark that no volcano, active *or extinct*, is known to exist within the area of the island of Borneo, notwithstanding that it is almost environed by a volcanic belt in full activity at a short distance. In fact, it seems to be generally understood that this vast island now represents, and has continued to represent for long past time, a perfectly quiescent area in so far as manifestations of subterranean energies are concerned. This view is doubtless strictly correct in regard to the existence of any volcanic vent which is now in action, or which has been so within the historical period; but it would be erroneous to deduce from it, as seems natural to do at first sight, the inference that the area is one of entire quiescence, or that it has been so free from volcanic action in any but the most recent times.

Speaking solely with reference to the north-west district, it may be observed that shocks of earthquake have been recorded more than once by credible witnesses during late years, viz., one in June, 1874, a second in June, 1876, and two more in July, 1876. These were recorded the first in Sadong, the three others in Saràwak. According to native testimony, slight shocks are by no means rare, and a severe one is particularly held in remembrance, which took place seventy or eighty years ago, and was accompanied by "a rain of ashes." Seismometrical observation would probably show that they are very frequent. These shocks seem to indicate that the island is directly affected by the proximity of the volcanic band above referred to.

As for the period of time preceding the historical epoch, there are not wanting signs that this part of Borneo was the theatre of a display of considerable volcanic energy, and it has yet to be shown that its date of activity was anterior to the deposition of the sandstone conglomerate formation of the country, which is, with the exception of very recent deposits, the most modern of the stratified rocks of this part of the island, it having been assigned—I know not with how much truth—to a later tertiary date on the evidence of the plant-remains found in the coal-seams which are associated with it.

---

[1] I first published this observation in a note to NATURE, which appeared in November, 1874.

Owing to the difficulty of determining questions of relative superposition in a country so densely clothed with vegetation, and to the insignificant depth of the sections, natural and artificial, which are accessible, coupled with the remarkably disturbed condition of large tracts of the sedimentary rocks—it is not possible to define at present the relations of the igneous to the sedimentary rocks of the district. Nevertheless, such evidence as I have myself been able to collect goes to support the hypothesis that the last outbreak of volcanic activity was posterior in date to all but the more modern deposits of shales, clays, river-gravels, &c., or, in other words, that it preceded more or less immediately, the last submergence of north-west Borneo—though separated from that submergence by a long interval, and possibly being the concomitant of an antecedent elevation of the land.

The traces of this outbreak remain in the existence of thermal springs, two at least of which occur in association with hills of trappean and basaltic rocks; the country in many parts is dotted with hills of basalt, columnar basalt, and felspathic porphyries, and in the intervening lowlands is seamed with dykes of porphyritic, hornblendic, and siliceous rocks; the sedimentary strata are greatly disturbed when the igneous rocks occur, being often upheaved at high angles and much plicated, and locally the sandstones and shales have been metamorphosed; whilst masses of a volcanic-conglomerate (?) are occasionally met with.

Philippine Islands, September 27 A. H. EVERETT

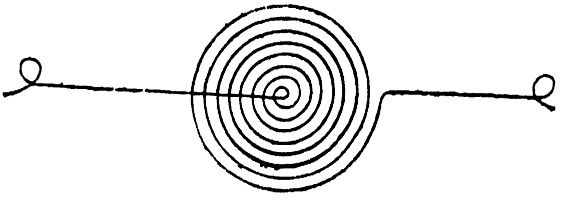
New Form of Telephone

HAVING had the pleasure of listening to Mr. Preece and Prof. Graham Bell explaining that most wonderful invention, the telephone, at the late meeting of the British Association in Plymouth, I endeavoured to obtain the instrument for my own use, and was ultimately successful.

It soon struck me that if the disc or diaphragm whose vibration causes the induced current in the coil of copper wire must be a magnetic substance, and not simply a conductor, then if I could succeed in getting an electro-magnet to vibrate in a similar manner it might be possible to get as powerful a sound.

With this object in view a coil of insulated copper wire was fastened to a card, as shown in Fig. 1.

Fig. 1.



The wire used was No. 28 cotton-covered, and it was sewed to the card with thread.

The iron disc was taken out of one of the telephones, and the coil-diaphragm put in its place through which a current was passed from a single Bunsen cell. On making connection with the other telephone, talking, singing, and whistling were heard distinctly at both.

Various coils have since been tried both with thicker and also thinner wire, but as yet the results have not been as good as when the iron disc is used.

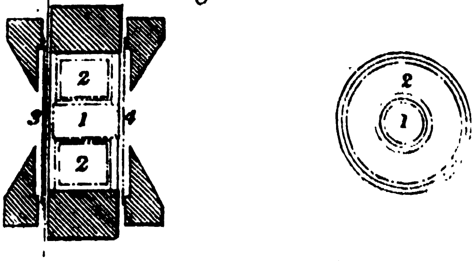
When two such coils are used, one superposed on the other, the loudness of the sound transmitted is increased to some extent. The same result is produced by adding another Bunsen cell. With a Daniell's cell the sound is very feeble. When a coil is placed in each telephone the result is rather unsatisfactory as yet.

It has also been noticed that a simple conductor as a coil of copper wire also transmits sound but very faintly.

A small apparatus (Fig. 2) has been made to show the effects above described. A piece of wood about three inches square and about one inch thick has a hole bored through it about two inches in diameter. A reel (2) containing about 250 yards of silk-covered copper wire is placed in the hole with a piece of soft iron about half an inch in diameter as axis (1).

A coil-diaphragm (3) is placed across one end of the hole at a very short distance from the soft iron core, and is covered by a mouth-piece. Across the other end of the hole at a similar distance from the core is placed a thin iron disc (4) which is also covered by a mouth-piece. On a current being passed through the coil-diaphragm this apparatus acts as a telephone, and messages can be sent from either side of it.

Fig. 2.



1. Iron core.
2. Coil of wire.
3. Coil diaphragm.
4. Iron disc.

The iron disc and core may be removed, and the coil-diaphragm alone acts in an exactly similar manner.

The above are the results of some experiments which have occupied my spare time lately, and not having seen anything similar published I forward them to you as they are rather interesting. The whole of the experiments have been conducted with the aid of my friend, Mr. G. B. Nicoll, who has also made many important suggestions. JAMES M. ROMANIS

Shooting Stars

THE number of shooting stars seen here during the last six months (July to December) is 2,259 in 168 hours of watching. This number includes 385 Perseids observed between August 3 and 16. Of the remaining 1,874 1,028 were seen during seventy-five hours in the mornings and 846 during ninety-three hours in the evenings. After making certain allowances for time spent in registering the paths (and omitting the Perseids), the horary numbers appear to have been as follows:—

16·4 A.M., 10·9 P.M., 13·4 A.M. and P.M.

From these figures I estimate that the aggregate number of shooting-stars as bright as, or brighter than, 5th mags., which entered the earth's atmosphere in this particular part of the world by night and day during the last six months, was about 236,700. The horary number has already been mentioned as 13·4 for one observer. Now a single pair of eyes certainly cannot command more than a fourth part of the visible sky, so that we must adopt 53·6 as the horary rate over the whole sky. From this we readily deduce the diurnal number as 1286·4, and the aggregate for the six months, 236,697·6 as above.

When it is further considered that the average height of ordinary shooting-stars is only about seventy miles, and that therefore observers at widely distant stations must each see a distinct set altogether, we are able to form some remote idea of the vast number that enter our atmosphere every day.

Bristol, December 26, 1877 W. F. DENNING

Gentiana asclepiadea and Bees

THIS gentian is very abundant on the mountain slopes round Engelberg, as visitors to that part of Switzerland well know. As I was botanising in the neighbourhood, in the autumn of this year, I observed that most of the flowers were pierced with a round hole at the base. Presently I saw a bee come to one of the pierced flowers, and thrust in its proboscis in search of honey. The flowers of this beautiful, sweet-smelling gentian are long and funnel-shaped, and very contracted at the base, and, as the bee that visited it was a "fair large" one, like Sir Torre's diamond, and not of the narrow hive-bee type, it could not possibly have effected its purpose by entering the flower in the usual way at the top, and had no doubt resorted to this method of extracting the honey. I only saw this one kind of bee visit the flowers, but I saw many of them at work, and all acted in the same way. One of them came to some of the flowers, which I had gathered, as I held them in my hand. I cannot say that I saw a single flower actually pierced by a bee; the day was warm, even for Engelberg, and the bees were very quick in their movements, which increased the difficulty of observation, but that the bees themselves were the agents, in making the holes, there can be no reason to doubt.

Highfield, Gainsborough, December 21 F. M. BURTON

Photography Foreshadowed

THE first prophetic allusion to the photographic art, the discovery of which was to take place eighteen centuries later, is perhaps found in the story of the miraculous occurrence told in the life of St. Veronica.

The second instance is about the year 1690; but intermediate instances may probably be found. I extract from the works of Fénelon[1] the following passage from an imaginary voyage in 1690:—"There was no painter in the country, but when anyone wished to have the portrait of a friend, a beautiful landscape, or a *tableau* which represented any other object, he put water in large basins of gold or silver; then placed this water opposite the object he wished to paint. Soon the water congealing became like a looking-glass, in which the image of that object remained ineffaceable; and it was a picture as faithful as the brightest mirrors." One could wish that the author had entered into detail as to the manner "of placing this water opposite the objects he wished to paint."

The third instance is about 1760, that is seventy years later, and seventy-nine years before 1839, the date of Daguerre's discovery. It is reported[2] by Ed. Fournier, who extracted from what he calls "un assez mauvais livre," written by a certain Tiphaigne de la Roche[3], the entire passage, extremely curious, but rather long. This passage contains many details. The "water" of Fénelon is replaced by "a material very subtle, very viscous, and very ready to dry and harden." "They" (certain "elementary spirits") coat with this material a piece of linen, and present it to the objects which they wish to paint," &c.

In the two last examples the pictures formed reproduce the images of the objects, with their natural colours and their forms, so that the objects are seen as if reflected in a mirror. The photographs of the present day are still very far from this ideal perfection, which, however, they will probably never cease to approach without ever being able to reach.

Rotterdam J. A. GROSHANS

Average Annual Temperature at Earth's Surface

HAVING lived for many years both in the southern and northern hemispheres, I have a very strong impression that if means were taken to ascertain, with more or less approximation, the average annual temperature at the earth's surface, by a combination of the daily averages of a sufficient number of places of observation, there would be found a very considerable difference in the yearly values of the said average annual temperatures. But whether, on inquiry, there should prove to be a decided difference or an absolute agreement between these averages, the fact in either case would surely be worth ascertaining, and could not fail to be instructive. It might be objected that it would be impossible to obtain the observations of the daily average temperature from such a number of observatories as would render the desired annual average for the whole earth of any value, but I think this objection overstates the difficulty. Suppose that the subject were taken up by some one of the meteorological authorities in Great Britain, it would not be difficult to obtain from existing daily records, a good average annual value for the temperature of the British Islands. Similarly, an average annual value could be obtained for the temperature, from the daily averages in the various colonies and dependencies of the British empire; and I take it to be certain, that the conductors of the various meteorological observatories all over the empire would cheerfully respond to an invitation to co-operate in such a work. In a similar scientific spirit it is to be hoped that the observatories of all civilised countries would be willing to exchange their observations, and an approximate result could thus be arrived at, possibly in two or three years. Certainly, it might be at first a rough approximation only, but it would be yearly becoming better with the rapid increase of meteorological observatories all over the world. And as it is not too much to hope that, sooner or later, the whole habitable earth will be civilised and covered with observatories, it is certain that the figures ultimately obtained to represent the average annual temperatures at the earth's surface would have the value of scientific approximations of considerable accuracy. If this be so, it cannot be too early to begin these statistics now.

Supposing that these annual averages should exhibit a difference in their yearly values, it is probable that these differences would vary in sympathy with the total sun-spot areas of the years to which they belonged. What could be done for temperature, could be done at the same time for other subjects of meteorological investigation, and it is impossible to anticipate at present what light these tabulated annual averages might be able to throw upon various problems of solar and terrestrial physics.

ON A MEANS FOR CONVERTING THE HEAT-MOTION POSSESSED BY MATTER AT NORMAL TEMPERATURE INTO WORK

IN a previous article[1] we considered how, by a simple mechanical means, diffusion renders it possible to derive work from matter at normal temperature. As the subject is an important one we propose to develop it somewhat further here.

2. The normal temperature of objects on the earth's surface represents a vast store of energy in the form of molecular motion. The sea (for example) at normal temperature possesses an amount of molecular energy which (by computation), if it were entirely utilised, would be competent to lift it to a height of upwards of seventy miles. The air and the crust of the earth itself possess comparable amounts of energy. It might therefore well be asked beforehand whether it is not possible to transfer some of this intense molecular motion to masses and utilise it. It may be observed that this intense store of energy is being continually dissipated in space in the form of waves (by radiation). The energy possessed by the molecules of matter, however, maintains (as is known) a constant normal value on account of the waves of heat received from the sun, whose mechanical value at the earth's surface (as represented by the results of Herschel and Pouillet) is normally equal to about one-horse power per square yard of surface. Here, therefore, we have a continual store of motion kept up in the molecules of matter on the earth's surface to be wasted in great part in imparting motion to the ether of space. It would certainly look, *à priori*, as if there ought to be some means of utilising this store of motion.

3. The second law of thermodynamics would (as is known) assume that this would not be practicable. This law was propounded simply as what was considered a legitimate inference from the observed behaviour of heat. But a great advance in the knowledge of the nature of heat has been made since that time, and it should be noticed that the law is (admittedly) by no means *theoretically* necessary or requisite to satisfy the principle of the conservation of energy. Indeed a conceivable case opposed to it has been pointed out by Prof. Maxwell, though one not capable of being practically carried out. It was my purpose in the last article to direct attention to a physical process opposed to the law and admitting of practical realisation, in the effects attendant on the diffusion of matter. At the time when this law was enunciated the character of the motion termed "heat" (as illustrated in the now accepted kinetic theory of gases) was unrecognised, and therefore the *mechanism* of the diffusion of gases was not understood. Under these conditions, therefore, it would not be much a point for surprise if increase of knowledge should show the law not to be generally applicable (or not to admit of that general application which is implied by the use of the term "*law*").

4. It may serve greatly to facilitate the following of this subject if we visualise the relations of heat and work more closely. Since "*heat*" is simply a *motion* of small portions of matter (termed "molecules"), and since the

---

[1] "On the Diffusion of Matter in Relation to the Second Law of Thermodynamics," see NATURE, vol. xvii. p. 31.

transference of this motion to visible masses is called "*work*," so therefore the conversion of heat into work is no more than the transference of motion from small to large portions of matter, *i.e.*, the transference of motion between portions of matter of *different* dimensions. *The mechanical equivalent of heat* therefore simply represents *the equivalence in energy between the motions of portions of matter of different dimensions* (molecules and visible masses). To deny, therefore, that the heat possessed by matter at normal temperature could be converted into work would be to assume that by a certain difference in dimensions the conditions are such that motion can no longer be transferred from the smaller portions of matter to the larger. This would evidently, *à priori*, be by no means a necessary assumption; indeed it would appear, perhaps, rather strange that by no device could such a thing be done.

5. At the first sight one difficulty in the way of utilising this motion that surrounds us on all sides is that the larger scale portions of matter (visible masses) are immersed among the smaller scale portions of matter (molecules) which surround the visible masses on all sides (as the molecules of the surrounding air, &c.), so that a perfect equilibrium of motion exists on all sides; so that it becomes impossible to transfer the motion to the larger scale mass in the one direction or in the other, and we cannot lay hold of each moving molecule individually, on account of its minute size.

6. It is an observed fact (and demonstrated theoretically) that portions of matter in motion among themselves tend to acquire the *same* energy of motion (called "temperature" in the case of molecules). In accordance with well-known facts, whenever the energy of this system of small moving portions of matter is greater in one part than in another, *i.e.*, whenever the equilibrium of energy is upset, then we can transfer some of the energy to larger scale masses (convert heat into work). Is there, however, no other means of converting heat into work but through *inequality of energy?* It was pointed out in the last article that *inequality of velocity* (by the mechanism of diffusion) will serve the same purpose. The portions of matter (molecules) which by equal temperature possess equal energy, possess, when their *masses* are unequal, unequal velocities. This inequality of *velocity* can be utilised for work as well as inequality of *energy*.

7. Since size is only *relative*, or there is nothing absolute in size, it will be quite legitimate to suppose molecules magnified up to a larger scale so as to be visible, and we do this as in dealing with the *mechanism* of a process, it is almost impossible to visualise or conceive clearly the results without this condition, and it is our object, on account of its practical bearing, to exhibit the process involved in a clear light. Suppose, therefore, the molecules of two diverse gases (oxygen and hydrogen) to be magnified up to visible dimensions, and as we are not concerned with the shape or form of the molecules, we may simply represent the molecules of the two gases by a number of spheres, those representing hydrogen possessing each one-sixteenth of the mass of those representing oxygen, and also possessing a normal velocity four times as great. This is known to be the fact in the case of the two gases when at the same temperature. We will further suppose the spheres inclosed in the two separate halves of a cylinder with a piston between them. The spheres may either be supposed perfectly elastic or their motion kept up artificially in some way; just as in the case of a gas the motion of its molecules is kept up by the molecular vibrations of the sides of the cylinder.

8. The spheres of the two sets possess *equal* energies of motion, the one set making up in mass for what they want in velocity. The colliding spheres in each compartment will arrange themselves (according to a known principle) so that the number of spheres in unit of volume of each set is the same, and therefore the pressure exerted by their impacts on opposite sides of the piston will produce perfect equilibrium, so that the piston remains immovable. Now the question is, supposing that (as in the case of molecules) we cannot lay hold of each of these spheres separately, is there any means of utilising the *inequality* of velocity for the performance of work? [This is the question we have to make in the case of two gases at the same temperature, whose molecules we cannot grasp, and which possess *unequal* velocities.] If we could by any device get a number of the spheres from one compartment into the other without changing their velocities in the act, then the pressure would evidently rise in one compartment, and we should thus obtain a capacity for work without the performance of work. It is evident that this could be done by making several perforations in the piston, about the size of the spheres themselves, so that the spheres, in impinging against the piston would sometimes happen to encounter the void space of a hole, and thus pass through with unchanged velocity into the opposite compartment. If the spheres of the two sets were moving with *equal* velocities, it is evident that as many on an average would pass through one way as the other, and there would therefore be no disturbance of the equilibrium of pressure, and consequently no work to be derived. But from the fact that the spheres are moving with *unequal* velocities, a different result will ensue. It will be evident that the number of spheres passing through the hole will be proportional to the number of times they strike against the piston, for the chances that a sphere will encounter a hole will be proportional to the number of its impacts against the piston, *i.e.* to the *velocity* of the sphere. So the velocity of the spheres in one compartment being four times that in the other, four times as many lighter spheres pass through one way, as heavier spheres pass through the other. The number of spheres in one compartment will therefore rapidly augment, and thus the *pressure* against the piston will rise, and the piston will be finally driven towards the opposite end of the cylinder, and in this act *energy* will be transferred from the spheres in the one compartment to those in the other; or part of the energy could be transferred to an outside mechanism in a self-acting manner if desired, by simply connecting the piston to the mechanism.

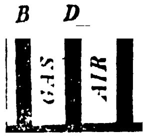
9. Now if precisely the same thing can be done in the case of two gases, it is evident that here the energy being *heat*, we have in the result attendant on the motion of the piston, the transference of heat from one portion of gas to another at normal temperature, *i.e.* the transference of heat in a self-acting manner from a *colder to a hotter portion of matter;* and if desired, a conversion of a part of the heat of the gas (at normal temperature) into *work* by cooling it down below the temperature of the coldest of surrounding objects.

10. In the case of a gas it is clear that we cannot make perforations analogous to the above sufficiently small to suit molecules, but to attack molecules we must have recourse to *molecular* mechanism, or to attempt to handle them like the spheres we must have recourse to mechanism on a suitable scale. We have such a mechanism in a porous diaphragm (such as of pipeclay or plumbago) which represents a piston with *molecular* perforations. Such a diaphragm, if fitted as a piston into a cylinder will exhibit, with the molecules of two separate gases possessing different molecular velocities (such as molecules of oxygen and hydrogen), precisely the same phenomena as those exhibited, simply on a magnified scale in the case of the spheres; or the above description applies word for word. We have by the motion of the porous piston *the conversion of the heat-motion of the gas at normal temperature into work*, the transference of heat automatically from the *colder* portion of gas to the warmer. The second law of thermodynamics only holds when the molecules brought into contact happen to be of the *same*

kind, or, more accurately speaking, of the *same mass*. This latter case is evidently exceptional, and if a case be exceptional the term "*law*" becomes no longer applicable to it.

11. The rates of diffusion of hydrogen and oxygen across the porous diaphragm are known to be as four to one, *i.e.* as the *molecular velocities*. The above illustration of the spheres may serve to exhibit the *physical basis* or cause of this fact in a clear light. The mere statement that the rates of diffusion are inversely as the square roots of the molecular weights of the gases, evidently throws no light on the cause or *physical basis* of the action, which is always the main thing to realise in physical science. The fact that diffusion is in the above ratio to the molecular weight, evidently only happens to be true because the molecular *velocity* is in that same ratio to the molecular weight, otherwise molecular weight has nothing whatever to do with the rate of diffusion. So it will be equally apparent, from the above illustration, that the rate of diffusion of a gas through a porous diaphragm has nothing whatever to do with the *pressure* of the gas, but depends, *cæteris paribus*, on the number of molecules of the gas in unit volume. An increase of the number of molecules in unit volume (by adding to the number of impacts of the molecules against the vessel) increases the pressure, and this is why diffusion *appears* to be dependent on pressure, though evidently *physically* it has nothing to do with it. This serves to explain how, provided the molecular velocities of the gases are considerably diverse, such enormous differences of pressure can take place by diffusion through a porous diaphragm, the pressure having no power whatever to adjust itself through the diaphragm; for the passage of a molecule through the diaphragm simply depends whether, in its normal motion, it happens to encounter a pore or not. The above illustration may also serve to show that the velocity of propagation of any impulse ("wave") by a system of bodies in free collision can only be dependent on the *normal velocity of the bodies*, just as a system of couriers interchanging motion among themselves convey a message at their own rate. So the molecules of a gas interchanging motion among themselves convey an impulse at their own rate, and thus the velocity of sound in a gas can be solely dependent on, and proportional to, *the velocity of the molecules of the gas*, and on nothing else. This must evidently be true on the basis of the kinetic theory, and this theory being now accepted, it would be not unreasonable to expect that in so fundamental a matter as the propagation of sound, an explanation of it on the basis of this theory would be looked to, for a *statical* theory of the propagation of sound appears scarcely to harmonise with the *dynamical* theory of gases. We have alluded to this fact as briefly as possible, having the illustration of the spheres at hand. There may be a liability to lose sight of facts like the above unless due care be taken to realise molecular phenomena by picturing them on a larger scale. The velocity of sound in hydrogen is four times greater than in oxygen, solely because the velocity of the molecules of hydrogen is four times greater than the velocity of the molecules of oxygen—nothing conceivably to do with the molecular weight of the gas, excepting in so far as a less molecular weight determines a higher molecular *velocity*.[1] The rate of propagation of the wave is affected by temperature in so far as the *velocity* of the molecules of the gas (in whose motion the *heat* of the gas consists) is affected by temperature.

12. As an illustration of a simple form of apparatus adapted for converting normal temperature heat into work, and admitting of continuous actuation, the following rough sketch may serve:—Let the annexed diagram represent a cylinder containing three pistons, B, D, C, the central one, D, of which is furnished with any porous diaphragm (such as of plumbago, or porous earthenware). Let any light gas (hydrogen being the most effective) be supposed introduced into one-half of the cylinder, some heavier gas (or air) filling the other half. All three pistons are supposed (first) fixed. Then, as is known, diffusion commences through the porous diaphragm, everything remaining necessarily at normal temperature so long as the pistons are fixed and no work is done. The rapidly moving molecules of the light gas pass in greater numbers through the pores of the diaphragm than those of the heavy gas (or air), so that the pressure rises in the compartment originally filled with air. As soon as the pressure has attained a maximum, the central piston is automatically released, and is thus driven by the excess of pressure towards the opposite end of the cylinder, the portion of gas which does the work being chilled and the heat transferred in the form of work to the outside machinery with which the central piston is connected. A certain part of the heat goes to the portion of gas *towards* which the piston is driven, heat thus passing from a colder to a hotter body (for as soon as the portion of gas commences to be chilled, it is already the colder). Simultaneously with the stroke of the central piston, a convenient automatic arrangement connected with the machinery oscillates the two end pistons inwards and outwards, expelling in the inward stroke (through convenient openings) the diffused mixture of gas and air, and by the outward stroke drawing in a fresh supply. Of course the valves suitable for this are not given, as it is only our purpose to sketch the *principle* of such an apparatus as a scientific point, and having no regard to any question of commercial value or not. Clearly the power derived would depend on the specific gravity of the gas used, and would be proportional (*cæteris paribus*) to the area of the piston. Coal gas would give a less power than hydrogen. A diffused mixture of gas and air is necessary for gas engines, the mixture being exploded in them. It is clear that it would be possible, by means of an apparatus of the above character, to derive power in the act of mixing the gas and air previous to exploding the mixture. The gaseous mixture, after passing through the apparatus, could be stored in some reservoir or receptacle, so as to recover (before combustion in the gas engine) from surrounding objects the heat which it lost by conversion into work in the diffusion engine. By this procedure it may be observed that the heat converted into work is derived from *the normal store of heat possessed by surrounding objects*, and their store is finally made good by the sun, which latter may therefore be regarded as the ultimate source of the energy derived.



13. In view of the numerous porous structures existing in the animal and vegetable world (*porosity* being a distinguishing characteristic of animal and vegetable organisms), also taking into consideration the prevalence of gases of different molecular weights, notably oxygen and carbonic acid (which are known to be intimately connected with animal and vegetable processes); the conclusion would seem warranted, and even necessary, that work on the above principle must take place widely in nature, and thus part of the store of energy accumulated in materials on the earth's surface by the sun, is made to fulfil a useful end, instead of being dissipated uselessly in space.

S. TOLVER PRESTON

---

[1] It is evident that though the velocity of the wave is proportional to the velocity of the molecules, the *absolute* velocity of the wave must be to a certain fixed degree less than that of the molecules; for the molecules in their normal motions are moving more or less *obliquely* to the path of the wave. This I have pointed out in a paper, published in the *Philosophical Magazine* for June, 1877, where the true mathematical relation for the velocity has been determined by Prof. Maxwell, and is there given.

ARARAT[1]

IN the childhood of mankind the dwellers in Western Asia cherished the story of a great flood which drowned all their race save one man and his family. They told the tale from father to son, how the flood rose till it covered their highest hills, and how the ark in which their ancestor had saved himself, his family, and a motley crowd of animals floated on the waters until, when these abated, it came to rest on the first emerging summit of the land. They chose as the scene of this new starting-point for humanity the loftiest peak of which they had knowledge—a vast snowy cone shooting far into the blue air above, and shrouding itself every day in cloud and storm. No one had ever climbed to its mysterious summit since the ark rested there. But generation after generation looked up to it with awe and veneration from the plains of Armenia. The story spread far away into other lands. It became part of the religious teaching of nearly a half of mankind. No mountain is so familiar, all the world over, as that from which Noah is famed to have descended to re-people the earth. The first conception which, as children, most of us have formed of a mountain, arose out of this story of Ararat.

Apart from its legendary associations and the mystery arising from its reputed inaccessibility, there must be something strangely fascinating about Ararat. Men who have seen much of mountains in many countries speak of it as the noblest mass among them all. The summit of its snowy cone (17,000 feet) greatly exceeds any European peak in elevation, and sweeps up from the level plain of the Araxes (2,500 feet) as from a sheet of water. It looks as if it might well claim to be linked with the oldest of human traditions.

So impressive a mountain, so long associated with man's faith and history, would have been appropriately placed among the most ancient landscapes of the earth's surface. Some scenes suggest only the changes of yesterday; others set us thinking of the earliest condition of our world. We naturally look for a kind of consonance between the venerable antiquity of the associations which gather round Ararat and the primeval character of the mountain itself. But geology delights in contrasts, and nowhere could so impressive a contrast be found between the remoteness of the tradition and the comparative youth of the mountain on which it lingers. Here we find no colossal pyramid of granite with outer folds of more ancient rocks such as have been built up and carved into the oldest mountain-chains. In reality it is but a mountain of yesterday, possibly not so old as the advent of man upon the earth, certainly much younger than many plants and animals now living.

Great and Lesser Ararat from the North-east.

To a student of the evolution of the earth's surface-features there is something profoundly suggestive in the long line of depressions and ridges which separates Europe from Africa, and stretches eastward through the heart of Asia. On the one hand, he sees the basins of the Mediterranean, Black, Dead, Caspian, and Aral Seas; on the other he notes how, in a general sense, parallel with these deep troughs, run massive mountain ridges, including the great axis of the Old World. He finds, on closer research, that while most of these ridges have received their latest upheavals at a recent geological date, they yet for the greater part belong originally to earlier periods of disturbance, some of them, indeed, bearing witness to many successive uplifts during a vast section of geological time. Yet further examination will bring before him evidence that along some of these lines of earth-folding, volcanic action has of old been abundant; and that the present Mediterranean volcanoes are but the lingering remnants of the chain of actively burning mountains which ran through Asia Minor and crowned the peaks of the Caucasus. And he will discover that just as there have been successive uplifts of the same axis or mountain-chain, so have there been widely-separated outbursts of volcanic activity during a long course of ages from the same focus of discharge.

It is in relation to this remarkable history that Mount Ararat acquires its main geological interest. Thanks chiefly to the veteran Abich a good deal is now known of the geology of the Caucasian and Transcaucasian ridges. He has shown how a nucleus of Devonian and carboniferous limestone rocks appears even under the mass of Ararat, and has drawn the inference from his wanderings in that region, that in the beginning of the Upper Carboniferous Limestone period a great continental upheaval took place during which the Armenian region received its first outlines. The land thus raised he believes to have remained above water until, in the course of the Cretaceous period, it so far sank as to become an island, and continued in this condition even into Pliocene times, when the whole of that region became involved in another vast continental upheaval to which the final modelling of the Armenian highlands was due. These great terrestrial movements were accompanied by the outbreak of volcanic action. Abich regards the diabase, diorite, and porphyry rocks as having been abundantly erupted during the Jurassic period and to have played an important part in the formation of the mountain masses, especially in the Lower Caucasus. To late Tertiary times, however, belong the trachytic and doleritic lavas which have been poured forth on so colossal a scale as to form such mountains as Elbruz, Kasbek, Ala Göz, and the two Ararats.

---

[1] Transcaucasia and Ararat. By James Bryce. (London: Macmillan and Co., 1877.)

In Mr. Bryce's recently published volume (to which attention has already been drawn in NATURE) we have a record of the latest and probably the most daring ascent of Mount Ararat. Though not a professed geologist he has had a geological training, and has seen much of many lands, alike in the Old World and in the New. It was not to make out any obscure point in the structure of Ararat that he bent his steps towards that little known mountain. But he had climbed many a peak in Europe, and he no doubt longed to set foot upon the high places of another continent. So he made a pilgrimage to the heights of Armenia, with no thought, however, of writing a book about his journey. The volume he has just published has been partly wrung from him by the importunity of friends, who reasonably supposed that the world might be as much interested as they in knowing more about Ararat. In its charmingly fresh and graphic pages one gets such a living picture of the mountain as cannot be gained from any of the geological memoirs. From long experience of mountain climbing his eyes are so keen and so trained, while his pen is so facile and vivid that we can mount with him as he goes warily over each lava-current, rubbish-cone, and snow slope. We feel the sharp thin air of the mountain as it blows through his narrative. We join in his quiet chuckle as he halts at a solitary piece of wood far up on the cone and irreverently detaches a fragment for the inspection of those who cannot personally discover whether the true ark still rests on the top of Ararat. And we can sympathise with his awe as he stood among the clouds alone on the summit of the mysterious mountain. It is not for any new scientific facts so much as for the vivid sketch of the general aspect of the huge volcanic mass that his book has an interest to geologists.

A vignette of Ararat forms the frontispiece of the volume, which is here reproduced. In the middle distance is shown the alluvial plain of the Araxes. Below the snowy cone and icy cliffs of the Greater Ararat a deep cleft or recess appears with huge cliffs somewhat like the Val del Bove of Etna, and no doubt due to some of the volcanic explosions of the mountain. On the skyline of this slope, towards the base of the larger cone some of the late cinder-cones and craters appear. Some of these are still so fresh and perfect that they look as i they had been active only the other day and might blaze forth again to-morrow. The graceful outline of the Lesser Ararat rises on the left.

ARCH. GEIKIE

AGE OF THE SUN IN RELATION TO EVOLUTION

ONE of the most formidable objections to the theory of evolution is the enormous length of time which it demands. On this point Prof. Haeckel, one of the highest authorities on the subject, in his "History of Creation," has the following:—"Darwin's theory, as well that of Lyell, renders the assumption of immense periods absolutely necessary. . . . If the theory of development be true at all there must certainly have elapsed immense periods, utterly inconceivable to us, during which the gradual historical development of the animal and vegeable proceeded by the slow transformation of species . . . the periods during which species originated by gradual ransmutation, must not be calculated by single centuries, but by hundreds and by millions of centuries. Every process of development is the more intelligible the longer it is assumed to last."

There are few evolutionists, I presume, who will dispute the accuracy of these statements; but the question arises, does physical science permit the assumption of such enormous periods? We shall now consider the way in which Prof. Haeckel endeavours to answer this question and to meet the objections urged against the enormous lapse of time assumed for evolution.

"I beg leave to remark," he says, "that we have not a single rational ground for conceiving the time requisite to be limited in any way. . . . It is absolutely impossible to see what can in any way limit us in assuming long periods of time. . . . From a strictly philosophical point of view it makes no difference whether we hypothetically assume for this process ten millions or ten thousand millions of years. . . . In the same way as the distances between the different planetary systems are not calculated by miles but by Sirius-distances, each of which comprises millions of miles, so the organic history of the earth must not be calculated by thousands of years, but by palæontological or geological periods, each of which comprises many thousands of years, and perhaps millions or milliards of thousands of years."

Statements more utterly opposed to the present state of modern science on this subject could hardly well be made. Not only have physicists fixed a limit to the extent of time available to the evolutionist, but they have fixed it within very narrow boundaries.

Every one will admit that the organic history of our globe must have been limited by the age of the sun's heat. The extent of time that the evolutionist is allowed to assume depends, therefore, on the answer to the question, What is the age of the sun's heat? And this again depends on the ulterior question, From what source has he derived his energy? The sun is losing heat at the enormous rate of 7,000 horse-power on every square foot of surface. And were it composed of coal its combustion would not maintain the present rate of radiation for 5,000 years. Combustion, therefore, cannot be the origin of the heat.

Gravitation is now almost universally appealed to as the only conceivable source from which the sun could have obtained his energy. The contraction theory advocated by Helmholtz is the one generally accepted, but the total amount of work performed by gravitation in the condensation of the sun from a nebulous mass to its present size could only have afforded twenty million years' heat at the present rate of radiation. On the assumption that the sun's density increases towards the centre, a few additional million years' heat might be obtained. But on every conceivable supposition gravitation could not have afforded more than twenty or thirty million years' heat.

Prof. Haeckel may make any assumption he chooses about the age of the sun, but he must not do so in regard to the age of the sun's heat. One who believes it *inconceivable* that matter can either be created or annihilated may be allowed to maintain that the sun existed from all eternity, but he cannot be permitted to assume that our luminary has been losing heat from all eternity.

If 20,000,000 or 30,000,000 years do not suffice for the evolution theory, then either that or the gravitation theory of the origin of the sun's heat will have to be abandoned.

In a former paper (*Quarterly Journal of Science* for

July, 18,7) I have proved from geological evidence that the antiquity of our habitable globe must be at least three times greater than it could possibly be had the sun derived its heat simply from the condensation of its mass. This proves that the gravitation theory of the origin of the sun's heat is as irreconcilable with geological facts as it is, according to Haeckel, with those of evolution, and that there must have been some other source, in addition, at least, to gravity, from which the sun derived his store energy.

That other source is not so inconceivable as has been assumed, for it is quite conceivable that the nebulous mass from which the sun was formed by condensation might have been possessed of an original store of heat previous to condensation. And this excessive temperature may be the reason why the mass existed in a nebulous or rarefied condition. Now if the mass were originally in a heated condition then in condensing it would have to part not merely with the heat of condensation, but also with the heat it originally possessed.

The question then arises—By what means could the nebulous mass have become incandescent? From what source could the heat have been obtained? The dynamical theory of heat affords, as was shown several years ago (*Phil. Mag.* for May, 1868), an easy answer to this question. The answer is that the energy in the form of heat possessed by the mass may have been derived from *motion in space.* Two bodies, each one-half the mass of the sun, moving directly towards each other with a velocity of 476 miles per second, would, by their concussion, generate in a *single moment* 50,000,000 years' heat. For two bodies of that mass, moving with a velocity of 476 miles per second, would possess 4,149 × 10^{38} foot-pounds of kinetic energy, and this, converted into heat by the stoppage of their motion, would give out an amount of heat which would cover the present rate of the sun's radiation for a period of 50,000,000 years.

There is nothing very extraordinary in the velocity which we have found would be required to generate the 50,000,000 years' heat in the case of the two supposed bodies. A comet having an orbit extending to the path of the planet Neptune, approaching so near the sun as to almost graze his surface in passing, would have a velocity of about 390 miles per second, which is within eighty-six miles of that required.

It must be borne in mind, however, that the 476 miles per second is the velocity at the moment of collision. But more than one-half of this velocity, or 274 miles per second, would be derived from their mutual attraction as they approached each other. We have consequently to assume an original or projected velocity of only 202 miles per second. If the original velocity was 678 per second, this, with the 274 derived from gravity, would generate an amount of heat which would suffice for 200,000,000 years. And if we assume the original velocity to have been 1,700 miles per second, an amount of heat would be generated in a single moment which would suffice for no less than 800,000,000 years.

It will be asked, Where did the two bodies get their motion? It may as well, however, be asked, Where did they get their existence? It is just as easy to conceive that they always existed in motion as that they always existed at rest. In fact, this is the only way in which energy could remain in a body without dissipation into space. Under other forms a certain amount of it is constantly being transformed into heat which never can be retransformed back again, but is dissipated into space as radiant heat. But a body moving in void stellar space will retain its energy in the form of motion undiminished and untransformed for ever, unless a collision takes place.

The theory that the sun's heat was originally derived from motion in space is, therefore, for this reason, also more in harmony with evolution than the gravitation theory, because it explains how the enormous amount of energy which is being dissipated into stellar space may have existed in the matter composing the sun untransformed during bygone ages. Or in fact for as far back as the matter itself existed.

In conclusion there are only two sources conceivable from which the sun could have derived his heat. The one is *gravitation*, the other *motion in space*. The former could have afforded only about 20,000,000 or 30,000,000 years' heat, but there is in reality no absolute limit to the amount which may have been derived from the latter source, for the amount generated would depend on the velocity of motion. And when we take into consideration the magnitude of the stellar universe, the difference between a motion of 202 miles per second, and one of 1,700 miles to a great extent disappears, and the one velocity becomes about as probable as the other.

It may be urged as an objection to the theory that we have no experience of bodies moving in space with such enormous velocities as the above. This objection, for the following reason, is of no weight.

No body moving with a velocity exceeding 400 miles per second could remain a member of our solar system; and beyond our system there is nothing visible but the stars and nebulæ. These stars, however, are suns like our own, and visible because, like the sun, they have lost their motion—the lost motion being the origin of their light and heat. Bodies moving in stellar space with these enormous velocities can have neither light nor heat, and, of course, must be invisible to us. They must first lose their motion before the kinetic energy in the form of motion can be transformed into light and heat, so as to constitute visible suns.

JAMES CROLL

ON THE FORMATION OF HAILSTONES, RAINDROPS, AND SNOWFLAKES[1]

THE author commences by recapitulating some of the leading points in a paper which he read before the same Society on October 31, 1876, "On the Manner in which Raindrops and Hailstones are Formed." In this paper, which was published in NATURE (vol. xvi. p. 163), he had shown that the aggregation of the small cloud particles into raindrops or hailstones is *sufficiently accounted* for by the fact that the larger *particles descend faster* than the others, and consequently *overtake those immediately* beneath them, and, combining *with these, form* still larger particles, which move *with greater velocity,* and more quickly overtaking the *particles in front of* them, add to their size at an increasing rate. He also showed that the shape and structure of ordinary hailstones was exactly such as would result from this manner of formation. For he had observed that the shape of hailstones was not as it at first sight appeared, that of more or less imperfect spheres, but that of more or less imperfect cones or pyramids with rounded bases, the conical surfaces being striated, the striæ radiating from the vertex; the texture being that of an aggregation of a number of small ice particles without crystalline form, being packed more closely together toward the base or rounded face of the stone. In this paper the author had reverted to the possibility of making *artificial hailstones* by blowing a stream of frozen fog against a small object, making, as it were, the cloud to rise up and meet the stone, instead of the stone falling through the cloud.

He had not, however, then overcome the difficulty of obtaining such a stream of frozen fog, but gave two sketches of plaster stones, which, as far as their shape and the striated appearance of their surface were concerned, closely resembled hailstones, and which plaster stones had been obtained by blowing some finely-divided plaster of Paris against small splinters of wood by means of a jet of steam.

---

[1] Abstract of paper by Prof. Osborne Reynolds, F.R.S., read at the Manchester Literary and Philosophical Society.

In the discussion which followed the reading of that paper Dr. Crompton suggested the ether spray, such as is used in surgery, as a means of obtaining a frozen fog, and Prof. Reynolds explains how after various attempts he had succeeded in combining a spray of ether and water so as to form artificial stones. He then proceeds as follows:—

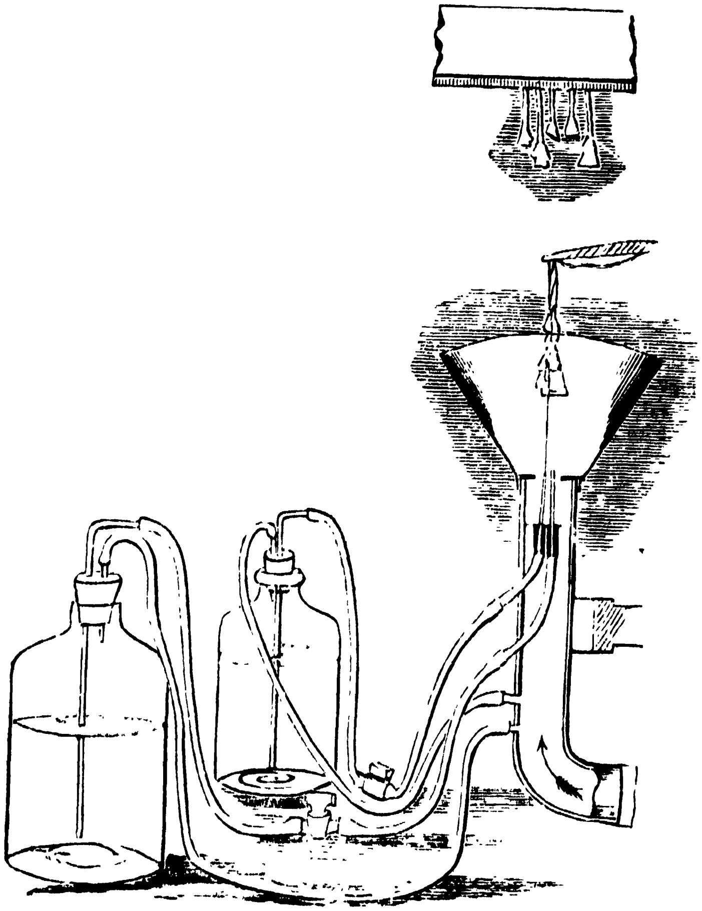


Fig. 1.

The apparatus is shown in Fig. 1. It consists of a brass tube half an inch in diameter, one end of which is connected with bellows capable of maintaining a constant pressure of about 18 inches of water, on the other end of the tube is a cap over the end of which is a flat plate or diaphragm having a central opening $\frac{1}{8}$ of an inch in diameter which forms the aperture for the blast. Entering through the sides of the main brass tube are two small brass tubes which reach to within $\frac{1}{2}$ an inch of the plate and into the ends of which are sealed fine glass capillary tubes, the glass being very thin; these protrude just through the middle of the aperture, the one about $\frac{1}{10}$ of an inch and the other $\frac{1}{32}$. Through these tubes the water and ether are separately introduced into the blast to form the spray, and it is mainly on the adjustment of these tubes that the efficiency of the apparatus depends. It is essential that the ether tube should be slightly the longest, otherwise the ends become stopped with ice, and I find it better that the ether tube should be somewhat larger than the water tube. The bore of the tubes must be very small, but this is not sufficient, for unless the glass is very thin the spray will not be finely divided. Both the ether and water are forced through the tubes from bottles by connecting the interiors of these bottles with the bellows, and the quantities of ether and water are regulated either by raising and lowering the bottles or by means of the cocks in the pipes.

The tube is fixed in an ordinary retort-stand, so that the blast is vertical. If then a small splinter of wood is held pointing downwards into the spray, a lump of ice forms on the end of the splinter, and this lump has all the appearance of the hailstones. It is quite white and opaque, it is conical in form and has a rounded base and striated surface.

In this way I have formed stones from half to three-quarters of an inch in diameter. When, however, the stones are growing large it is necessary to move this splinter so as to expose in succession all parts of the face of the stone to the more direct action of the spray.

When using this apparatus in a warm room I have found it best to fix a pad of blotting paper over the jet at a height of 10 or 12 inches. The surface of this pad is cooled by the spray and prevents radiation from the ceiling, which otherwise tends to melt the top of the stone. For a similar reason I have found it well to surround the blast with a wide cylinder or inverted cone of paper, which keeps off radiation without interfering with the action of the jet.

By sticking several pieces of wood into the pad, pointing downwards, a number of stones may be made at once.

In Fig. 2 a medium-sized stone as well as one of the largest stones are shown attached to the splinters of wood. The surface of the cone, where continuous, is truly conical, or rather pyramidal, but this surface is broken, as it were by steps, and a very marked fact is that all the continuous surfaces have the same vertex, and hence the different conical surfaces to which they belong, have not the same vertical angle, the surface being exactly such as would be acquired by the fragments of a sphere so constituted that the fracture tended to follow radial lines.

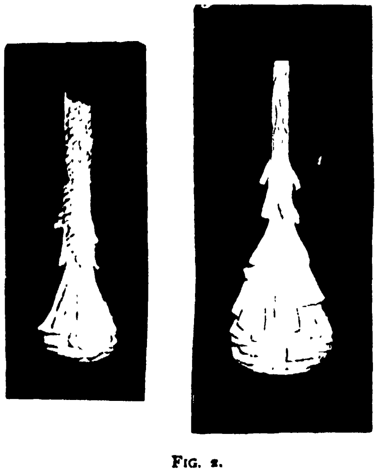

Fig. 2.

Owing to the radiation of the surfaces from a common vertex and the steps which occur between the vertex and the base, the angle of the conical surface of the stone is greater near the vertex than near the base. Thus the smaller stones appear less elongated than those which are larger.

The fact that in the sketches of actual stones, which I gave in my last paper, I showed the steps as less pronounced and the angles larger than they are in the artificial stones, is probably owing in some measure to my having formed my ideas from the observation of favourable specimens chosen from amongst those which fell. The larger angles were probably also, in part, owing to the smaller size of the actual hailstones, which were not much more than one-fourth of an inch across. But I think that it is important to notice that the somewhat imperfect way in which the outside layers in the surface of the artificial stones are continued, may be owing to the narrowness of the jet of air which, on striking the stone, tends to diverge laterally rather than to flow upwards past the sides of the stone, as it would do if the jet were broader, or as the air must do when the stone is falling through it.

The rate at which stones can be formed depends on the amount of water which can be introduced into the spray, the larger stones taking from one to two minutes. At first sight this may seem to be somewhat slow, but the following estimate tends to show that the artificial are probably formed quicker than the actual stones.

The speed of the jet of air at the point at which the stones are formed is nearly equal to that at which the larger stones would fall through the air. This is shown by the fact that if a large stone becomes accidentally detached from its splinter of wood it rather falls than rises, but when this happens with smaller stones they are driven up by the force of the blast.

I find that the speed of the blast varies from 150 to 200 feet per second, *i.e.*, from one-and-a-half to two miles a minute. The larger stones, therefore, traverse from one to four miles of frozen spray. So that if we imagine a cloud as dense as the spray it would have to be from one to four miles thick in order that the stones might, in falling through it, attain the size of the artificial stones; and considering that the stones would only gradually acquire a speed equal to that of the blast, the time occupied in falling through the cloud would in all probability be very considerable, at least from five to ten minutes after the stone had acquired a sensible size.

As regards the proportion which the density of spray bears to that of a cloud, a comparison may be made from the fact that when working in saturated air at a temperature of 60° or 70° F., the condensation of vapour supplied sufficient ice to form the spray; and since it is probable that the dense summer clouds, from which hail is formed, result from the cooling of air from temperatures nearly, if not quite, equal to this, there is probably no great difference in the density of the clouds and the spray.

I have not yet had an opportunity of examining the texture of these stones under the microscope, but to all appearance they consist of an aggregation of small spherical particles of ice; and it seems worthy of notice that while nothing like a snow crystal ever appears to be produced in the ether spray, the moment the blast is stopped the end of the ether tube becomes covered with ice, which often assumes the form of snow crystals.

This appears to indicate the character of the difference between those conditions which result in snow and those which result in hail.

When the cloud-particles are formed at or above the temperature of 32° and then freeze, owing to cooling by expansion or otherwise, the particles as they freeze retain their spherical form. This is what happens in the spray.

On the other hand, when saturated air at a temperature below 32° is still further cooled, the deposition of the vapour will be upon ice, and will take the form of snow crystals.

The aggregation of the snow crystals into flakes is, as I pointed out in my previous paper, accounted for by the larger crystals overtaking the smaller crystals in their descent, and the still more rapid descent of the flakes as they increase in size.

As regards the formation of rain-drops, I have nothing to add to what was contained in my last paper. The same explanation obviously applies to both hail and rain, and any doubt which may have been left by the less direct arguments in my former paper will, I venture to think, have been removed by the verification of my predictions in the production of artificial hailstones so closely resembling in all particulars those formed by nature. And, in conclusion, I would thank Dr. Crompton for the suggestion of the means by which I have been able to produce these stones.

OUR ASTRONOMICAL COLUMN

THE SOUTH POLAR SPOT OF MARS.—Prof. Asaph Hall has instituted a series of measures of the position of the south polar spot of Mars, with the Washington refractor during the late favourable opposition of the planet, having been led thereto by the great discordances in the positions of the spot, as determined so far. He adopts Oudeman's node and inclination of the equator of Mars, which, for the epoch taken, viz., 1877, September, 17·0, G.M.T. give N = 47° 56′, I = 39° 14′, and the angle of position of the south pole 162° 6′, and assumes the time of rotation of the planet 24h. 37m. 22·73s., as found by Mr. Proctor. The observations were made with a power of 400, and on thirty-two nights, from August 10 to October 24, during the whole of which period the spot was always seen with great distinctness, and little change in its appearance noted except what might be accounted for by change of distance. From thirty-four equations of condition treated on the method of least squares, Prof. Hall finds for the angle of position of the south pole of Mars at the above-mentioned epoch 166° 22′, for the radius of the small circle described by the spot 5° 11′, and for the angle of position of the spot at the epoch, with respect to the rotation-axis of the planet, 311° 24′. The various determinations of the south polar distance of this spot are as follow:—

	°	′		°	′
Herschel, 1783 ...	8	8	Linsser, 1862	20	0
Bessel, 1830	8	6	Kaiser, 1862	4	16
Madler, 1837	12	0	Hall, 1877	5	11
Secchi, 1857	17	42			

On several of the finer nights, when the markings on the edge of the spot were very distinct, it appeared as "a depression in the surface of the planet."

PROF. NEWCOMB'S LUNAR RESEARCHES.—It is understood that if no unforeseen delay occurs in the printing, Part I. of "Researches on the Motion of the Moon," upon which Prof. Newcomb has been engaged for six years past, will be ready for publication in the course of next month. It is devoted to the discussion of eclipses and occultations previous to 1750. An abstract appeared in *Silliman's Journal* for November last.

THE CORDOBA OBSERVATORY.—In an address delivered on November 4, on the occasion of receiving from the Governor of the province of Cordoba the premiums awarded at the Centennial Exhibition in Philadelphia to the Argentine National Observatory and to himself for Lunar and Stellar Photographs, Dr. B. A. Gould gave a brief outline of the successive applications of photography to astronomical purposes since Mr. Bond's experiments with the 15-inch refractor of Harvard Observatory in 1850, with more particular reference to work executed at Cordoba of late in this direction. Dr. Gould expresses himself satisfied with the results obtained at the Argentine Observatory; the photographs of the moon at full and in the last quarter he thinks may be favourably compared with any obtained elsewhere which he had seen. He refers to "the very beautiful picture of the moon" made with the 4-feet reflector at Melbourne, which was also exhibited at Philadelphia, and adds, he is not sure, if he had seen this elegant photograph before placing his own on exhibition, he would have ventured to compete. Dr. Gould remarks that much of the credit of the stellar photographs is due to the pure air of Cordoba, which is incredibly transparent on the not very numerous occasions when the sky is really clear. The impressions on glass exhibited were of six different clusters, the plate of the cluster X Carinæ containing two images each of 185 stars, and that of η Argus containing 180, and many of the stars as faint as the ninth magnitude. Measurable photographs of not less than eighty-four celestial objects have been secured, of which nineteen are double stars and the remainder clusters. The planets Jupiter, Mars, and Saturn, have also been photographed "with sufficient distinctness to show clearly the details of light and colour on the surfaces of the two former, and the existence of the ring in the latter," but the images have not been sufficiently sharp to allow of successful photographic enlargement.

VARIABLE STARS.—Herr Palisa in *Ast. Nach.*, No. 2,174, mentions his having remarked a new variable star, the position of which for 1877·0 is in R.A. 16h. 4m. 35s., N.P.D. 109° 48′·9. It does not occur on Chacornac's chart No. 49; it was 10m. on May 26, 1876, and on July 31 and August 3 of last year, whereas on May 17, 1877, no trace of it was perceptible. The period is therefore no doubt comparatively short.

The star L. 36606 = B.A.C. 6641 appears to vary from 6·5m. to 9m. On October 17, 1852, Argelander estimated it of the former magnitude, Lalande and Piazzi call it an eighth, while about midsummer, 1851, it was little, if anything, over the ninth magnitude.

L. 26211 is probably variable from 6m. to 8m., and L. 27307 from 7m. to 9m., and it is not unlikely that further observations will place b^2 Geminorum on the list of variables; it has been rated at a fifth magnitude and as low as 8½.

THE MINOR PLANET EVA.—A planet of the eleventh magnitude, observed by Herr Palisa at Pola on December 29, is mentioned in the *Bulletin International* of January 3, as possibly No. 180, but according to a communication from Herr Knorre, of Berlin, as probably identical with No. 164, detected by M. Paul Henry at Paris on July 12, 1876, which received the name *Eva*. The observations of 1876 extended over an interval of little more than a fortnight, and the elements which have been calculated by Mr. Winslow Upton and M. Bossert are therefore liable to uncertainty, but if we adopt Mr. Upton's orbit and compute for the time of the Pola observation, the place is found to be about a degree only from that observed, and it is therefore probable that No. 180 has yet to be discovered.

THOMAS VERNON WOLLASTON

THE very limited band of scientific English entomologists has just suffered a great loss by the sudden death, on the 4th instant, at his residence, 1, Barnepark Terrace, Teignmouth, of Thomas Vernon Wollaston—a name dear to science, and of which he well upheld the reputation. Accurate, elaborate, and precise *ad punctum*, and naturally of a minutely critical habit, he nevertheless persistently acted upon a broad conception of the science to which he was devoted; and taking advantage of the periodical banishments to a warmer climate imposed upon him in early manhood by pulmonary weakness, set himself the task of thoroughly investigating the coleopterous fauna of the Madeiras, Salvages, and Cape de Verdes, and finally of St. Helena. His philosophical deductions from the vast mass of well-sifted evidence obtained (chiefly by his own bodily toil, though he was always in a more or less debilitated state of health) referring to these isolated groups, may be summed up as corroborating the former existence of that submerged Atlantis whereon geologists differ. From the exhaustive care with which his material was obtained, it seems highly unlikely that his premises were insufficient; and his discussion of the subject so far resembles Mr. Darwin's method that it supplies the objections likely to be raised, and itself practically exhausts criticism by minuteness of observation.

To students of British entomology, Mr. Wollaston is best known by his early papers in the *Zoologist* and Stainton's *Entomologists' Annual and Weekly Intelligencer*, and by his revision of *Atomaria* in *Trans. Ent. Soc.*, 1877 His first scientific contribution was in the *Zoologist*, vol. i. (1843), on *Coleoptera* at Launceston, when a student at Jesus College, Cambridge (where, with the late J. F. Dawson and Hamlet Clark, he imbibed from Dr. Babington a taste for natural science), and his last, a paper in the *Annals and Magazine of Natural History*, on a weevil destructive to the banana in Madeira, was received from him by the writer almost simultaneously with the news of his death. He published many descriptive and analytical papers, almost exclusively on *Coleoptera*, in the above-named publications, the *Journal of Entomology* and the *Entomologists' Monthly Magazine*; but his *magnum opus* is the well-known "Insecta Maderensia," published in 1854, the results of his sojourns in Madeira, to which he first went in 1847. This, from its amount of novelty and classical treatment, at once established his reputation.

His collection, increased by another visit in 1855, having been purchased by the trustees of the British Museum, he prepared a more complete account, which was published as a museum "Catalogue" in 1857. Subsequent visits in 1858 and 1859 resulted in a description of the coleopterous fauna of the Canaries, also published as a museum "Catalogue" in 1864. The acquisition of fresh material compelled him in the next year to write his "Coleoptera Atlantidum," an arduous critical work of nearly 700 pages, followed in 1867 by the "Coleoptera Hesperidum," a valuable descriptive account of the species of the Cape Verde Archipelago, visited in 1866. His last contribution to geographical entomology, "Coleoptera Sanctæ-Helenæ," 1877, contains a multiplicity of unexpected developments (especially after the supposed exhaustion of the productions of the island in Mr. Melliss's work), and shows that St. Helena is the home of a special family, *Cossonidæ*, to which Mr. Wollaston had always devoted attention, having himself described no less than 255 new species in it, as against 67 described by all other naturalists, living or dead.

Of his other works, it may suffice to mention one on the "Variation of Species," published in 1856, and another, "Testacea Atlantica," that will, alas, be posthumous (though complete), being a descriptive account of the land-shells of his favourite hunting-ground.

The amount of work in these publications and in others not referred to, is astonishing, especially to those who know the extreme precision (both in manipulation and writing) and the weak physical condition of the author. Mr. Wollaston became a Fellow of the Linnean Society in 1847, and was also a Fellow of the Cambridge Philosophical Society, but, beyond his university degree, sought no other honorary distinction. He was, we believe, in his fifty-seventh year at the time of his death. E. C. R.

NOTES

WE may remind our readers that on this day, a century ago, one of the great reformers of science—perhaps the most celebrated naturalist of all times—Linné, breathed his last. His name is too familiar to our readers to necessitate any biographical remarks on our part. His countrymen will doubtless commemorate the day in a fitting manner, and the sanctum at Upsala University, Linné's room, which is still preserved in its original state, will, we are sure, be visited by many a scientific pilgrim.

AT the last general meeting of the Royal Academy of Sciences of Brussels, the five years' prize for natural sciences was awarded to Prof. van Beneder, of Liége, the son of the celebrated zoologist of Louvain.

THE Emperor of Austria has recently awarded the large gold medal "for art and science" to the well-known African traveller, Dr. Oscar Lenz.

THE African traveller, Herr Gerhard Rohlfs, is now organising an expedition for the investigation of the eastern part of the Great Sahara. He will be accompanied by a number of scientific men, amongst others by Prof. Zittel, of Munich. Tripoli will be the head-quarters of the expedition, and its first efforts will be the exploration of the mysterious oases, Wajanga and Kufara, in the south of Anjila, which have never been visited by any European travellers.

AT Frankfort-on-the-Main a new society has been formed with the sole object of watching over the interests of chemical industry.

AMONGST the students of Strassburg University the idea has ripened to erect a monument in memory of Goethe as the most eminent representative of German culture, and as the ideal of a German student. The monument is to stand in front of the new University Building, and is to represent the poet as he appeared at the time of his sojourn at Strassburg, in the prime of youth and strength, and in the costume of that period. Most of the professors of the University regard the idea favourably, and the inhabitants of the city are confidently expected to do the same.

ANOTHER Pompeii has been accidentally discovered in the neighbourhood of Mount Gargano, near Manfredonia. There were found an ancient temple of Diana, a magnificent portico about twenty metres long, with an underground necropolis of great extent. A large number of important inscriptions has already been forwarded to, and exhibited by, the National Museum of Naples. The discovered city is the ancient Sipuntum, near Arpinum, mentioned by Strabo and Titus Livius. The houses are nearly twenty feet beneath the cultivated soil. This town was at the time ingulfed in consequence of a terrible earthquake. The Italian Government has ordered researches to be made on a large scale.

WE are glad to learn that a telegram received at Rome from Cairo announces that the Marquess Antinori had arrived at Zeyla, from which he intended to start at once for Italy. It is not known, however, as yet whether he is alone or accompanied by other members of his expedition.

MR. STANLEY has left Alexandria for England by Brindisi. He is expected to visit Rome, Marseilles, and Paris, on his way home, and speak on his work to the geographical societies of these cities. The Khedive invested Mr. Stanley with the order of the Grand Cross of the Medjidie, accompanied by another order of the next grade, thus conferring upon Mr. Stanley the title of Grand Officer of the Order of the Medjidie.

M. GAUTHIER VILLARS has published the new issue of the *Annuaire* of the Bureau des Longitudes of France, which contains a large number of geographical data. It is the first time that such a quantity of interesting numerical data has been collected in this small volume. In addition the volume contains two essays, one by Dr. Janssen on Solar Photography, and the other on Cosmical Meteorology by M. Faye. The latter denies any connection to exist between either solar spots, magnetic disturbances, or the motions of Jupiter, and the positions of the moon and variations of weather.

THE death is announced of General La Marmora, who always took a lively interest in the progress of science in Italy, and often gave his substantial aid to the establishment of practical scientific schools.

SIGNOR MENGONI, one of the greatest architects of Italy, builder of the well-known Vittorio-Emanuele Gallery at Milan, has fallen from the great arch of that building, whilst giving directions for the completion of this his life-work; he died instantly.

MESSRS. MACMILLAN have in preparation the first part of a "Course of Instruction in Zootomy," by Prof. Huxley, assisted by Mr. T. J. Parker. This part will consist of directions for the dissection of readily-obtainable examples selected from each of the classes of the vertebrata, accompanied by full descriptions of the parts displayed.

WE notice the appearance of a very interesting Russian work by M. Nemirovich-Danchenko, entitled "The Land of Cold," being a description of the author's travels in the White Sea to the coast of Russian Laponia, to Kandalaksk Bay, Novaya Zemlya, and Waigatz Island. The work has no pretensions to be scientific, but it is full of interesting and useful information on the inhabitants of the regions visited. The able descriptions are chiefly devoted to the life of the walrus- and seal-hunters, but it contains, besides lively pictures of such life, abundant statistical data as to the state of those industries, and descriptions of the varied manners in which they are carried on in different parts of Northern Russia. An important part of the work is devoted to descriptions of Samoyedes, Korels, Zyrians, Yuraks, Chukchees, Kamchadalians, Lapps, and Ural Cossacks, based on the author's own notes and other recent information. The work, extending to 520 pages, is illustrated with twenty-five full-page illustrations, and is written in the attractive style characteristic of the author, who is well known in Russia.

THE anniversary meeting of the Vienna Geographical Society was held on December 18. The Society now numbers seventy honorary, 132 corresponding, and 641 ordinary members. The Austrian Minister for Public Instruction has granted a yearly subsidy of 1,000 florins to the Society for the period of three years, and this sum, as well as other donations it has received, have enabled the council to enlarge the Society's library, which during the past year was increased by 234 new works and nineteen geographical views, as well as to facilitate materially the publication of scientific works, and to support geographical exploration. The receipts of the Society during 1877 were 7,332 florins, the expenses 7,110 florins. The President, in his report, announced that the scientific investigations made in Central Africa by Dr. Oscar Lenz and Lieut. Lux, will soon be published, and that the Austrian traveller, Dr. Emil Hollub, after a sojourn of nearly three years in South Africa, will shortly return to Austria.

PHYLLOXERA, that pernicious enemy of the vine, which hitherto had mainly restricted its devastations to the wine-growing districts of France and Switzerland, seems lately to be gaining ground in Germany as well. It is announced that it has appeared in a vineyard at Rauschwitz, near Glogau, as well as in a viticultural establishment at Plantières, near Metz. In the former case the vines had been purchased last spring from one of the numerous horticulturists of Erfurt. The necessary measures are being taken to prevent the spreading of the plague. In France phylloxera seems also on the increase; at Saint Medard and other places of the Gers Department the vines are covered by such masses of the insect that the latter can easily be seen by the naked eye, which is generally not an easy matter.

A NEW weekly serial for horticulturists has been published since January 1 at Berlin under the title *Der deutsche Garten.*

THE contract made between Alsace, Baden and Switzerland, for the protection of the fisheries in the Rhine and its tributaries, has recently come into force. The states mentioned agree to issue similar laws with regard to fisheries, and to further, in every possible way, the maintenance and increase of the valuable species of fish both in the Rhine and in the Lake of Constance. The contract has been signed for the space of ten years, and the participation of the other Rhenish states is much desired.

WE have received another volume of Brehm's "Thierleben," being the third volume on the mammals.

THE observations of shooting stars made in August last at the Royal Observatory of Brussels by M. Houzeau, and at Menin, showed according to a note in the *Bulletin* of the Belgian Academy (Nos. 9 and 10), that the number of these bodies was this year rather small, not exceeding seven per hour on August 9, and sixteen on August 11; on August 10 the sky was covered with clouds.

IN the last session of the Naturforschende Gesellschaft of Görlitz the President, Dr. Peck, made an interesting communication on a newly-discovered enemy of the carp. It appears that large numbers of the spawn of this fish are attacked by the Water-bug (*Ranatra linearis*), which fastens itself firmly on the back of its prey with its forefeet, and by means of its sharply-pointed trunk, sucks out the small amount of blood in the young organism. A series of experiments conducted in some large establishments for fish culture show that the only method of fighting this new foe is to drain the ponds dry and restock them with fish.

A CONSIGNMENT of soles and turbot was sent from the Southport Aquarium on Thursday last to America in charge of Mr. Mather, agent to Prof. Baird, United States Commissioner of Fish and Fisheries. If they arrive safely they are destined to be turned adrift in the Bay of Massachusetts. It appears that while so many members of the *Pleuronectidæ* are common enough on the American coast, soles and turbot are entirely unknown. Hence a journey to England was arranged by Prof. Baird to see if these desirable fish could not be safely transmitted across the Atlantic.

THE members of the Scientific Club will learn with regret that Mr. Logan Lobley, F.G.S., has tendered his resignation of the office of secretary to the Committee of the Club.

WE regret to record the death, on December 22, of Mr. James Whatman Bosanquet, F.R.A.S., M.R.A.S., &c., who was distinguished by his researches in biblical chronology and Assyrian history. He helped forward in many ways the investigations by Mr. George Smith, by Boscawen, and others, which have resulted in the recent famous discoveries. His valuable suggestions with reference to certain solar eclipses as bearing on the subject have frequently been acknowledged by the Astronomer-Royal and by Mr. Hind.

THE death of M. François Vincent Raspail, one of the deputies for Marseilles, is announced. The deceased deputy, who was born in 1794, achieved scientific distinction early in life, and for many years past has held a high reputation on account of his chemical researches. Notwithstanding these scientific pursuits, M. Raspail throughout his life took an ardent and active part in political affairs.

Vanity Fair is informed that the Khedive has granted to a Dutch Company the right of draining Lake Mareotis, and utilising the land reclaimed. Its area is about 75,000 acres, and the company has bound itself to hand over to the Viceroy a certain proportion of the crops raised.

WE have received the first number of the *Revue Internationale des Sciences*, which we recently announced as about to appear. There are two original papers, one by M. Balbiani, on "The Importance and Rôle of Embryogeny," and the other by Prof. von Nägeli, on "The Lower Fungi and the Decompositions which they determine." The rest of the number is mainly occupied with reports of societies.

THE *Gardener's Chronicle* learns with much pleasure that Mr. Bentham has finished the "Flora Australiensis," and that the seventh and last volume of this useful work will shortly appear. The first volume was published in 1863, so that the work has proceeded at the rate of one volume every two years. Not a very rapid rate, it is true; but still it compares favourably with the pace of other publications of the same kind. Mr. Bentham has had the advantage of Baron von Mueller's co-operation in this great work.

A DANISH agricultural journal recommends to those of its readers who wish to provide themselves every winter with a sufficient supply of ice to last during the whole of the summer the following simple means of increasing the thickness of ice during mild winters:—Long and intense cold is necessary to produce a coating of ice of more than two or three inches' thickness upon a surface of water of any considerable extent. But if a hole is made in the ice and the surface from time to time covered with a shallow layer of water, even moderately cold weather will suffice to freeze this water, and by repeating the experiment ice of ten inches or a foot in thickness is obtained without much difficulty. The Danish journal therefore proposes the use of portable pumps to be placed into the ice-holes for the purpose described.

THE apparatus used by M. Cailletet for the liquefaction of the gases was constructed by M. Ducretet, the philosophical instrument maker, and was put into operation in the laboratory of the Paris Normal School during last week, where it has been visited by a number of scientific men.

Two shocks of earthquake were felt at Beachburg, Renfrew co., Ontario, on the morning of December 18 last, the first being between the hours of one and two, the last between five and six o'clock. The latter was so severe as to shake the houses and arouse the inmates from their beds. Beachburg is situated in the same district in the Ottawa Valley in which the earthquake of November 4 was felt most severely.

THOSE who have visited that charming watering-place, Tenby, in South Wales, will know how exceptionally rich the locality is in fossils, sea-shells, and especially in bone caves, some of which contained human remains and stone implements. Mr. Smith of Gumfreston, who has just died, is celebrated for the researches he made in the limestone caves and barrows of the neighbourhood, and his collection of bones, implements, urns, &c., is most extensive and interesting, and, on the authority of Prof. Rolleston, one of the most complete ever got together by a single individual. Through the liberality of Mr. Chas. Allen and others, the whole of the money for the purchase of this collection is forthcoming, but only on condition that a suitable building shall be provided to hold it. At its last meeting the British Association made a money grant for the further examination of the Tenby bone caves, so that it is of the utmost importance to science that a good local museum should be established to prevent these most valuable specimens being scattered all over the country. Those of our readers who really wish practically to help in promoting the cause of local museums have now an opportunity of doing so by forwarding subscriptions to Charles Allen, Esq., 10, Norton Tenby, South Wales. At the same time the people of Tenby and of Pembrokeshire generally will surely have public spirit enough and a sufficiently clear perception of their own interest not to let this fine collection slip through their hands.

Mr. Denis D. Redmond writes from Dublin in reference to Dr. Röntgen's telephone alarum, calling attention to one which he has found very effectual. He simply sends the current of an ordinary magneto-electric machine through the instrument, which produces a loud hum that is distinctly heard many yards away.

The last number of the *Isvestia* of the Russian Geographical Society contains three letters from M. Potanin from Khobdo and Ulassutai, which, though written in January, March, and July, reached the society only in October. The winter in Khobdo was very cold; the thermometer stood in January as low as – 27° Cels. at noon, and even – 37° at seven o'clock in the morning; but the western gales brought a much warmer temperature, those of October 15, November 24, and December 24, having been the heaviest, and the last causing a rise of temperature from – 19°·8 to – 0°·4 Cels. There was little snow, so that the birds could easily find their food, and M. Potanin has noticed no less than fifty species (the insectivorous *Poaoces hendersonii* was among them), which wintered at Khobdo. In March M. Potanin started for Hami. He crossed the eastern part of the Altai Mountains, the Altain Nuru, and soon reached the Gobi Steppe, which takes two days to cross, one night having to be passed without food for the horses and without water. On the southern frontier of the Steppe he was at the Chinese town Santaru. Thence he crossed the Mechin-ola Chain, which runs parallel to the Tian-Shan, and entered the Barkul depression. Hami was reached on May 23, and the travellers, who were kindly received by the authorities, stayed for some time. They returned thence to Ulassutai, *i.e.*, after having crossed the chain mentioned above, turned east, following a series of Sart's settlements at the northern foot of the eastern part of Tian Shan, or Karlyk-Tagh, covered with perpetual snow. At Nom-Tologoy settlement they turned north, crossed for a second time the Gobi Steppe, and afterwards the Altai ridge, and reached Ulassutai on July 25. A survey was made throughout the route, and collections of birds and plants, especially alpine, were obtained. From Ulassutai M. Potanin intended to visit the almost unknown tracts at the sources of the Yenissei, Lake Kosogol, and thence to return by way of Lake Ubsa-nor to Biysk.

The *Allgemeine schweizerische Gesellschaft für die Gesammten Naturwissenschaften*, of Zurich, has just published the second part of its volume for 1877, which contains but one, but a very elaborate treatise, on the spiders of Switzerland. The paper occupies no less than 320 quarto pages, and is accompanied by six well-drawn plates. The author is Prof. Hermann Lebert, and his work is a most valuable addition to zoological science.

A new ethnographical museum is about to be erected in Paris, and is to contain everything that is of any value in relation to the science of ethnography.

The new volume of the *Popular Science Review* commences well. The January number has several good articles, that on "The Old and the New Chemistry" being specially interesting.

In reference to our note last week on the specimens in the Westminster Aquarium, it is the specimen of *Menobranchus lateralis* which is said to be the first shown in England.

The additions to the Zoological Society's Gardens during the past week include a Macaque Monkey (*Macacus cynomolgus*) from India, presented by Mr. F. Wood; a Striped Hyæna (*Hyæna striata*) from Arabia, presented by Capt. F. Cotton; a Red and Yellow Maccaw (*Ara chloroptera*) from Cartagena, presented by Capt. King; a Naked-eared Deer (*Cervus gymnopis*) from Venezuela, presented by Mr. Cyril Graham; a Robben Island Snake (*Coronella phocarum*) from South Africa, presented by Messrs. Rice and Jamrach; a Macaque Monkey (*Macacus cynomolgus*) from India, deposited.

AMERICAN SCIENCE

In the December number of the *American Journal of Science and Art*, Mr. Holden collates various observations, by the Herschels and others, on the trifid nebula M 20, discovered by Messier, June 5, 1764, who, however, gives no details concerning it. The result of the inquiry is to show (1) that from 1784, when Sir William Herschel first described it somewhat in detail, to 1833, the remarkable triple star observed in the nebula, was centrally situated between the three nebulosities; (2) from 1839 to 1877 the triple star was not centrally situated, but involved in one of the nebulosities (A). The idea that the triple star has a large proper motion being thought improbable, it is concluded that the nebula has undergone marked changes of position, or brilliancy, or both, during the period 1784 to 1877. The conjecture was thrown out by Sir John Herschel, that "perhaps this singular object has a proper motion."

In a recent survey of the Connecticut Valley, one of the most interesting features is the discovery of a massive gravel ridge, often nearly covered by the alluvium of the highest terraces extending from Lyme, N. H., to Windsor, Vt. (twenty-four miles) It occupies nearly the middle of the valley, and resembles the gravel ridges that have been known under the various names of *kames*, in Scotland, eskers in Ireland, and asar in Sweden. The theory of the origin of the kames, commonly accepted, is that they were heaped up through the agency of marine currents, during a submergence of the land. It seemed impossible to account thus for the kames in the Connecticut and Merrimack valleys (one is found in the latter also), which, being bordered on both sides by high hills, would have been long estuaries open to the sea only at their mouths, and therefore not affected by oceanic currents. The date of their formation is known to be between the period when the ice-sheet moved over the land, and that closely following, in which the more recent and modified drift was deposited in the open valley from the floods that were supplied by the melting ice; and Mr. Warren Upham, who describes these kames, is thus led to attribute their formation to the action of the glacial rivers, which flowed in channels on the surface of the ice-sheet; the kames having been formed at or near their mouths, extending along their valleys, as fast as the ice front retreated.

Among many important discoveries made last summer by the United States Fish Commission are those of two new species of fishes, named respectively *Macrurus bairdii* and *Lycodes verrillii*. Particulars of these and of a number of other unusual forms are communicated by Messrs. Goode and Bean.

The Museum of Yale College has recently received the greater portion of the skeleton of a huge reptile which proves to be one of the most remarkable animals yet discovered. It was found by Prof. Lakes and Engineer Beckwith in upper Jurassic beds in Colorado on the eastern flank of the Rocky Mountains. The present species (*Stegosaurus armatus*) was probably thirty feet long, and moved mainly by swimming. Some of the teeth preserved have compressed crowns and are inserted in sockets (one is 112 mm. long, greatest diameter of crown, 24 mm.), others are cylindrical and are placed in rows, either in thin plates of imperfect bone or in cartillage (the latter may prove to be dermal spines). The body was protected by large bony dermal plates (one of these was over three feet in length).

Prof. Marsh also contributes a notice of some new Dinosaurian reptiles from the Jurassic formation.

The employment of chromic acid in various volumetric determinations is recommended by Mr. Hinman, who gives examples of his mode of procedure.

We learn from the *New York Tribune* that the last earthquake in the West was supposed to have radiated from a locality in Nebraska that has been popularly regarded as the site of a volcano. Prof. Samuel Aughey, of the Nebraska State University, has recently made an examination of the ground. The seat of disturbance is on the banks of the Missouri, in Dixon County, about thirty-six miles from Sioux City. A bluff, about 1,100 feet long and 160 feet high, sloping at an angle of 60° to 80° toward the river, is at present the place where the phenomena are most exhibited, but other bluffs at a few miles' distance have been similarly affected. On the bluff sounds were heard proceeding from the interior, especially on placing the ear to the ground. Flames sometimes broke forth, occasionally at night. Steam escaped from crevices. On digging into the bluff, intense heat stopped the work after proceeding a few feet. Selenite, alum, and magnesic sulphate in crystals were abundant. Prof. Aughey regards these features as not volcanic in the usual of the term, but simply the result of local chemical action. The formation is cretaceous. The bluff is capped by calcic carbonate. Beneath are shales containing ferric bisulphide in crystals of pyrites. Below the shale is a soft limestone, containing carbonates of magnesia and alumina. The chemical reactions consequent upon part of the soil being soaked with water after its fall toward the river, have been the decomposition of the pyrites, the production of sulphuric acid, and the attack of the acid on the alkaline carbonates. The heat evolved in the first of these reactions is, of course, very great; in the latter part the violence must be increased by the liberation of carbonic anhydride. All the authenticated disturbances are thus easily explained. Prof. Aughey does not connect them with the earthquake.

Prof. J. L. Campbell, of Washington and Lee University, has been collating and discussing the data for the great meteor which was seen in many parts of Virginia on the afternoon of November 20. He concludes that its height was about 100 miles; but this estimate is merely approximate. Its course seems to have been 8° or 10° west of north. Its explosion appears to have taken place over the south-east corner of Halifax County, about fifteen or twenty miles a little south of west from Clarksville, 100 miles from Richmond, eighty from Lexington, and fifty-five from Raleigh. It was a meteor of unusual size and brilliancy, and detonated loudly when it exploded.

The corner-stone of a building for the accommodation of the Davenport Academy of Natural Sciences was laid on October 4, and is almost the first edifice west of Chicago intended for purely scientific purposes; the building is expected to be ready for occupation this month. The Academy is a young institution, which has grown very rapidly, and has already assumed a prominent position among establishments of this kind in the United States. This is due principally to the excellent character of its *Transactions,* filled with interesting information, and especially rich in subjects relating to American archæology. Part 1 of vol. ii. has been sent us.

If the descriptions are not overdrawn, a remarkably convenient small steam engine has been invented in Philadelphia. It is an oscillating engine, attached to a tank holding about two gallons of water. The boiler is of about a quart capacity; the steam-chest half that size; the whole concern occupies a space of about 10 inches square and 18 high, and weighs 35 pounds. It is designed for use with any sort of light machinery, and is said to be suitable for a variety of domestic work. The details of the contrivance are not yet stated, but assurances are given that it cannot, under any circumstances, explode; that it is as manageable as an ordinary gas burner, since the inventor has succeeded in dispensing with water and steam gauges and automatic floats, so that the whole apparatus is simple, and no skill is required to operate it. The kitchen of the future is expected to contain one of these engines, to chop hash, turn the coffee-mill and the roasting-jack, sift ashes, and mangle the family linen.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

EDINBURGH.—The matriculation returns for the past year have now been completed, and show a considerable increase in the number of students in residence over any former period. The numbers on the register for 1876 were 2,302, for 1877 they amount to 2,560. The students are divided between the several faculties as follows:—In the faculty of arts, 953 students; of theology, 67; of law, 364; and of medicine, 1,176. The ground is now being cleared for the erection of the University Extension Buildings, which, with the aid of the Government grant, will be vigorously proceeded with, and thus furnish the additional accommodation so urgently required for the increasing number of students, and for the fuller development of the teaching resources of the University.

TAUNTON COLLEGE SCHOOL.—A first-class microscope by Smith and Beck, a handsome clock and centre-piece, a purse containing 136*l*., and addresses emblazoned on parchment, from the old boys, the parents, and the friends of the school, have been presented to the Rev. W. Tuckwell, on his leaving Taunton.

FRANCE.—M. Bardoux will propose to the French Parliament, during its present session, to organise, in each department (there are eighty-nine), a high primary school after the model of the École Turgot, one of the municipal schools of Paris. He will also introduce a bill for enlarging the Sorbonne, the traditional headquarters of the University.

BERLIN.—The professorship of botany, which has been vacant since the death of Alexander Braun last March, is now to be filled by Prof. Eichler, of Kiel, who has accepted a call to this position as well as to the directorship of the Botanical Gardens in Berlin. He enters upon his duties next April. During the *interim* the gardens are under the direction of Prof. Koch.

GÖTTINGEN.—The present attendance at the University is 909, a slight decrease on the past summers. They are divided among the faculties as follows: theology, 86; medicine, 115; law, 275; philosophy, 433. The representation of foreign countries is unusually small, with the exception of America, which supplies a contingent of 27. The corps of instructors, numbering 116, includes 9 in theology, 26 in medicine, 14 in law, and 67 in philosophy and science.

ERLANGEN.—The University is attended at present by 448 students, a slight increase on the number of the past summer. Bavaria contributes 305, the remaining 143 coming from the other parts of Germany and from abroad. Medicine includes 110, pharmacy 56, chemistry and the natural sciences 32, mathematics and physics 10.

SCIENTIFIC SERIALS

THE current number of the *Quarterly Journal of Microscopic Science* commences with Dr. Roberts' address at the Manchester meeting of the British Medical Association on the doctrine of Contagium Vivum and its application to medicine.—Following this is Part 4 of Mr. Archer's *résumé* of recent contributions to our knowledge of "Fresh-water Rhizopoda," including the Rhizopoda, Monothalamia, Monostomata.—Prof. Carl Vogt's account of *Loxosoma* is abstracted, with notes, by Rev. T. Hinks. The genus is confirmed as a Polyzoon, and allied to *Pedicellina* Its ova and reproductive buds are described, as well as the different organs, in detail.—A paper by Prof. Arthur Boettcher treats of the results arrived at by treating red blood corpuscles with alcoholic solution of corrosive sublimate.—Dr. Klein contributes a paper on the minute anatomy of the epidermis in small-pox of sheep.—The last paper is Prof. Lankester's important notes on the embryology and classification of the animal kingdom; comprising a revision of speculations relative to the origin and significance of the germ-layers. This paper has since been separately published.

Annalen der Physik und Chemie, No. 10.—On the border angle and the expansion of liquids on solid bodies, by M. Quincke.—On the specific heat of vapours and their variations with the temperature, by M. Wiedemann.—Determination of the ratio of the specific heats for air at constant pressure and constant volume by the velocity of sound, by M. Kaiser.—On the internal friction of solid bodies (continued), by M. Schmidt.—On the doctrine of aggregate states, by M. Ritter.—Manometric method of determining the specific gravity of gases, by M. Recknagel.—On the disaggregation of tin, by the Editor.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, Dec. 13, 1877.—"Experimental Researches on the Electric Discharge with the Chloride of Silver Battery," by Warren De la Rue, M.A., D.C.L., F.R.S., and Hugo W. Müller, Ph.D., F.R.S. Part I.

The paper in question deals mainly with the striking distance between terminals of different forms in air and in other gases at ordinary atmospheric pressures; and in air at reduced pressures short of the partial vacua of the so-called vacuum tubes.

The authors have found that the discharge of the battery, with one or two poles in the form of a point, presents several interesting phenomena which precede the true jump of the spark, and which do not occur with other forms of terminals; for example, discs or spherical surfaces. With 8,040 cells the striking distance between a paraboloidal point, positive, and a disc is about 0·34 in. (8·64 millims.), but there is always a luminous discharge. Very apparent, far beyond the distance measurable by their micronometer-discharger, namely, 1·16 inch (29·5 millims.), as they have before stated.[1]

The current which passes during the luminous discharge which precedes the jump of the true spark is extremely feeble, in comparison with that which takes place after the spark has passed and the voltaic arc has formed; even when the point and disc are not more distant than ·02 inch beyond the striking distance 0·34 inch for 8,040 elements, it is only $\frac{1}{17}$th part of it.

---

[1] *Proc. Roy. Soc.*, 1876, vol. xxiv. p. 169.

The appearance of the discharge is very different, according as the point is positive or negative; it is intermittent in both cases, but is much less discontinuous when the point is negative than when it is positive, as can be seen with a microscope having a rotating minor placed in the bend of the body between the objective and eye-piece. The appearances observed are shown in the wood engravings which illustrate the paper.

Between a point and a disc the spark is longest with the point positive, when from 5,000 to 8,000 cells are used; but for a less number of elements, 1,000 to 3,000, it is longest when the point is negative.

The length of the spark is greatly influenced by the form of the point; thus with a point in the form of a cone of 20 degrees the striking distance is 0·184 inch with 5,640 cells, and 0·267 inches with 8,040, while with a point approaching a paraboloid in form, and with the same base and of the same height as the cone, it is 0·237 inch with 5,640 cells, and 0·343 inch with 8,040.

The striking distance between a point and a plate is in accordance, very nearly with the hypothesis of this distance, increasing in the direct ratio of the square of the number of elements, at all events up to 8,040 cells, thus[1]:—

Number of cells ...	1,000	2,000	3,000	4,000	5,000	6,000	7,000	8,000
	in.	in.	in.	in.	in.	in.	in.	in.
Distance observed ...	0·0051	0·0221	0·0554	0·103	0·159	0·222	0·286	0·352
Distance calculated...	0·0055	0·0220	0·0495	0·088	0·1375	0·198	0·2695	0·352

Between plane, spherical, or cylindrical surfaces, the striking distance does not follow this law; on the contrary, the increase is nearly, but not quite, in the ratio of the number of cells.

	1,000 cells. in.	8,000 cells. in.
Between spherical surfaces	0·0050 ...	0·0810
Plane „ „	0·0104 ...	0·0852
Two concentric cylinders	0·0071 ...	0·0991

The striking distance between two paraboloidal points was found to be with—

1,080 cells. in.		8,040 cells. in.
0·005	.. ...	0·401

The nature of the metal used for terminals has, in almost all cases, no influence on the length of the spark, but there is one striking exception, namely, in the case of aluminium; when an aluminium point is used the spark is longer than with points of all other metals tried, in the ratio of 1·242 to 1.

The length of the spark is different in various gases; for example, air, oxygen, nitrogen, hydrogen, and carbonic acid, and the ratio between the lengths of spark in various gases varies with the forms of the terminals. The length of the spark bears no simple relation either to the density of the gas or its viscosity.[2]

The paper contains an account of a few experiments on the length of spark in air at different pressures, from 141·5 millims. to 760 millims. Between a point and a disk the length of the spark increases nearly, but not quite, in the ratio of the dilatation; but between two spherical surfaces it increases far more rapidly, and it is possible that at a certain degree of rarefaction the striking distance may be coincident for spherical surfaces and points.

When a strong resistance is interposed in the circuit, 4,000,000 ohms for example, the discharge is completely changed in character; instead of the ordinary spark and production of the voltaic arc, very brilliant snapping sparks pass between the terminals at more or less rapid intervals, exactly like the sparks of a small Leyden jar. Then pierce a piece of writing with minute holes.

It has been found that an accumulated charge of a condenser of 42·8 microfarads capacity, charged with the potential of 3240 cells, produced neither an elongation nor a contraction of a metallic rod 0·2 inch when suddenly discharged through. This charge deflagrates 10·5 inches of platinum wire 0·0125 inch in diameter.

More dense sparks were obtained with one of App's coils for producing 6-inch sparks when the primary was connected with 1080, 2280, 3480 chloride of silver cells, than when it was used with a zinc-carbon, bichromate of potash battery of six cells producing a current 300 times as great, thus showing the influence of high potentials in inducing secondary currents.

These currents of high potentials have also a marked effect in inducing magnetism, when the actual current is taken into account.

The second part of the paper, which is in course of preparation, will deal with the discharge in rarefied gases, in the so-called vacuum tubes.

Chemical Society, December 20, 1877.—Dr. Gladstone, president, in the chair.—The following papers were read:—On the constitution of the terpenes and of camphor, by Dr. Armstrong.—Communications from the laboratory of the London Institution, by Dr. Armstrong.—On the hydrocarbons from *Pinus sylvestris*, with remarks on the constitution of the terpenes, by Dr. Tilden. The author has examined the terpenes from Russian turpentine oil and *Oleum foliorum pini sylvestris*. He considers that there are probably only three isomerides amongst the natural terpenes, and suggests a formula for these bodies derived from that of diamylene.—On citric acid as a constituent of imperfectly ripe mulberry juice, by Dr. Wright and Mr. Paterson. This juice was found to contain 26·83 grm. of citric acid and 3·26 grm. of potash salts per litre; the authors point out that it may be valuable as an antiscorbutic, and as a substitute for lime juice.—On cuprous chloride and the absorption of carbonic oxide and hydrochloric acid gas, by J. W. Thomas. The author suggests a ready method of making a solution of cuprous chloride for gas analysis, but finds that although a solution of this salt absorbs carbonic oxide readily, sixty-three per cent. of the gas may be again liberated on neutralising the solution with potash. To avoid such an error he just neutralises the solution of cuprous chloride with ammonia and in this way prepares a solution which introduces into the absorption tube neither free ammonia nor free acid, but which absorbs carbonic oxide with facility. The author has also observed that a saturated solution of ammonic sulphate absorbs hydrochloric acid gas with great readiness, forming an acid salt and ammonic chloride.

Anthropological Institute, December 11, 1877.—Dr. John Evans, D.C.L., F.R.S., president, in the chair.—Dr. James F. N. Wise was elected a member.—Mr. Worthington Smith exhibited some objects from Maiden Bower, and a series of camera lucida drawings of several stone monuments in Wales.—Mr. A. Jukes Browne, F.G.S., exhibited a series of flint flakes, scrapers, and arrow points from Egypt, and read an interesting paper on the subject. He described the geological formation of the country round Helwan about sixteen miles south of Cairo, whence the flints were obtained, and explained the denuding action of the Nile in this locality. He thought that the finding of separate implements in each site pointed to there having been flint manufactories on those spots which, moreover, were near the hot springs. No adzes or celts were found, but fragments of horses' teeth split into long pieces were among the flints. The flints used in the manufacture of these implements were pebbles found on the lower plateau which had been washed down from the hills of eocene limestone above, the upper beds of which abound in siliceous concretions of various sizes.—Mr. Jukes Browne also exhibited some flint implements from a site on the borders of the Fens in Lincolnshire, which appeared to have been a station or manufactory similar to those at Helwan. The president and Mr. Moggeridge made some remarks on the above.—Mr. J. Park Harrison communicated a further report on the "cave-pits" at Cissbury. He said that the galleries belonging to it, and the pits adjoining, appeared to have been used as places of shelter and concealment for some considerable time after they were excavated. No evidence existed at present that they were habitations. One shaft, to which there was access from the cave-pits, was found to have been left unfinished with the horn tools lying where the work had been interrupted. Several small oval pits, the largest only 5 feet long, and 4 feet 6 inches deep, were met with this autumn for the first time in the neighbourhood of the shafts. Among their contents were sling stones and small pieces of flint and fractured rubbing-stone bearing marks of fire, fragments of pottery of various dates, a few flint implements and many flakes; also three weights formed of chalk (similar to some found in Mr. Tindale's pit); a carding-comb, a small iron hook, and three pieces of burnt clay with the impress of sticks on wattles. A few bones of calf, roebuck, pig, and goat, with two or three shells, were the only animal remains. They would appear to have been preserved by the charcoal and charred matter in contact with them. If the little pits were graves they would appear to have been used for secondary interments, or been otherwise disturbed. The absence of human bones might be due to atmospheric influence, as in many other cases of burial by inhumation. There was black mould at the bottom of all the little pits. Coarse potsherds, flint implements, and burnt pebbles, were also found in the neighbourhood of the small pits near the surface, and may possibly mark the spots where flint-workers of an earlier period were interred. A discussion followed in which several members took part.

[2] *Proc. Roy. Soc.*, vol. xxvi. p. 227.

Institution of Civil Engineers, December 18, 1877.—Annual General Meeting.—Mr. George Robert Stephenson, president, in the chair.—The numbers of the several classes of members on November 30, 1877, were:—Honorary members, 16; members, 925; associates, 1,670; and students, 448; together, 3,059, as against 2,844 at the same date last year, showing an increase at the rate of about 7½ per cent. The income proper for the year had amounted to 9,903*l.* 5*s.* 3*d.*, the life compositions and admission fees and building fund (all regarded as capital), to 2,113*l.* 13*s.*, and the dividends on trust funds to 462*l.* 16*s.* 6*d.* The general expenditure had reached 10,278*l.* 2*s.*, and the payments on account of trusts were 486*l.* 8*s.* 5*d.* The disbursements were thus 374*l.* 16*s.* 9*d.* in excess of the income. The funded property (including the cash balance) belonging to or under the control of the Institution, was now 38,773*l.* 4*s.* 11*d.*—Mr. John Frederic Bateman, F.R.S., was elected president.

Victoria (Philosophical) Institute, January 7.—Mr. C. Brooke, F.R.S., in the chair.—It was announced that exactly one hundred members had joined during the past year.—A paper on limitations in nature was read by Mr. S. R. Pattison, F.G.S.

EDINBURGH

Royal Society, December 17, 1877.—Sir William Thomson, president, in the chair.—Mr. Alexander Buchan read the report of the deputation from the Society to Upsala to assist in celebrating the four hundredth anniversary of the University of Upsala.—Mr. J. B. Hannay then read a paper on a new method of determining the cohesion of liquids by the size of its normal drop, which he considered was that obtained by allowing the drops to succeed one another as rapidly as possible. He found that the weight of the drop of liquid dropping from a column of the same liquid increases at the rate at which the drops follow one another. This, he thought, was due (1) to the fact that the rate of flow of liquid through the neck of the drop was faster when drops succeeded rapidly, and (2) because the flow lasted for a longer time. He found also that cohesion decreases with rise of temperature, but rather quicker than the density.

PARIS

Academy of Sciences, December 31, 1877.—M. Peligot in the chair.—M. Faye presented the *Annuaire du Bureau des Longitudes* for 1878.—The following papers were read:—On the constitution of the solar surface and on photography regarded as a means of discovery in physical astronomy, by M. Janssen. Photography has two advantages over optical observation. If the time of exposure be accurately determined, so as to prevent superposition, or what may be called *photographic irradiation*, the true relations of luminous intensity of the object are expressed. Further, when the luminous action is very short the photographic spectrum is reduced to a narrow band near G; thus very tolerable photographic images of the sun may be had with simple lenses of long focus, and chemical achromatism is much more easily realised than optical. M. Janssen has so arranged that the time of luminous action can be reduced to $\frac{1}{1000}$ of a second in summer. The images are more latent and require slow development, &c. But they throw new light, especially on the solar granulations, which are found more or less of spherical form; the irregular grains are made up of small spherical elements. The state resembles that of our clouds. These spherical elements and their distribution probably result from a breaking up by gaseous currents. The luminous power of the sun, then, resides chiefly in a small number of points of its surface, and the spots are not the principal element of the variations that star undergoes.—Constitution and brecciform structure of the meteoric iron of Santa Catharina (Brazil); deductions from its characters, concerning the history of meteoritic rocks, and especially the habitual association of carbon with sulphide of iron, by M. Daubrée. The association referred to may be explained by the action of sulphide of carbon on iron. If an iron bar be thus treated at a red temperature, it gets coated with a crystalline substance which has the characters of pyrrhotine.—On the order of appearance of the first vessels in shoots of *Fœniculum vulgare* and *dulce*, by M. Trécul.—Note on waves and eddies of various kinds in a canal whose current is alternately intercepted and renewed, and in which the depth can be varied, by M. de Caligny.—On the condensation of gases supposed incoercible, by M. Cailletet. Pure dry nitrogen, compressed to 200 atmospheres at + 13°, then suddenly expanded, condenses distinctly in small droplets; The liquid retires from the walls to the centre. Pure hydrogen compressed to 280 atmospheres and expanded, gave momentarily, a very fine mist. Air was also liquefied by a direct experiment. M. Berthelot corroborated M. Cailletet's account.—M. De Lesseps announced that the *personnel* of the first scientific and hospital station of the International African Association had reached Zanzibar. They had met Stanley and got useful advice from him.—On a storm which occurred over the south part of the Suez Canal on the night of October 23–24. In a few hours an artificial lake of about five million cubic metres was formed on the west side of the canal by the rains.—Kinematics and dynamics of current waves on a liquid spheroid; application to the evolution of the elliptic protuberance about a spheroid deformed by attraction of a distant star, by M. Guyon.—On a new experiment on liquefaction of oxygen, by M. Pictet. The oxygen jet in the electric light showed a white central part (of liquid or even solid elements) and an exterior blue part, indicating return to the gaseous state.—On a note by M. Boussinesq on conditions with limits in the problem of elastic plates, by M. Levy.—On a theorem of M. Villarceau; remarks and consequences, by M. Gilbert.—On a new kind of bird of nocturnal prey from Madagascar, by M. Milne-Edwards. This belongs to the same zoological type as the white owls, but has osteological peculiarities.—The peripheric organs of the sense of space, by M. Cyon. Having shown that there are intimate relations between the semicircular canals and the centres of innervation of the muscles of the eye, he considers that sensations caused by excitation (through the otoliths) of the nerve terminations in the ampullæ of these canals, through movements of the head, serve to form our notions of the three dimensions of space.—On the evolution of red corpuscles in the blood of superior animals, viviparous vertebrates, by M. Hayem. The red corpuscles are developed from small, colourless, delicate, very alterable elements termed *hæmatoblasts*.—Experiments proving that there is during life a figured ferment in typhoid human blood, by M. Feltz.—On the cause of spontaneous alteration of eggs; reply to a reclamation of M. Gayon, by MM. Bechamp and Eustache.

THE DENSITY OF LIQUID OXYGEN

THE magnificent experimental methods devised by MM. Cailletet and Pictet have already begun to increase the number of the "Constants of Nature." M. Pictet, although in a neck-and-neck race he was beaten by Cailletet in the liquefaction of hydrogen, has left his competitor in the rear with regard to a result of the first importance on the density of oxygen. The noble rivalry between the École Normale Supérieure of Paris and the Atelier de Physique of Geneva bids fair not only to continually increase in interest, but to become the central feature in the progress of physical science for some time.

A telegram from M. Pictet announcing that hydrogen had been solidified was sent to M. Dumas on January 11. The illustrious chemist read the telegram at a sitting of the Société d'Encouragement, of which he was the chairman, and which was holding its regular semi-monthly meeting on that very evening. M. Dumas reminded his hearers with his wonted force and propriety of expression, that in the first edition of his "Traité de Chimie," published about forty years ago, he had called hydrogen a *gaseous metal*. He said he had been led to hold this view by seeing how small was the affinity of hydrogen for metals and how great for metalloids.

M. Dumas said moreover that his peculiar ideas had received some degree of confirmation from the discovery of the large conductibility of hydrogen for heat and electricity, but that the first real demonstration had been given by MM. Cailletet and Pictet. It was for him a great satisfaction having lived long enough to see that most important fact established so clearly, "*That you may feel certain, gentlemen, that in drinking a glass of water you are certainly absorbing a metallic oxide.*"

M. Pictet, in the experiments, the results of which were telegraphed to M. Dumas, as we have seen, prepared the hydrogen by the decomposition of potassic formiate by means of potassic hydrate. This reaction, according to Berthelot, gives the gas of the utmost purity. The pressure was commenced at 8.30 P.M., it was increased gradually, and in a little more than half an hour (at 9.7) it reached 650 atmospheres. At this moment the pressure remained stationary for some seconds, the stop-cock was opened, and a jet of a *steel blue colour* escaped with a strident noise, comparable to that heard when a bar of iron is plunged into water.

This jet suddenly became intermittent, and the spectators observed a hail of solid corpuscles projected with violence on the ground, where they produced a crackling noise. The stop-cock was then again closed, the manometer indicating 370 atmospheres. This slowly descended to 320, at which point it remained stationary for some minutes. Then it rose to 325. The stop-cock was again opened, the jet was now so intermittent, that it was believed that an actual crystallisation of hydrogen (!) had gone on inside the tube. This was proved by the fact that liquid hydrogen flowed out of the jet when the temperature was increased by the stoppage of the pumps.

M. Dumas, considering oxygen as belonging to the sulphur group, and isomorphous bodies as having the same atomic volume, *i.e.*, the quotient obtained when the atomic weight is divided by the density, had concluded that, the atomic volume of sulphur being $\frac{32}{2}$, that of oxygen would be $\frac{16}{1}$, and reciprocally, that the density of liquid or solid oxygen would be $\frac{16}{16}$, that is the atomic volume divided by the atomic weight = 1, which is the density of water.

M. Dumas having communicated these considerations to M. Pictet, has elicited a most interesting response from him. He writes :—

"You arrive at the expression of the density of liquid oxygen as being represented by $\frac{16}{16} = 1 = \delta$ in the solid state, and probably the liquid one also, neglecting the variation due to expansion.

"I have the great satisfaction of being able to announce to you the complete experimental demonstration of the theoretical views enunciated by you now some time ago at Geneva. This demonstration has been arrived at as follows :—

"I know directly and very exactly—

"I. The exact volume of the interior of the wrought iron shell and the volume of potassic chlorate decomposed into oxygen and potassic chloride.

"II. The temperature of the shell at the moment of complete decomposition.

"III. The volume of the tube in which the condensation of oxygen is brought about.

"IV. The pressure before and after condensation.

"V. The pressures indicated by the manometer after two or three successive jets, till the moment the point of saturation is reached, and after which the gas issues in a gaseous form.

"These various data, combined with the gaseous density pressure and temperature lead me to the conclusion that a difference of 74·26 atmospheres on the manometer represents the variation of pressure corresponding to the condensation of oxygen in the tube immersed in the carbonic acid.

"This variation has been exactly observed in the three last experiments which I have made with the assistance of many of my colleagues here at Geneva.

"The quantity of liquid oxygen which we had in the tube was 45·467 grammes, corresponding to a volume of 46·25 cubic centimetres. But it is possible that the highest part of the thin tube had some centimetres in length not occupied by the liquid. This may explain the difference of 0·8 gramme found.

"Moreover, very volatile liquids have such considerable expansions that it is indispensable to have exactly the temperature to which they are subjected, in order to determine their true density. However this may be, there is an absolute verification, within small limits, of error of the theoretical calculation regarding this physical constant."

In addition to this important result, in another experiment, M. Pictet has used polarised light to determine the presence or absence of solid particles of oxygen in the jet. The jet was illuminated by means of the electric light, and observed with two Nicol prisms. A very strong polarisation was observed, indicating the presence of solid particles, which in all probability were really solid particles of oxygen.

FRANKLAND'S RESEARCHES IN CHEMISTRY

Experimental Researches in Pure, Applied, and Physical Chemistry. By E. Frankland, Ph.D., D.C.L., F.R.S. &c. (London: John Van Voorst, Paternoster Row.)

THE numerous and valuable investigations of Dr. Frankland in general chemistry are so well known, that chemists will doubtless regard the issue of his collected researches with lively satisfaction, partly on account of the ease with which the various memoirs can be referred to in the fine volume before us, but chiefly because the work is likely to prove of special value as an aid in the higher education of chemical students.

Any criticisms of the statements of fact or of theory contained in such a set of "collected researches" would be so clearly out of place in NATURE, that we need offer no apology for dealing with the work before us from a general rather than from a technical point of view. Indeed, almost all the *matter* contained in the volume has long been the common property of all engaged in the pursuit of chemistry, while the *manner* in which the investigations are presented to the reader is alone new. The chief interest of the work as a whole is due to the fortunate circumstance that its varied contents have been grouped by the distinguished author of the researches, who has bound them together with a species of commentary that enables the reader clearly to appreciate the relations of the parts in each line of inquiry, and to obtain such glimpses into the working of the mind of the investigator as the study of formal papers can rarely afford.

The subject-matter of this fine volume of rather more than 1,000 pages is conveniently divided into three sections. Section I. contains the author's researches in Pure Chemistry; Section II., those in Applied Chemistry; and Section III., the investigations that belong to the physical side of the science.

Section I. is fitly introduced by a chapter on the peculiar system of notation now employed by Dr. Frankland. This introduction was rendered necessary by the translation of the older formulæ employed in the earlier memoirs into those more recently adopted by the author. Although Dr. Frankland's system of notation is undoubtedly interesting, we fear that its use throughout the volume will detract from the educational value of the work in the eyes of those chemists who think that the expressions in common use can be made to serve the same purposes as those employed in the South Kensington School.

As the work stands, however, the chapter in question is useful in its place, and it may induce some chemists to adopt the author's system who have hitherto held aloof from it.

The first of the series of researches given is that on the transformation of cyanogen into oxatyl. This well-known inquiry was carried on in conjunction with Dr. Kolbe at a time when the investigation of the then recognised "compound radicles" had commenced to excite much interest, more especially in view of Liebig's recently propounded theory of conjugated compounds. The investigation led to the highly important conclusions that most of the organic acids owe their acidity to the presence of the group COOH (the semi-molecule of oxatyl), and that their basicity depends on the number of these groups contained within their molecules; while it was shown that the synthesis of many acids of the acetic series could be effected by the conversion of the cyanogen of alcoholic cyanides into the oxatyl semi-molecule by the action of alkalies. This research has since borne rich fruit, and it seems to have led, almost directly, to the most important of the author's discoveries, namely, to the isolation of the alcohol radicles by the action of zinc on iodides of radicles containing half the number of atoms of carbon. Although this research was one of the most important contributions to synthetic chemistry that had then been made, its full value was not understood till M. Wurtz completed Dr Frankland's work by the discovery of methyl-ethyl, and other mixed radicles, which he prepared by the action of zinc on mixtures of alcoholic iodides, thus filling up the gaps in Frankland's list, and rendering the method a general one for ascending the homologous series.

In the course of experiments on the action of zinc on the iodides of alcohol radicles, Frankland made the remarkable discovery that the metal can unite directly with the alcohol radicles and form the curious and interesting compounds now termed "organo-metallic," of which zinc-methyl and zinc-ethyl are those most commonly known. The author says "zinc-methyl and zinc-ethyl were the first of these bodies with which I became acquainted; they were discovered on July 12, 1849, in the laboratory of Prof. Bunsen at Marburg, during my work on the isolation of the organic radicles. After making the reaction for the isolation of methyl by digesting methylic iodide with zinc, and after discharging the gases, I cut off the upper part of the tube in order to try the action of water upon the solid residue. On pouring a few drops of water on this residue a greenish blue flame several feet long shot out of the tube, causing great excitement amongst those present. Prof. Bunsen, who had suffered from arsenical poisoning during his researches on cacodyl, suggested that the spontaneously inflammable body, which diffused an abominable odour through the laboratory, was that terrible compound which might have been formed by arsenic present as an impurity in the zinc used in the reaction, and that I might be already irrecoverably poisoned. These forebodings were, however, quelled in a few minutes by an examination of the black stain left upon porcelain by the flame; nevertheless, I did afterwards experience some symptoms of zinc poisoning."

The discovery of the large group of organo-metallic bodies and the secondary investigations to which the author was thereby led induced him to propound the theory of "atomicity," now taught in one form or another in our schools of chemistry.

Having discovered the organo-metallic bodies just referred to, Dr. Frankland appears to have turned his attention to the production of analogous compounds containing *unmetallic* bodies united directly with alcohol radicles, and in this direction he was successful, as he showed that boron could be made to afford some highly interesting compounds of the desired kind. This line of investigation, however, was not pursued to any considerable extent, as the author evidently desired to concentrate his attention upon the study of the action of members of the organo-metallic group upon various organic bodies, hoping thereby to succeed in replacing the oxygen of many oxygenated compounds by alcohol radicles derived from zinc-methyl, zinc-ethyl, and allied bodies. In the primary research of this new series, nearly all of which were conducted in conjunction with the late Mr. B. F. Duppa, ethylic oxalate was the subject of experiment, with the result that a portion of its oxygen was replaced by methyl, and the first step taken in the synthesis of acids of the lactic series. A large number of new compounds were discovered, and the relations of the members of the lactic series of acids to each other and to the acrylic and to the fatty group of acids clearly made out. Then followed researches on the members of the acrylic series which were suggested by those on the lactic acids and which also afforded a rich harvest of results.

Up to this point Dr. Frankland's investigations are seen to have been intimately connected with one another and to have resulted in some of the most valuable contributions yet made to synthetical chemistry; but the last research of importance included in this section of the volume seems to stand alone, for it is concerned with the synthesis of acids, ethers, and ketones of the fatty series by a method differing from that previously employed in the important particular that the alcohol radicles were substituted for hydrogen and not for oxygen. These new investigations resulted in the discovery of a mode of effecting the synthesis of the acids of the fatty series and of bodies related to them, of dissecting their molecules, and thus, in some measure, of determining their structure. Although these researches were not directly connected with those that preceded them, there can be scarcely a doubt that they were suggested by the insight into the constitution of the acids gained in the course of Dr. Frankland's previous researches.

A few short papers—on Gas Analysis, on the Composition of Air from Mont Blanc, on the Analysis of Organic Compounds containing Mercury, and on the Combustion of Iron in Compressed Oxygen—bring Section I. to a close.

Section II. contains the author's researches on Artificial Light, on Drinking Water, on the Purification of Foul Water; together with miscellaneous work in Applied Chemistry. Section III. includes Dr. Frankland's valuable memoirs on the Influence of Atmospheric Pressure on Combustion, on the Spectra of Gases of Vapours (an investigation carried out in conjunction with Mr. Lockyer), on the Source of Muscular Power, and on Climate.

The contents of these two sections are much too interesting to be lightly passed over—and those of Section II. in some degree challenge criticism—but we must leave them for consideration in another article and now return to Section I. This section forms just half the book, and by far the most important half. In fact Dr. Frankland's work is so naturally divisible into two parts that we regret he has not issued it in two volumes rather than in its present form, for its value as a work of reference would not have been lessened thereby, while the section of chief educational importance (Section I.) would have been rendered more easily accessible to students. This is, however, but a trifling fault—if a fault it happens to be—but the really important fact remains that we can point students to the volume before us for a clear and detailed account of some of the most remarkable researches of our time in synthetic chemistry. It is difficult to over-estimate the importance of inducing senior students to consult original memoirs rather than abstracts of researches. The temptation to rest content with a statement of results is great, but we have no hesitation in expressing the opinion that the careful experimental study of a single good memoir, on a subject suited to the capacity of the student, is of far greater value to him than the immediate knowledge of the contents of a volume of the "Abstracts" given in the *Journal* of the Chemical Society, useful though these are when properly employed. The publication of such groups of researches as Dr. Frankland's will, we believe, do much to promote the kind of higher chemical education referred to, and to foster a taste for research amongst senior students of chemistry.

J. EMERSON REYNOLDS

(*To be continued.*)

OUR BOOK SHELF

Bericht über die Thätigkeit der botanischen Section der schlesischen Gesellschaft im Jahre 1876. Erstattet von Prof. Dr. Ferdinand Cohn, zeitigem Secretair der Section.

THIS is a journal of the proceedings of the ten ordinary and one extraordinary meetings of the Silesian Society held during the year 1876. The chief contributors are Professors Goeppert and Cohn, and their communications relate to a great variety of subjects. The most important paper of Goeppert's is on the effects of the cold of December, 1875, on the vegetation in the Breslau Botanic Garden, much interesting information being given on the action of cold on plants, the effects of snow in protecting vegetation, and the action of frost on roots. Another interesting paper, by the same author, is on Plant Metamorphoses. The indefatigable industry of Prof. Cohn is well shown in this journal, as he contributes a large number of valuable papers. His recent visit to Britain affords materials for two papers, while a short communication on Spontaneous Generation is interesting on account of the ingenious form of the tube in which the experiments were made, the shape being that of a capital N turned upside down. The other papers of interest are chiefly connected with the newly-published "Cryptogamic Flora of Silesia," noticed a short time since in our columns. The last paper is by Uechtritz on the Phanerogams of the Silesian Flora, and occupies a large part of the whole *Bericht*.

A List of Writings Relating to the Method of Least Squares, with Historical and Critical Notes. By Mansfield Merriman, Ph.D. (From the *Transactions* of the Connecticut Academy, vol. iv., 1877, pp. 151–232.)

MR. MERRIMAN is already favourably known as the author of a good text-book on the "Elements of the Method of Least Squares." In this work he gave a short "list of literature," and said he could easily have extended its limits; indeed he hoped some time to publish an extended list. All students of this branch must be greatly indebted to Mr. Merriman and to the Connecticut Academy for this excellent critical list of writers. There are 408 titles, classified as 313 memoirs, 72 books, and 23 parts of books, dating from Cotes (1722) down to 1876. Of these 408, 312 are described from actual inspection. We could wish for similar lists in other branches, for then much time would be saved and students could easily determine what books would be most advantageous to them, and also get an idea of what had already been done by previous investigators. There are numerous clerical errors, easily to be corrected, but we are surprised that so well-informed and painstaking a writer should call Sir W. Thomson, Thompson, and Dedekind, Dedakind, as he does on all occasions when their names occur.

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.

The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.]

The Radiometer and its Lessons

I AM sorry to have again to correct Mr. Stoney; but I cannot allow the statements contained in his letter to pass unnoticed.

1. There is nothing in my earlier paper that is "*admittedly erroneous.*" If there is error in these papers I am not aware of it.

2. These papers do not "conclude with Prof. Reynolds's own expression of opinion that residual gas is not the cause of the force observed by Mr. Crookes." Nor have I ever held or anywhere expressed such an opinion.

3. In the passage to which Mr. Stoney refers, Clausius does not imply that the law established by himself and Maxwell, viz., that the only condition of thermal equilibrium in a gas is that of uniform temperature, depends on the mean path of the molecules; and it was this law that I instanced as being at variance with Mr. Stoney's assumptions (1) that gas is a perfect non-conductor of heat; (2) that a layer of gas across which the temperature varies can exist in a state of thermal equilibrium without the passage of heat from the hotter to the colder part. Mr. Stoney has nowhere that I can see given any proof of these assumptions, and I venture to prefer the authority of Professors Maxwell and Clausius, supported as it is by the whole evidence of facts.

4. Mr. Stoney says that I have excluded the polarisation of gas from my explanation. Mr. Stoney has not, that I am aware, defined what he means by polarisation, but if he measures the polarisation of a gas conducting heat by the excess of momentum carried across any ideal surface in one direction over and above that which is carried in the opposite, this polarisation is independent of the length of the mean path, and forms an essential part of my explanation.

There is one statement in Mr. Stoney's letter which is not erroneous. He says:—"I cannot find anywhere in Prof. Osborne Reynolds's writings an explanation of the thing to be explained, viz., that the stress in a Crookes's layer is different in one direction from what it is at right angles to that direction."

I do not at all admit that this is "the thing to be explained," and I am quite sure that Mr. Stoney would find no explanation of it in my writings.

In the passage quoted above Mr. Stoney has, for the first time, so far as I know, expressly stated his belief that Mr. Crookes's phenomena depend on such a difference of stress. I have thought all along that his views were based on such an assumption, but I did not like to take it for granted. It is almost a pity, if I may use the phrase, that he did not express himself thus clearly at first, as in that case I might have done before what I am about to do now, viz., prove definitely that such a condition of stress can have nothing to do with the cause of Mr. Crookes's results—that, so far from explaining, such a condition of stress is inconsistent with, these results, and this, not in mere matters of detail, but as regards the fundamental direction in which the force acts.

Throughout all the experiments that have been made one invariable law as to the direction of motion has been found to maintain, which is that the force always tends to drive the vanes or bodies in the direction of their colder faces. Thus when a body is free to move in a sufficiently rarefied medium, if its front be heated it will move backward, while if its front be cooled it will move forward, always moving towards its colder face. There are no exceptions to this rule.

Let us now suppose that we have two bodies, A and B, free to move in a sufficiently rarefied medium. Suppose A to be initially hot and B cold, while the medium and surrounding surface are at the mean temperature of A and B. Then, owing to the radiation of heat between the two bodies, that side of A which is opposite to B will be cooled faster, and hence be colder than the other side of A. Hence according to the law stated above, A must move towards B, and this it is found to do by experiment. On the other hand, that side of B which is opposite to A will become heated by radiation faster, and hence become hotter, than the other side of B, and hence B will move away from A. Thus if both bodies were free to move, we should have B running away from A, and A running after B.

This aspect of the phenomenon is perhaps the most paradoxical that presents itself; it is nevertheless in strict accordance with experiment, and it was by instancing this case that I was enabled to show that the force could not by any possibility be directly due to radiation (see *Phil. Trans.*, vol. 166, p. 728).

The same reasoning now enables me to show, just as conclusively, that the force which causes the motion in the bodies cannot be due to the stress, in the layer of gas which separates the bodies, being greater in the direction joining the bodies than it is at right angles to this direction. For the only effect of such a difference in the stress would be to cause the bodies to separate; therefore, instead of A following B, it would be forced back in the direction of its hottest side, or in a direction opposite to that in which it is found experimentally to move.

This case, therefore, shows the fundamental error of Mr. Stoney's view. Although he allows that the intervening gas is the medium of communication, he assumes, none the less, that the force acts directly between the two bodies (the heater and cooler), in which case action and reaction must be equal between the two bodies. Experiment, on the other hand, shows conclusively that the force acts independently between each body and the gas which surrounds it; the pressure being always greatest on the hottest side. The force which acts on the body reacts on the gas, causing it to move in the opposite direction, and the wind thus caused tends to carry all opposing obstacles with it. Hence, in the case above, the motion given to the air at the one body must to some extent affect the opposing surface, but this surface forms only one obstacle, while the action of the wind is distributed throughout the entire chamber, in which it acts in the manner so beautifully shown by Dr. Schuster's plan of suspending the vessel. A simple analogy to what happens in the case of A and B is furnished by two steamboats, the one following the other. The water thrown back by the screw of the first would stop the second, but only to a small extent.

When answering Prof. Foster in a former letter, I said "that it is contrary to the kinetic theory that the increase resulting from rarefaction in the mean path of the gaseous molecules should favour the action." In making this statement all I meant to imply was that the action was independent of any relation between the mean path and the distance of the hot surface from the cold surface, which was the only point in question. Although my statement was strictly true in this sense, it appears to me, on further consideration, that it might include more than I intended.

I hope that nothing I have said, either in my earlier papers or in this controversy, has led any one to suppose that I regarded my explanation as entirely complete. I suggested, and to some extent established, the true source of the force, namely the heat communicated to the residual gas, and although now my suggestion appears to have been universally accepted, it may be remembered that at the time my first paper was written the only other suggestions as to the cause of the motion observed by Mr. Crookes were of a widely different character. As regards the working out of the detail of my explanation, there has been one point which I could not quite see through, viz., the influence which the hot molecules receding from the surface might have on the rate at which the cold ones would come up, and although I have been trying to satisfy myself on this point ever since my first paper was published, it is only within the last three months that I succeeded.

Now, however, I have arrived at a result which, although somewhat unexpected and striking, will, I hope, be found to reconcile what has hitherto appeared to be anomalous in the phenomena already known, and to have suggested certain hitherto unexpected phenomena which now only await experimental verification.

Sun-spots and Terrestrial Magnetism

PRECISELY because the article (NATURE, vol. xvii. p. 183) on "The Sun's Magnetic Action at the Present Time," is by so able a mathematical physicist as Mr. John Allan Broun, and because of all sides of the solar problem there is none wherein he is so *facile princeps* as the magnetic, I venture to think this a good opportunity for asking a question which has troubled me much of late, and which is this:—

The sun-spot cycle and the terrestrial magnetic diurnal oscillation cycle are looked on now generally as being, if not actual cause and effect, at least as equally both of them effects of one and the same cause, and necessarily, therefore, synchronous. Yet if we inquire of the sun-spot observers the length of their cycle, they declare it (as see Prof. Rudolph Wolf's admirable and exhaustive paper in the last volume of the *Memoirs* of the Royal Astronomical Society) to be 11·111 years. While if we ask the magnetic men the length of the cycle of their needle manifestations, they (as in Mr. Allan Broun's first paragraph on p. 183) declare it as confidently to be 10·5 years.

Wherefore I would request to be kindly informed if the maxima of the two cycles do approximately agree just now, where will they be, relatively to each other, after a dozen cycles hence? And the answer may or may not assist in clearing up certain apparent anomalies in the Edinburgh earth-thermometer observations. PIAZZI SMYTH

On the Insects of Chili and New Zealand

IN Mr. McLachlan's note "On Some Peculiar Points in the Insect Fauna of Chili" (NATURE, vol. xvii. p. 162), I see, with surprise, the remark that "the large islands of New Zealand furnish us with no indication whatever of forms parallel with those found in Chili," for it is well known that many Lepidoptera belonging to European genera do occur in New Zealand, although, perhaps, neither *Argynnis* or *Colias*. Amongst a small number of Lepidoptera from New Zealand which lately came into my hands, I notice species of the following European genera:—*Sesia*, *Cloantha*, *Nonagria*, *Heliothis*, *Hybernia*, *Larentia*, *Fidonia*, *Cidaria*, *Coremia*, *Camptogramma*, *Asthena*, *Acidalia*, *Scoparia*. Except in the case of *Sesia tipuliforme*, it is not probable man has had any hand in the introduction of them. None, except the *Sesia*, are identical with European species, although several approximate, and the causes which have led to the existence of *Agynnis* and *Colias*, in Chili, are probably the same as those which have planted the insects I have named in New Zealand.

In Mr. Darwin's "Origin of Species," Chapter XII., we find a suggested Explanation of the Presence of the Forms of the Northern Temperate Zone in South America and New Zealand in the occurrence of alternate glacial epochs at the North and South Poles, and although the observations especially refer to plants, they are applicable to the insects which would, doubtless, accompany them in their supposed migrations. Perhaps it is not an entirely satisfactory explanation, and with his usual candour, Mr. Darwin admits that it does not meet all difficulties. In describing the wanderings of the plants, Mr. Darwin uses terms (figurative of course) which endow them with extraordinary if not voluntary powers of locomotion, as, indeed, they would seem to require in reality, for effecting such wonderful migrations, and as regards insects Mr. McLachlan goes further, and suggests that some of them "mistook the points of the compass and went southward."

Now the pertinacity with which the Lepidoptera adhere to particular plants and stations, and prefer death to change of either, is a much more noticeable character than their ability to emigrate, and seems to me a serious bar to the acceptance of a theory involving great changes of food and a double journey across the equator; possibly some of the polyphagous species might survive it, but even these, according to Mr. McLachlan, appear to have got a little muddled in their reckoning. Most of the insects I have named are eminently select in their diet, and how are we even to conceive of the wingless female of Hybernia performing the vast journey?

I do not know that we have evidence that change of climate induces migration of the Lepidoptera. There is a large colony of *Bryophila perla*, which has been stationed on an old wall here for the last twenty years, and although there are miles of similar lichen-covered walls in the neighbourhood, I have never seen a specimen fifty yards from head-quarters, and even under the threat of a new glacial epoch, I do not think it would consent to move on.

In saying there are no indications of similar forms on the northern portions of the Andes, I am not sure whether Mr. McLachlan refers to Lepidoptera or Trichoptera, so I will mention that I have received several species of *Colias* captured on the eastern Cordillera of New Granada. The genus probably ranges through the whole chain of the Andes.

Douglas, Isle of Man, January 2 EDWIN BIRCHALL

Macrosilia cluentius

IN NATURE (vol. viii. p. 223) I have spoken of a *Sphinx* which, with its proboscis of 0·25 metre length, would be capable of obtaining nearly all the nectar of *Anagræcum sesquipedale*. Lately my brother, Fritz Müller (Itajahy, Prov. St. Catharina, Brazil), sent me the wings of another specimen of the same species, and Dr. Staudinger, of Dresden, stated by comparison of these wings with the Sphingidæ of his collection that the name of the species is *Macrosilia cluentius*, Cramer.

Lippstadt, January 9 HERMANN MÜLLER

Meteor

I TAKE the liberty of forwarding the following particulars relative to a meteor which I saw on Sunday last at 4h. 24m. P.M., that is to say, about twenty minutes after sunset. As, however, the day had been very fine, there was not only full daylight in the west, but only a trace of twilight in the north-west direction, in which I saw the meteor. I may add that the sky was slightly overcast by watery clouds in that direction:—

Point from which seen, Salthill, near Kingstown; direction in which seen, north-west; elevation above horizon, 10° to 15°; length of luminous "tail," 5° to 6°; inclination from vertical, about (towards south) 10°; time, 4h. 24m. P.M.; colour of tail and of globe of explosion, light blue.

Judging from the elevation and from the fact of its being visible notwithstanding the strong twilight and the interposed clouds, I conclude that this meteor must have been remarkably brilliant and that it exploded over or beyond the West Coast of Ireland. It is for these reasons that I take the liberty of calling attention to it, as others may have seen it under more favourable conditions. P. W. REILLY

Royal College of Science for Ireland,
Stephen's Green, Dublin, January 15

Philadelphia Diplomas

IN NATURE, vol. xvii. p. 183, there appears a note by Dr. C. M. Ingleby on the "Philadelphia Diplomas." Permit me to say that the only institutions in Philadelphia legally authorised to grant medical diplomas are the University of Pennsylvania, a school which has long ago celebrated its centenary, and the Jefferson Medical College. The so-called University of Philadelphia is a hybrid concern, the medical department of which is under the management of the Eclectic Medical School.

January 10 RICHD. C. BRANDEIS

Great Waterfalls

I SHALL be much obliged if you, or any of your readers, can inform me in what book I can find accounts of any of the following great waterfalls:—The Tequendama Fall, near Sta. Fé de Bogota, South America; the Cauvery Falls, near Seringapatam, India; the Alatau Falls, Alatau Mountains, Central Asia; the Guava, or Guayra Falls, on the Alto Parana, South Brazil; Falls of the Rio Grande, near Guadalajara, Mexico. These great falls, five of the most remarkable in the world, are shortly noticed in books of geography, but I have hitherto been unable to obtain any detailed particulars or description of them.

Eltham, January 7 ARTHUR G. GUILLEMARD

BIOLOGICAL NOTES

SELF-FERTILISATION OF PLANTS.—This subject, around which the genius of Mr. Charles Darwin has thrown a halo, seems likely to give rise to further controversy. The Rev. G. Henslow, in a communication laid before the first meeting this session of the Linnean Society, gave an exposition of the views he had arrived at; these in many respects being at variance with those promulgated by Mr. Darwin. The author acknowledged how indebted he stood towards the latter, whose vast storehouse of facts and close reasoning necessitated constant reference to his writings; but the author's own deductions therefrom, and additional researches, nevertheless, confirmed him in hesitating to accept some of Mr. Darwin's conclusions. According to Mr. Henslow, the chief facts and bearings of the self-fertilisation of plants may thus be summarised: 1. The majority of flowering plants are self-fertile. 2. Very few are known to be physiologically self-sterile. 3. Many are morphologically self-sterile. 4. Self-sterile plants become self-fertile by (*a*) withering of the corolla, (*b*) its excision, (*c*) loss of colour, (*d*) closing, (*e*) not opening, (*f*) absence of insects, (*g*) reduction of temperature, (*h*) transportation. 5. Highly self-fertile forms may arise under cultivation. 6. Special adaptations occur for self-fertilisation. 7. Inconspicuous flowers are highly self-fertile. 8. Cleistogamous flowers are always self-fertilised. 9. Conservation of energy in reduction of pollen. 10. Relative fertility may equal or surpass that of crossed plants. 11. It does not decrease in successive generations. 12. It may increase. 13. Free from competition self-fertilised plants equal the intercrossed; (*a*) as seedlings, (*b*) planted in open ground. 14. They may gain no benefit from a cross from the same or a different stock. 15. They are as healthy as the intercrossed. 16. They may be much more productive than flowers dependent upon insects. 17. Naturalised abroad they gain great vigour; and (18) are the fittest to survive in the struggle for life.

PHYSIOLOGICAL ACTION OF NICOTIN.—About twenty years ago the Rev. Prof. Haughton called attention to the fact that there was an antagonism between the actions of nicotin and of strychnia. His experiments were on frogs. About ten years afterwards Dr. Wormley experimented in the same direction with cats; and some five years ago Dr. Reese performed a series of experiments with these drugs on dogs. Not satisfied with the results of any of these experimenters and recognising the great importance of the subject, Dr. Haynes has made a long series of experiments on dogs, cats, rabbits, and rats, and after some 143 experiments has come to the following conclusions:—"The recorded cases of strychnia poisoning treated by tobacco are extremely unsatisfactory. If they prove anything it is merely that tobacco is a powerful emetic." "Haughton's experiments on this subject (really only two in number) were performed in such an unscientific manner as to be utterly valueless." "Strychnia and nicotin are in no degree antagonistic poisons." "Strychnia increases the convulsive action and does not diminish the motor paralysis of nicotin." "Nicotin (even in paralysing doses) increases the convulsive action of strychnia." "Both poisons cause death by paralysing the respiratory organs. They may affect respiration in different ways, but the result is the same." Animals may be killed by injecting together doses of the two drugs which, singly, are not fatal. (*Proceedings* of the American Philosophical Society, vol. xvi., No. 99.)

GLASSY SPONGES.—Drs. W. Marshall and A. B. Meyer have published a memoir, as one of a series of communications to the Zoological Museum at Dresden, "on some new or little-known sponges belonging to the Hexactinellidæ found in the Philippines." It seems but the other day since one could have numbered on the fingers of one hand all the known species of this family, so well known to many by that beautiful typical form, the Venus's flower-basket (*Euplectella*), and now the number of described species is very large. In 1872 one of the authors (Dr. Meyer) was staying at Cebú one of the Philippine group, where *Euplectella aspergillum* is a regular article of trade, quoted at so much a dozen, and where it is not surprising that he should discover a number of other lovely forms in this memoir described and figured. Among the more interesting forms are the following:—*Hyalocaulos simplex*, *Myliusia zittelii*, and two species of *Aulodictyon*, all of these found living attached to the basal portion of *Euplectella*. *Semperella schultzei* is figured of a natural size from a specimen twenty-one inches in length, and figures of the spicules of the various new species are also given.

A MALE NURSE.—The interest of the reproduction of Batrachians is by no means yet exhausted. A Spanish naturalist, Jimenez de la Espada, has recently discovered additional facts respecting *Rhinoderma darwinii* (of Chili), which was first made known by Mr. Darwin. He finds that the supposed viviparous birth of the young from the female is a very different phenomenon. It is the males which are the nurses, and they have an extraordinary brood-sac, developed as a pouch from the throat, and extending over a great portion of the ventral surface of the animal. In this cavity a number of living tadpoles were found, in number of individuals, and the length of the tadpoles was about 14 mm. How these are first developed and nourished is not yet known. Dr. J. W. Spengel translates a portion of the Spanish paper in the current number of the *Zeitschrift für wissenschaftliche Zoologie*, vol. xxix. part 4.

STRUCTURE OF CYCADEÆ.—E. Warming, of Copenhagen, publishes (in Danish with French abstract) some fresh researches on this subject ("Recherches et Remarques sur les Cycadées," Copenhagen, 1877). He confirms in general the results previously arrived at by A. Braun and others, from the structure of the ovule and seed, the pro-embryonic characters, the mode of formation of the pollen and pollen-plant, and of the growth of the stem and roots, &c., that the Cycadeæ are very nearly allied to the Coniferæ; and in particular he places them near to the Gingko (*Salisburia adiantifolia*). Among Cryptogams he considers them to come nearest to Marattiaceæ and Ophioglossaceæ among Filicineæ. He proceeds then to discuss the homology of the ovule of Phanerogams, on which he thinks the structure of that of the Cycads—intermediate between Vascular Cryptogams and Angiosperms—throws much light. The phanerogamic ovule he considers to be composed of two parts, of different morphological origin, viz., a nucleus which is homologous with the macrosporangium; and a lobe of the leaf which bears the nucleus, consisting partly of the funiculus and partly of the integuments. In Angiosperms the nucleus rests on the surface of the leaf; in Gymnosperms it is partly imbedded in it. No part of the ovule is of axial origin (*caulome*).

THE BRAIN OF A FOSSIL MAMMAL.—Prof. Cope has been able to take a cast of the cranial cavity of a specie of the Tapiroid genus Coryphodon, from the Wahsatch beds of New Mexico. This has revealed remarkable primitive characters: (1) the small size of the cerebellum; (2) the large size of the region of the corpora quadrigemina; (3) the cerebral hemispheres were small, and (4) the olfactory lobes were very large. The medulla oblongata is wider than the cerebral hemispheres. In profile the brain closely resembles that of a lizard. These characters are so extraordinary that Prof. Cope considers them sufficient to mark a primary division of mammalia, which he, following Owen, calls Protencephala. Prof. Cope describes and gives figures of a cast, the skull cavity, in the *Proceedings* of the American Philosophical Society, vol. xvi., No. 99.

INSECTIVOROUS PLANTS[1]

SINCE the appearance of Mr. Darwin's work on "Insectivorous Plants" the want of direct proof that the plants profit by their carnivorous habits has been somewhat widely felt. Thus we find expressions to this effect by MM. Cassimir de Candolle, Cramer, Duchartre, Duval-Jouve, Faivre, Göppert, E. Morren, Munk, Naudin, W. Pfeffer, Schenk, &c., &c.

The assent which many naturalists have given to Mr. Darwin's explanation of the meaning of the structure and physiological properties of carnivorous plants rests on a sound basis, namely, the impossibility of believing that highly specialised organs are unimportant to their possessor, and the difficulty of giving any rational explanation except the one proposed in "Insectivorous Plants." Mr. Darwin himself felt the desirableness of direct evidence on this head, and the experiments intended to decide the question only failed through an accident. The present research by Dr. F. Darwin is practically a repetition of the same experiments.

---

[1] From a paper "On the Nutrition of *Drosera rotundifolia*," by Franci [illegible]win, M.B., read before the Linnean Society, January 17, 1878.

The widely-spread belief that insectivorous plants thrive equally well when deprived of animal food rests on very insufficient grounds. Many observers have based their opinion on the general appearance of the plants, and in no case has observation been sufficiently extended in point of time or details of comparison. The plan of the present research was therefore (1) To cultivate a large number of plants. (2) To continue observation for a considerable space of time, during which artificial starving and feeding of two sets of plants was to be kept up. (3) To compare the starved and fed plants in a variety of ways and especially as to the production of seed.

With this object about 200 plants of *Drosera rotundifolia* were transplanted (June 12, 1877), and cultivated in soup-plates filled with moss during the rest of the summer.

Each plate was divided into halves by a low wooden partition, one side being destined to be fed with meat, while the plants in the opposite half were to be starved. The plates were placed altogether under a gauze case, so that the "starved" plants might be prevented from obtaining food by the capture of insects. The method of feeding consisted in supplying each leaf (on the fed sides of the six plates) with one or two small bits of roast meat, each weighing about one-fiftieth of a grain. This operation was repeated every few days from the beginning of July to the first days of September, when the final comparison of the two sets of plants was made. But long before this it was quite clear that the "fed" plants were profiting by their meat diet. Thus, on July 17 it was evident that the leaves on the "fed" side were of a distinctly brighter green, showing that the increased supply of nitrogen had allowed a more active formation of chlorophyll-grains to take place. It may be inferred, partly from microscopical examination of the starch in the leaves, but more certainly from the final comparison of dry weights, that the increase of chlorophyll was accompanied by an increased formation of cellulose. From this time forward the "fed" sides of the plates were clearly distinguishable by their thriving appearance and their numerous tall and stout flower-stems.

The advantage gained by the fed plants was estimated in many ways. Thus, on August 7 the ratio between the number of "starved" and "fed" flower stalks was 100 : 149·1. And by comparing the number of stems actually in flower it was clear that the starved plants were losing the power of throwing up new flower stems at an earlier date than their rivals. In the middle of August the leaves were counted in three plates, and were found to be 187 on the starved, and 256 on the fed side—or in the ratio of 100 : 136·9.

At the beginning of September the seeds being ripe, all the flower-stems were gathered, and the plants of three plates were picked out of the moss and carefully washed. As it seemed probable that one advantage of the fed over the starved plants would be the power of laying by a larger store of reserve-material, three plates were allowed to remain undisturbed after the flower-stems had been gathered. The relative number of plants which will appear in the spring on the "fed" and "starved" sides will be a means of estimating the relative quantities of reserve-material.

The following list gives the result of counting, measuring, and weighing the various parts of the two sets of plants. It will be seen the number of plants (judging from the three plates examined) were fairly equal on the starved and fed sides of the partitions so that a direct comparison of their produce is allowable:—

Ratio between the number of starved and fed plants	100 : 101·2[1]
Ratio between weights of the plants *exclusive* of flower-stems	100 : 121·5
Total number of flower stems	100 : 164·9
Sum of the heights of the flower stems ...	100 : 159·9[1]
Total weight of flower stems	100 : 231·9
Total number of capsules	100 : 194·4
Average number of seeds per capsule ...	100 : 122·7
Average weight per seed	100 : 157·3
Total calculated *number* of seeds produced	100 : 241·5
Total calculated *weight* of seeds produced	100 : 379·7

The most important feature in the general result is that the advantage gained by the fed plants is far more conspicuously shown in all that relates to the seeds and flower-stems than in any other part. Thus the ratio between the weights of the plants, exclusive of flower-stems were as 100 to 121·5; while the weights of the flower-stems, including seeds and capsules, were as 100 to 231·9. The highest ratio is seen to be between the total weights of seed produced, namely 100 : 379·7; and this is intelligible, because a store of nitrogen is laid by in the albuminous seeds.

Another point is that the difference between the starved and fed plants is more clearly shown in the comparison of weights than of numbers or heights. It is clear that increase of weight is a better proof of increased assimilation than any other character.

It may fairly be said that the above experiments prove beyond a doubt that insectivorous plants are largely benefited by a supply of animal food, and it can no longer be doubted that a similar benefit is gained in a state of nature by the capture of insects.

ALBERT VON HALLER

ON December 12 last the republic and city of Berne celebrated the centenary of the death of one who is universally recognised as their greatest citizen. The important part played in science by Albert von Haller last century is a sufficient excuse for us, profiting by the occasion of the recent celebration, to enable our readers to appreciate the marvellous aptitude of this eminent man for every kind of work, theoretical and practical; he was at once a statesman, theologian, and poet, as well as a physiologist, anatomist, and botanist.

Albert Haller was born at Berne in October, 1708, of a family originally of St. Gall, one of whose members fell by the side of Zwingli in 1531. Very weak in body, like Isaac Newton, in his infancy, he exhibited, like him, an extraordinary precocity, and his avidity for books was something indescribable. Having finished his classical studies brilliantly and rapidly, he went to Tübingen at the age of fifteen years to study medicine, then soon after to Leyden to follow the clinic of the illustrious Boerhaave, on whose works he at a later time published a commentary which greatly contributed to his renown. Albinus taught him anatomy and J. Gessner botany. At eighteen and a half years he obtained the degree of doctor, and afterwards attended, in London, the teaching of Dr. Winslow. After a sojourn at Paris he returned to Switzerland and studied mathematics with Jean Bernoulli, and that with such ardour that his friends were constrained to look after him.

In 1728 he made, with Gessner, his first great Alpine excursion, which, many times repeated, made him, in an eminent degree, master of the Swiss flora. His most celebrated poem, entitled "Die Alpen," was another result of his mountain journeys, which contributed to diffuse among those far away the magic charm of that magnificent scenery.[2]

---

[1] In all cases "starved" = 100.

[1] Therefore the average height of the fed stems is slightly less (100 : 99·9) than that of the fed. But since equal numbers of *plants* are taken, the total yield of flower stems is the fair criterion.

[2] Prince Radzivil, Commander of the Polish Confederates, having at a later period become acquainted with the poem, could not think of anything better to signify to the author his satisfaction, than to send him a commission of Major-General.

His first anatomical instruction was obtained at Bâle, and was continued during five years, after which Haller returned to his native country, where an active medical practice did not hinder him from ever and ever reading to increase the field of his already vast knowledge. He read at table, in journeying on foot or on horseback, during his visits and consultations, which made those shake their heads who could not understand his marvellous clearness of perception.

His botanical labours were then very extensive, and brought him his first encouragement from abroad. In December, 1733, the Royal Academy of Sciences of Upsala received him among the number of its members, and proposals were made to him to become a professor there. At Berne his success was not easy; in 1734 he obtained the modest position of librarian. This was the epoch when, while carrying on his work as a practitioner, he gave himself especially to poetic composition, but which came to an end in 1736.

It was at this time he received a call from the newly-founded University of Göttingen, to go there as Professor of Anatomy and Botany. This call was accepted, and although it was for him the occasion of a great grief, in the death of his wife soon after their arrival, he displayed in this new centre a remarkable activity and capacity. His desire and his plans for the foundation of an anatomical theatre were soon realised. Measures were taken that subjects should not be wanting for dissection; and at the same time conformably to his proposals, a botanical garden was created which soon became one of the most important in Germany. He was the soul of his faculty and of the entire university, and his reputation caused students to flock to Göttingen from all countries, whom he encouraged in every way, prescribing to them various works in connection with his own and for the prompt development of the physiological sciences. He founded at Göttingen the Royal Academy of Sciences, of which he was appointed president, a position he retained to the end of his life, notwithstanding his return to his own country.

It was at this time he published his commentaries on the work of Boerhaave, when he commenced his "Elementa Physiologiæ," his "Anatomical Plates," his "Flora of Switzerland," and other works. In 1749 the King of England appointed Haller his private physician, and confirmed the titles of nobility which had been conferred on him by the Emperor Francis I. The Royal Society of London, the Academy of Stockholm, those of Berlin and Bologna, enrolled him on their lists of members. Frederick the Great of Prussia attempted to get him to Berlin, but Haller would only leave Göttingen to return to Berne, and he decided to do so in 1753. His zeal for public affairs caused him to accept in his native country official functions in which his aptitudes of every kind found their application. Appointed Bailiff of the district of Aigle, near the eastern extremity of the Lake of Geneva, he explored and worked the sources of salt; at Berne he contributed to the creation of an orphanage and a large hospital, upon which he inscribed the beautiful device, "Christo in pauperibus." In 1754 he received from the French Institute the great distinction of being nominated one of its foreign associates; of the eight then existing, three were Swiss—Jean Bernoulli, Euler, and Haller. He regretted that his administrative occupations absorbed much of the time he would have wished to devote to science; and yet even during this period of his life his productiveness was enormous. Besides a large number of monographs and dissertations on subjects in the domains of botany, medicine, anatomy, and physiology, he published more extensive works, such as: Two parts of anatomical plates in folio, a quarto volume of surgical dissertations, four volumes "Disputationes practicæ selectæ," and six volumes of his "Elementa Physiologiæ Corporis humani." He occupied himself more especially with the anatomy of the eye, the formation of the bones, and the comparison of the brains of birds and fishes. He was chiefly original in his experiments on the movement of the blood, in his researches on the development of the chicken in the egg, and on that of the fœtus of quadrupeds, as well as in his teratological studies.

In his physiology he introduced the dominant idea, which was his principal discovery, of irritability considered as a force peculiar to muscular fibre, independent of sensibility properly so called, and differently distributed. In his hands this force became a new law, with which he connected nearly all the animal functions. He can only be blamed, perhaps, for having distinguished it too absolutely and in too decided a manner from the nervous force on which it always depends. As to generation, Haller maintained the doctrine of the pre-existence of germs, and he gave it the most solid support in his studies on the fœtal development. Not knowing the chemical action of the air on the blood he was unable to understand the exact idea of respiration.

All his writings show immense erudition, the fruit of his extensive reading, with the assistance of a prodigious memory. In four Bibliothecæ," published under his auspices at Berne, Zurich, and Bâle, he spoke of 52,000 different scientific works or treatises all known by him and annotated by his hand to make known the text, the sources, and the authors.

A similar erudition rendered him eminently apt at bibliographical work. Thus we have from him in his "Methodus Studii Medici" of Boerhaave a classification of works, in which their degree of merit is distinguished by one, two, or three asterisks. But few living authors were content with the number of asterisks which he accorded to their works, and this attempt made him numerous enemies. He had collected for his use about 20,000 volumes, which were bought after his death by the Emperor Joseph II. and given to the University of Paris.

On many occasions attempts were made to bring Haller back to Göttingen. In 1770 King George III. personally made overtures for this purpose; but the republic of Berne valued too highly his presence to consent to a new departure. The Council, while assuring the king of its friendship and its desire to please him, was opposed to this departure, not being able to be deprived of a man so necessary to the public weal in a place for life created expressly for him, and in view of the general service of the state. The passionate love which he had for his country made him respond in the most efficacious and the most varied manner to the hopes which his fellow-citizens had placed in his activity, more especially in the great start which agriculture took in his time and under his influence.

However, in the midst of so many matters, for which Haller was always of easy access, his health was constantly delicate. With advancing age many infirmities presented themselves which would have arrested a man of less energy, and which led to very painful crises. Gout and insomnia tormented him more and more, and he did not conceal from himself that the use of opium, by means of which he combated them, had serious drawbacks. One of his friends advising to change the *régime*, he replied in Italian:—

> "Sono venti tre ore e mezza."

Haller died December 12, 1777, in his seventieth year, observing till the last moment the ebbing of his life, and indicating at last by a sign the moment when his pulse stopped. But he saw the approach of death with the calmness of a confirmed Christian, having all his life preserved a sincere faith, without fearing more than Newton, Euler, or Linné, that that faith could be contradicted or compromised by the scientific researches which he had pursued with a zeal which has scarcely been surpassed.

E. G.

THE MODERN TELESCOPE[1]

IV.

THE next point to which Mr. Grubb refers is one to which much interest attaches. It is now a long time ago since Sir J. Herschel investigated the effects of differently shaped apertures upon the images of stars. The figure shows the effects they produce due to diffraction.

An effect is also produced on the image if a round, or triangular, or square patch is placed in the centre of the object-glass. With the former the discs of the stars are smaller, and the position of the diffraction rings is changed, so that double stars can thus be measured, while in ordinary circumstances the companion is hidden by one of the rings.

Now in a reflector, unless, indeed, we use the front view, the central patch is always present, and it is to this and to the arm which supports it that the peculiar look of a star in a reflector is due. Mr. Grubb does not hesitate to ascribe to this the great difference of opinion that exists as to the performance of the two classes of instruments, and adds :—

"A veteran and well-known worker with refractors declared 'he never looked into a reflector without drawing away his eye in disgust;' and workers with reflectors cannot understand how the refractor workers can bear that dreadful fringe of colour from the secondary spectrum. The same applies to other matters. Newtonian observers cannot understand how those who observe with refractors or Cassegrain reflectors can bear to strain their neck so in looking up through the tube; while the refractor and Cassegrain workers cannot understand how the Newtonian workers will break their backs sitting or standing bolt upright when they might be reclining comfortably on an easy chair as they do. After all, when this comes to be investigated it resolves itself into but little more than a question of to which telescope the observer has been most accustomed. Each observer becomes in time *wedded to his own instrument*; he has done his work with it, the credit of his discoveries is due to it, and he naturally falls into the idea that no other can be as good."

We next come to those points in which the reflector is stated to be superior to the refractor. These are absence of secondary spectrum, superior applicability for physical work, possibility of supporting mirrors irrespective of size, and handiness of reflectors due to their short focal length, and especially if the Cassegrain form be employed. With regard to the first point, the experiments of Mr. Vernon Harcourt and Prof. Stokes, in which they attempted to produce two kinds of stars with rational or nearly rational spectra, have failed to lead to any great hopes being formed as to ultimate success, and the superior advantage of the reflector in the fact that there is no colour will doubtless long remain. The superior applicability for physical work is much more doubtful. At present we know too little about reflection from metals and many other points to lay down the law with certainty, and in my own opinion Mr. Grubb's dictum is far too absolute with regard to spectroscopic work.

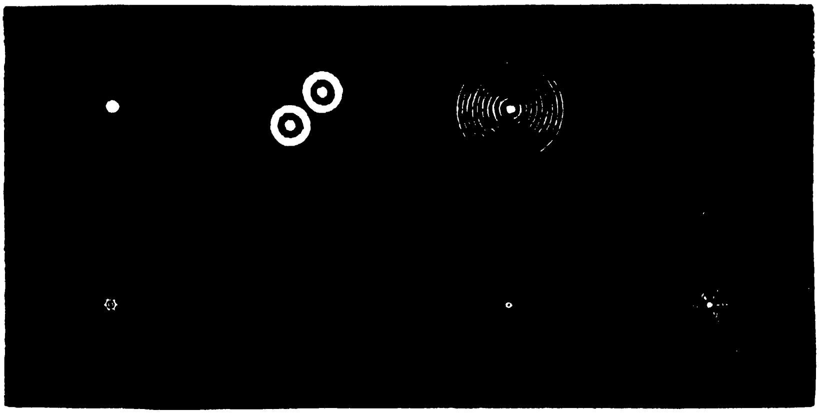

FIG. 10.—Diffraction effects produced by apertures and stops of different shapes (Herschel).

In another part of his valuable paper Mr. Grubb measures the advantage of the reflector with regard to the question of support; he shows that an object-glass may be supported by a central arm without loss of definition, and even that the tube may be filled with compressed air. He says: "The pressure required would be very small. Suppose the objective to be forty inches aperture, and 600 lbs. weight, and that it was purposed to lift $\frac{2}{3}$ of its weight on the air cushion, a pressure of about $\frac{1}{3}$ of a pound to the square inch, or say $\frac{1}{50}$ of atmosphere would suffice, even when the telescope is at its maximum elevation."

The remarks of Mr. Grubb on the practical difficulties which supervene when increased aperture is required, are best given in his own words :—

"It may be said that the difficulty of manufacture is a question for the instrument-maker alone, and not to be discussed by those whose business it is to decide on the form of instrument employed; but it should be remembered that any advance in the size of telescopes, refractors, or reflectors, over those at present in existence, must be considered to be to a certain extent, an experiment, and the nature of the difficulties which will be encountered can at present only be speculated upon, even by the most experienced; and therefore it behoves those whose province it is to decide on the matter to inquire diligently into the relative practicability of the various forms of telescopes in order that they may not decide on a form which might be, if ever accomplished, of great usefulness, but which on trial would be found to be, in the present state of art, impossible to manufacture.

"With respect to refractors, the first great difficulty to be met with is that of procuring suitable discs of glass. Of our glass manufacturers only two firms seem to possess the secret of manipulation of optical glass, viz., Messrs. Chance, Brothers and Company, of Birmingham, and M. Feil, of Paris, a descendant of the celebrated Guinand. Of these one at least speaks confidently of producing discs up to one metre in diameter; but when I consider the difficulty which I know was experienced in moulding the 27-inch discs for the Vienna objective I cannot say that I feel the same confidence. These 40-inch discs would require to be obtained in one single piece, just three times the quantity of homogeneous glass that the Vienna discs required, and though I am not of course in the secrets of the glass manufacturers, it appears to me that the chances of obtaining 40-inch discs in the present state of the art are remote.

---

[1] Continued from p. 183.

"The other difficulties of manufacture of refractors consist in the nicety of the operation connected with the calculations of the curves, the manipulation of such extremely costly material, and the enormous labour and trouble of the figuring and perfecting of the objective. All these, however, I have no doubt will be overcome by the optician for any size which the glass-maker is at all likely to produce.

"Now, as to the difficulties connected with the manufacture of reflectors, whether metallic or silver on glass.

"First, as to the difficulty of producing the metallic or glass disc to work upon.

"Lord Rosse has succeeded years since in casting, annealing, and perfecting discs of six feet in diameter, and any difficulties he met with were not such as to lead me to the belief that the limit of possible size has been by any means reached. As regards glass mirrors, the question has never been discussed, for in any sizes that have been made up to the present time, it was only necessary to go to the plate-glass manufacturers and say, 'I want a disc of crown glass of such a diameter and such a thickness,' and forthwith the glass disc was delivered without any trouble; but, when we come to these extraordinary sizes, it is quite a different matter. For the 4-foot disc of glass for the Paris reflector, in place of that which has so recently resulted in failure, the St. Gobain Glass Company require twelve months' time to perfect (although, be it remembered, the quality of the glass is here of no consequence whatever); and I have been myself in correspondence with the principal glass manufacturers here and on the Continent, and not one of them is willing to undertake even a 6-foot glass disc; so that it would appear that, above that size, the silver-on-glass mirrors are out of the question.

"This much, however, is to be said: If anyone were to go to a brass- or bell-founder's and ask them to undertake a speculum of six feet in diameter, he would almost certainly be met with a refusal; and yet Lord Rosse has proved the feasibility of it. And so, reasoning by analogy, might the manufacture of a six- or eight-foot glass mirror be possible, if undertaken in the same scientific spirit in which Lord Rosse undertook his. I answer to this—Yes; perfectly true; but this is too purely a speculative matter to be considered at the present day in the choice of telescopes.

"The other great difficulty in the manufacture of reflectors is the annealing of the disc, and I believe it is this difficulty which limits to so narrow an extent the production of glass discs for silver-on-glass mirrors."

We can abundantly gather from this paper of Mr. Grubb's that our opticians are doing all that lies in their power to give us increased power in the future. The fact that in the last few years one refractor of 25 inches, and two of 26 inches, have been acquired to science, leads us to hope that for the present progress will lie in increasing the dimensions of that instrument. Mr. Grubb, indeed, has already in hand one of 27 inches for the Austrian Government. The *contretemps* to the four-foot Foucault in Paris will also help to set the tide in the same direction.

From what has preceded it will be seen that each increase in the power of the telescope is of little avail unless we use it in purer and purer air. It is quite true that in the telescope much of the injury to definition arising from currents in the tube may be got rid of by the employment of lattice-work; but this, of course, will not lessen the atmospheric effects of the column of air ever increasing in diameter between the telescope and the object.

Prof. Piazzi Smyth's astronomical experiences on Teneriffe will still be in the minds of many of our readers. He showed that an enormous advantage was secured from observations so soon as half the atmosphere was below the observer. A more recent experiment by Dr. Draper, however, has shown that it will not do to go blindly and put the telescope on any high mountain. The conditions of each place from this single point of view must be carefully studied. Summing up his experiences of the Rocky Mountains up to heights of 10,000 feet, Dr. Draper says:—

"On the whole, it may be remarked of this mountain region that the astronomical conditions, especially for photographic researches, is unpromising. In only one place were steadiness and transparency combined, and only two nights out of fifteen at the best season of the year were exceptionally fine. The transparency was almost always much more marked than at the sea-level, but the tremulousness was as great or even greater than near New York. It is certain that during more than half the year no work of a delicate character could be done. . . . Apparently therefore, judging from present information, it would not be judicious to move a large telescope and physical observatory into these mountains with the hope of doing continuous work under the most favourable circumstances."

J. NORMAN LOCKYER

(*To be continued.*)

ELECTRICAL ANALOGIES WITH NATURAL PHENOMENA

WITHIN the last few years M. Gaston Planté has at intervals described a series of very curious phenomena produced by electric currents of high tension, and has pointed out numerous analogies which they present with several atmospheric and cosmical phenomena. Without committing ourselves to the belief that these analogies are real, the phenomena described are so interesting that we are glad to be able, by the kindness of M. Planté, to reproduce some illustrations of them.

To obtain electric currents of high tension M. Planté has employed secondary batteries of sheets of lead, which, as is known, constitute powerful accumulators of voltaic electricity. By associating a very great number of batteries uniting from 400 to 800 of these secondary couples, a discharge is obtained equivalent, according to M. Planté, to that of from 600 to 1,200 Bunsen couples arranged in tension.

Fig. 1 represents the arrangement of 400 secondary elements divided into ten batteries. This is the source of electricity employed for some of the earlier experiments which we are about to describe. The more recent ones have been made with 800 secondary elements arranged in twenty batteries of forty couples. A second series of batteries similar to the first is arranged in another room, and the current which it furnishes is joined to that of the first series by conducting wires suitably adjusted. These batteries, associated at first in simple circuit by means of commutators, do not require to be charged all at once like two Grove or Bunsen couples. When they have not been out of use for too long a time a few hours suffice to charge them. We may then, by turning the commutators, unite all the secondary elements in tension and use at will, either in a few seconds or in a longer time, the enormous quantity of electricity resulting from the chemical work accumulated during two hours by Grove or Bunsen batteries.

Such was the powerful means adopted by M. Planté in making his late experiments. In his earlier experiments he used a much simpler apparatus.

The gyratory movements accompanied with luminous effects which M. Planté had observed with a powerful current of electricity, and the spherical and annular forms manifested by bodies submitted to that action, suggested to M. Planté the probability of the electric origin of the forms of some of the nebulous masses of matter which are not resolvable, and particularly of those which assume a spiral form.

He describes an experiment in which a cloud of metallic matter attracted to an electrode by the electric current assumes in the centre of the liquid a gyratory spiral movement under the influence of a magnet[1] A glance at Figs. 2, 3, and 4, which represent this experiment, is sufficient to enable us to recognise their similarity to the forms of spiral nebulæ described by Lord Rosse. Some of these have the curvature of their spirals tending in a direction opposite to that of the hands of a watch, like those in Fig. 3, such as in the nebula in Berenice's Hair; others have their spirals in the same direction as the hands of a watch, like that of Fig. 4, as in the nebula in Canes Venatici. M. Planté is inclined to believe that, in presence of an analogy so striking, we are authorised to think that the nucleus of these nebulæ may be constituted by a true centre of electricity; that their spiral form may be determined by the near presence of celestial bodies strongly magnetic, and that the direction of curvature of the spirals may depend on the nature of the magnetic pole turned towards the nebula. He

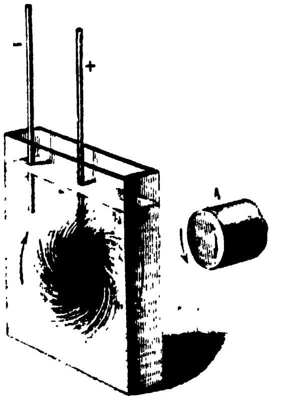

Fig. 4.

Fig. 2.—Cloud of metallic oxide formed in a voltameter before the approach of a magnet. Figs. 3 and 4.—Gyratory movement communicated to the cloud of metallic matter by the action of a magnet.

---

[1] It is easy to reproduce this experiment and even throw the effect on a screen, by means of an electric current equivalent to that of fifteen Bunsen elements. The electrodes are copper wires; the liquid is acidulated with 1-10th of sulphuric acid From the extremity of the positive wire escapes, with a slight hissing sound, a thick cloud of the protoxide of copper or of finely-divided copper, and this wire takes the form of a very sharp point. The arrows around the spirals in the figures indicate the gyratory movement which this cloud assumes under the influence of a magnet; and the arrows around the magnet represent the direction of the electro-magnetic currents; B is the north end A the south pole.

suggests that if we had powerful enough telescopes, the neighbourhood of the nebulæ should be searched to discover stars capable of exercising such a magnetic influence. If such a star was found likely to act thus on any nebula, then the line passing through the centre of the nebula and the star should be searched to discover if, at the other magnetic pole of the star, a second nebula did not exist, with its spirals in a contrary direction to those of the former.

M. Planté states that with a much more intense source of electricity he has observed small luminous rings, composed of incandescent particles, altogether detached from the electrode. These rings, the centre of which was agitated by a small liquid whirlpool, moved in the interval comprised between the electrode and a very large luminous ring formed round about by the shock of the electric current against the sides of the voltameter.

FIG. 5.—Luminous globule formed at the surface of a liquid by an electric current of high tension.

The Formation of Hail.—In a paper in the *Comptes Rendus*, t. lxxxi. p. 616, M. Planté had shown the influence which atmospheric electricity in a state of discharge must have in the formation of hail, not by producing the cold necessary to congelation, as is sometimes supposed, but by exercising, on the contrary, a powerful heating action, capable of rapidly vaporising the moisture, and of projecting the vapour into the cold regions of the atmosphere. To succeed in explaining the part played by electricity in this natural phenomenon, it is necessary to point out the mechanical action which may result from the passage of the electric fluid into the midst of aqueous masses, and thus to project into the air liquid globules susceptible of being transformed into hailstones.

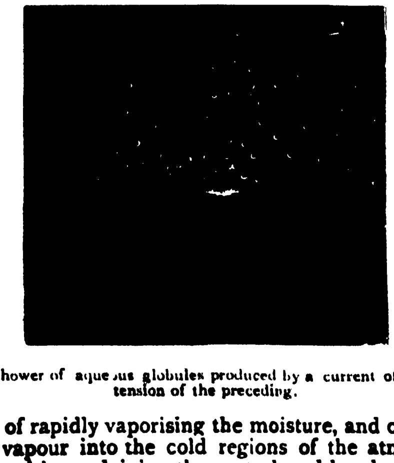

FIG. 6.—Shower of aqueous globules produced by a current of double the tension of the preceding.

In previous experiments M. Planté showed that with an intense source of voltaic electricity, the immersion of the positive wire in a conducting liquid, such as salt water, determines the aggregation of aqueous molecules around the electrode in the form of a luminous spheroid, in consequence of a double simultaneous effect of flow and aspiration, or of passage in two directions which seems peculiar to the electric current (Fig. 5).

But by employing a current still more intense, resulting from the discharge of a battery of 400 secondary couples, he obtains, by the immersion of the positive wire, instead of a single globule, a shower of innumerable ovoid globules, which succeed each other with excessive rapidity, and are projected to more than a metre distance from the vessel in which the experiment is made. The spark produced at the same time at the surface of the liquid presents the form of a corona or aureole of many points, from which burst forth the aqueous globules (Fig. 6).

The metallic property of the electrode is not necessary to obtain this effect. A fragment of filter paper, moistened with salt water, in communication with the positive pole, also produces the phenomenon, and constitutes a humid mass analogous, to a certain point, with that of a cloud from which proceeds an electric current. If, instead of encountering a deep layer of liquid, the current meets with a moist surface such as the sides or the inclined bottom of a basin, the heating effects predominate, the aureole is very brilliant, and the water is rapidly transformed into vapour (Fig. 7).

The action of the current then differs according to the resistance which is opposed to it, and we find here a new example of the reciprocal substitution of heat and mechanical work resulting from the electric shock. When the work represented by the violent projection of the liquid appears, there is neither heat nor vapour developed, and when no visible work is accomplished, when the liquid is not projected, heat is engendered and vapour disengaged.

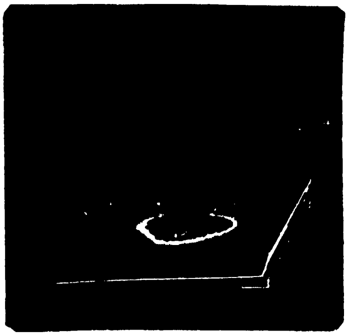

FIG. 7.—Jets of vapour and luminous streaks produced by an electric current of high tension on meeting with a moist surface.

M. Planté sums up the results of these experiments thus:—

1. Electric discharges produced in the midst of clouds may, according to the greater or less density of these moist conductors, determine their reduction into vapour, or their instantaneous aggregation into globules of a volume much greater than that of the globules of the cloud, and the liquid bombs thus formed may be projected to great heights, where the temperature is notably lower than that of the medium in which the discharges are produced.

2. The formation of hailstones, in the case where they do not present a series of opaque and transparent layers, but a structure radiating from the centre, is also explained by such a mechanical action; they must be produced by a single jet, and congealed under the same volume which they had at the moment when they were shot forth by the electric current.

3. The ovoid or pyramidal form of these hailstones, as also their angular parts, aspirates or protuberances, are due to their electric origin.

4. The gleam sometimes emitted by hailstones is due also to electricity; for although in the experiments described, it could not be distinguished whether the globules were self-luminous or shone by the reflection of the spark, it is probable that they were also rendered phosphorescent by the electric current which they contained.

M. Planté admits the action of other agents, such as wind currents, in the formation of hail, but only as accessories to the action of electricity. They are concurrent causes which only prepare the conditions favourable to its production, while electricity is the efficient cause which, by its very presence in the clouds and by the instantaneous power of its discharges, determines the sudden formation and the fall of the meteor.

M. Planté is still prosecuting his researches on this subject.

(*To be continued.*)

ENTOMOLOGY IN AMERICA

THE U.S. Entomological Commission which was organised and placed under the auspices of Prof. Hayden's Geological Survey for the purpose of investigating and reporting the entire subject of insect ravages throughout the western regions of our continent, have completed their field labour for the present season.

The members of the Commission have been busily engaged in the preparation of the several parts of their Annual Report, and will soon meet in Washington, where they will have a protracted sitting to get everything ready for the printer. This report is looked for with much interest by the farmers of the west, and the character of the commissioners is a guarantee that it will be creditable from the scientific, and valuable from the practical, standpoint. The Report will contain sixteen chapters, under the following heads:--Introduction, Riley; Chronological History, Packard; Statistics of Losses, Thomas; Classification and Nomenclature, Thomas; Geographical Distribution, Thomas and Packard; Migration and Meteorology, Packard and Thomas; Original Permanent Breeding Grounds, Riley, Packard, and Thomas; Habits and Natural History, Riley; Embryology, Packard; Metamorphoses, Riley and Packard; Invertebrate Enemies, Riley; Vertebrate Enemies, Thomas; Remedies and Devices for Destruction, Riley; Prairie Fires *versus* Locust Injury, Riley; Agricultural Bearings of the Subject, Thomas; Ravages of other Locusts, Packard and Riley; Locust Ravages in other Countries.

These chapters will embrace many sub-chapters, and the Report will be as exhaustive as the limited time for its preparation will permit.

In Chapter IV. the western extension and the northern and eastern limit of the species' range are fully given.

In Chapter V. the laws governing its migrations are for the first time defined. A very large number of data have been collected in reference to the subjects of this chapter. Not only are the general laws governing the movements of the insect now defined, showing a regular migration southward and return migration northward, which may be counted on and foreseen; but many important and highly interesting facts in reference to their local flights are brought to light, which will henceforward form a part of the history of the insect.

In Chapter VII. several other laws governing the species are also adduced; and the importance of the discovery of the laws which regulate the doings and movements of the pest, cannot be over-estimated. In said Chapter VII. many new facts will for the first time appear, and all that is definite and accurate be made known.

In Chapter X. many new discoveries will be recorded, some of them of great scientific interest and importance. Of these may be mentioned the transformation of the silky mite (*Trombidium sericeum*). This is an eight-legged creature, which preys on the locust eggs. It is proved to be the mature form of the little six-legged mite (*Astoma gryllaria*) which is parasitic on the locust. Insects described under different genera are thus proved to be specifically identical. The life-history of the blister-beetles will also be given, their larvæ feeding upon locust eggs, and undergoing singular changes called hypermetamorphoses. The interest attaching to this discovery among entomologists, as well as among farmers, is best appreciated when it is considered that absolutely nothing has heretofore been known of the larval habits of these blister-beetles, notwithstanding the fact that for half a century much attention has been given to the subject by scientific men, on account of the commercial value of Cantharis, or Spanish fly, and of the great injury to potatoes and other plants committed by several of our American species.

In Chapter XI. are given the locust feeding habits of many western animals not heretofore known to have that habit, and the good offices of birds are especially made manifest, examinations of the stomachs of over ninety species and 630 specimens having been made with special reference to their locust-eating habits. The record in reference to these examinations is very full, giving the dates, the locality, the common and scientific names of the species, and the number of locusts and other insects found in each. The value heretofore placed on these aids by entomologists is fully sustained by this record.

In Chapter XII., which will be one of the most extended and most important practically, it is clearly shown that the young locusts may be controlled, and by what means; while the way is pointed out how to better control the winged insects. Many valuable devices for destruction will be illustrated, among them one invented by Prof. Riley, which gave great satisfaction, and will, it is believed, supersede all others as a cheap and practicable remedy applicable at any season, whether the plants or the insects be small or large.

In Chapters II. and IV. are given statistics showing the immense losses inflicted on western agriculturists by the locust. These chapters also show what crops are most liable to injury and what are most easily protected; also the best methods of cropping in order to reduce the injury to a minimum. A chemical analysis of the dead locusts has been made, and is unusually interesting. The insects furnish a new oil, which will be christened Coloptine, and a very large per-centage of pure formic acid. Though this acid exists in the ant and some other insects, it is with difficulty obtained in large quantities, whereas by the action of sulphuric acid upon the locust juices it passes off with great readiness and in remarkable quantity and gravity. The various uses of this acid whether as a therapeutic agent or as laboratory re-agents, &c., are capable of great and valuable extension when it can once be obtained so readily and in such quantity.

The Report is expected to make about 500 pages, and will, it is hoped, be published in February or March. Although the Commissioners have divided the labour among them, the Report will form one complete whole, as the work of each will be discussed and revised by the Commission as a whole.

The Annual Report, which is intended more particularly for the practical farming public, will be followed by memoirs of a more purely scientific nature—one by Dr. Packard on Anatomy and Embryology; one by Prof. Riley on the Natural History of other Locusts, and one by Prof. Thomas on the classification of the *Acrididæ*.

While it has been the object of the Commission to cover as much ground as possible so as to make the Annual Report as full and valuable as the time would permit, there yet remain several important subjects that it has so far been impossible to properly and exhaustively study. The territory affected is so vast, embracing over a million square miles, that much of it was imperfectly explored, especially in the north-west. Mr. Riley had to cut short his investigations in British America both for want of time and want of funds. For similar reasons, and on account of Indian troubles, Montana, Wyoming, and Dakota, have been but superficially explored.

The year 1877 was an abnormal year, *i.e.* the insect had, the previous year, overrun a large section of country in which it is not indigenous, hatched in such country in the spring. This was most fortunate for many reasons, as it enabled the Commission to carefully study the insects in this their unnatural condition, and to carry on experiments with a view of learning how to control them. Much of the work of the Commission was with these young insects. The losses sustained through the devastation of the pest by young and struggling frontier populations, ill able to bear them, were immense; and there was so much discouragement that hundreds and thousands of persons were on the point of abandoning their new homes last spring. At this juncture the Commission went into the field, and by its encouraging predictions (which were all verified) and recommendations, imbued the people with hope and confidence, and drew westward again the emigration that had almost stopped. All this work, however, interfered with needed investigations into the proper range, the native home and breeding grounds, the source of swarms, and many other important questions which can only be properly studied during a normal year. It is, therefore, very important that the investigations be continued until every question is settled that human investigation can settle.

For the proper settlement of some of the questions the co-operation of the Dominion Government is desirable, and has been promised by the Canadian authorities if the work of the Commission should continue.

It will be unwise to stop the work of the Commission before completed. The work should be made so thorough as to obviate any necessity in future years of creating another commission for the same purpose. After careful estimates it is concluded that the work can be satisfactorily completed only with two more years' investigation and experiment. The Commission therefore ask for a continuance of the appropriation of 25,000 dols. asked for a year ago.

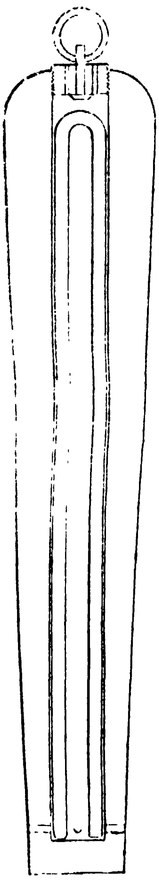
There are various other injurious insects of national importance, of which much has yet to be learned, and in addition to completing the locust investigation, the Commission contemplate, during the coming two years, studying and reporting on some of these worst enemies to American agriculture. They are especially desirous of reporting on the cotton-worm of the south, which, though often so disastrous to the cotton crop, has never been fully studied, and in the mere natural history of which there are yet many mysteries and conflicting theories.

Much has yet to be done in giving practical form to the conclusions arrived at and plans proposed by the Commission to enable the work already done to bear proper fruit. To bring about the needed co-operation of the two Governments, to cause proper laws to be enacted in all the states interested, and to enforce the truths that alone will make man master of the situation, is largely the work of the future.

SOUNDING APPARATUS

THAT Sir William Thomson's recent application of the pianoforte wire to sounding in small depths for the ordinary purposes of navigation is of great value, will be admitted readily by those who are familiar with the present process. But it occurs to me that a formidable objection to its general introduction into naval or mercantile vessels is to be found in the necessity of using chemically-prepared tubes for determining the depth of water. Sir William's latest device is (I believe) a straight glass tube two feet long, open at one end and inclosed in a brass tube attached above the sinker, in which air is compressed by the pressure of the water, the amount of compression being determined by the height to which the water rises in the tube. This height is marked by the decolorisation of a coating of chromate of silver on the inside of the tube, effected by the sea-water. A number of such tubes, properly prepared, must therefore be kept at hand, and when once used they must be coated anew, an operation of no little difficulty.

I have suggested a form of sinker in which these objections are obviated, while the principle is retained. The sinker is of iron three inches in diameter at the bottom, five inches at the top, and 26·5 inches long. It is cast with a cylindrical cavity, two inches in diameter, extending from the top to within an inch of its base. This cavity contains the glass tube by which the depth is determined. A tube about forty-eight inches long is taken, closed at one end and bent back on itself at its middle point, so as to make two legs each twenty-four inches in length. This is placed inside the sinker (the bend upward) and a screw tap, carrying a swivel-link for the sounding line, is screwed over it. Holes in the bottom of the sinker and through the screw tap allow the water access to the tube. As the sinker descends, in sounding, the air within the tube is compressed and the water rises in the open leg. When the column of water reaches the highest point of the bend, the pressure then corresponding to a depth of about five and a half fathoms, any further descent of the sinker will cause the water to pass over into the lower end of the closed leg. The compression of the air will then take place in the *upper part of the closed leg*, the maximum compression being indicated by the length of the column of water remaining in that leg when the sinker is lifted again to the surface. As the sinker is being raised, the air, expanding under the diminished pressure, drives the water out of the open leg. The inside and outside pressures are therefore equal at any instant. The tube may be graduated in inches and tenths, and a table will give the depth from the reading of the tube. The tube is then easily emptied and is ready for another cast. The form of the sinker is such that the bend of the tube is kept at a higher level than the open end in case the sinker should fall over when it reaches the bottom—the entrance of surplus water is thus prevented. An ordinary cup attachment for a bottom specimen can be applied to the end of the sinker.



The tube described will not indicate a depth less than five and a half fathoms. If it is desired to obtain casts in shoaler water a tube with the open leg shorter than the closed leg may be used. One in which the length of the open leg is one-fourth that of the closed leg will indicate depths of two fathoms and upwards.

I am aware that Sir Wm. Thomson has a tube for bringing up the column of water, but it requires the use of valves, which can never be kept tight under such enormous pressures as those to which the sounding-tubes are exposed.

I inclose a sectional drawing of the above-described tube and sinker.

THEO. F. JEWELL, Lieut.-Com. U.S. Navy

OUR ASTRONOMICAL COLUMN

THE VARIABLE STAR R AQUARII.—Harding notified his discovery of variability in this star in 1811, in the first volume of the *Zeitschrift für Astronomie*. The earliest attempt to determine the period appears to be that of Westphal, in the *Zeitschrift für Astronomie*, vol. iv. p. 218; he used Harding's observations between October 20, 1811, and January 19, 1817, which, though not numerous, sufficed to give an approximate value, while they also indicated that the star at times was as bright as 6·7 m., and at others was invisible in Harding's telescope. Westphal's period is 382·5 days. Although the variability of the star has thus been long known, it would seem that few of these objects have been less observed, and it may be recommended to the attention of those who are interested in this branch of astronomy, and whose positions enable them best to command a star at 16° south declination. In vol. vii. of the Bonn observations, Argelander deduces the following formula for the maxima:—

1843, September 4·7 + 388^{d}·011 E.,

which is adopted in Prof. Schönfeld's second catalogue (Manheim, 1875); the maximum of the present year would therefore fall on September 25, and may be well observed. In the same catalogue the degree of brightness at minimum is set down as "11 m (?)." Harding estimated the star 6·7 m. on October 20, 1811, and on January 24, 1812, it was not visible in his telescope, being then below what he called a tenth magnitude, so that observations for determination of the minima should probably be commenced not later than seventy days after the maxima, but it is hardly necessary to remark that in the actual state of our knowledge of the variations of this star, continuous observations through as long a period as its position allows, will possess much interest. The best determination of the place of R Aquarii will be that of the Greenwich Catalogue of 1864, giving for the beginning of the present year—

R.A. 23h. 37m. 30s·35, N.P.D. 105° 57′ 37″·3.

ϵ INDI.—When may we hope that some southern observer will find opportunity of attacking the parallax of this remarkable star, the large proper motion of which was first pointed out by the late Prof. D'Arrest, and confirmed by Moesta from the Santiago observations of 1856? Mr. Gill, who allows nothing to escape him, during his brief visit to the other hemisphere, wherein Lord Lindsay's heliometer enables him to do an astronomical service, states that he has measured the distance and position-angle of ϵ Indi relative to five surrounding stars, and hopes "that this may serve as the foundation at some future day of a determination of its parallax and proper motion," but it is obvious that the shortness of his stay at Ascension does not permit of an attempt to measure the amount of parallax—a very interesting undertaking in the case of this star, which, had time allowed, we do not think that Mr. Gill would have hesitated to attempt. And ϵ Indi is not the only star which holds out prospect of success in parallax investigations in the southern hemisphere.

THE SATELLITES OF MARS.—In the last number of the "Monthly Notices of the Royal Astronomical Society" is a communication from the director of the Observatory at Melbourne, giving the results of a search made for the satellites of Mars, in consequence of a telegram notifying their discovery, and received from Sir George Airy on August 22. At that time, from an accident to the declination movement, the large reflector was not available, but observations with it were commenced on September 26. Mr. Ellery states his search to have been fruitless, except that on one occasion it was believed that one of the satellites was seen. This was on the night of October 16, when Mars having occulted a star of the thirteenth magnitude at 22h. 15m. sidereal time, after its emergence a very faint point was seen half a diameter from Mars s.p.; "this was watched for nearly an hour, when its position indicated a motion with Mars," but the sky becoming cloudy, no measures could be made, and, it is added, "no other signs of satellites have been observed since."

If we use the elements of the exterior satellite employed for the ephemerides which have appeared in this column, and which agree precisely with measures of position-angle made by Mr. A. Common, of Ealing, with his eighteen-inch silver-on glass reflector on the date in question (October 16), we have the following angles and distances:—

Melbourne Sidereal Time		Position.		Distance.		Distance from Limb.
h. m		°		″		″
22 15	...	216·0	...	34·6	...	25·2
23 15	...	196·7	...	27·1	...	17·7
0 15	...	167·6	...	23·5	...	14·1

Therefore, although the satellite would be in the south-preceding quadrant up to about 23h. 45m. sidereal, its distance would be greater than that estimated at Melbourne, and it is doubtful if this satellite was seen.

As regards the inner satellite, it is not practicable from the measures hitherto published to form so close an estimate of the positions as late as October 16, but on calculation from elements which represent sufficiently well the measures to September 20, it would appear that the satellite was in the south-preceding quadrant after about 23h. 30m. sidereal time, and its distance from the limb at that time would be approximately a semi-diameter of the planet. Thus if either satellite were really observed, it was most probably the interior one—which, indeed, we are assured, is intrinsically the brightest. But the want of better success with the great Melbourne reflector would rather imply that however well adapted for delineation of nebulæ and similar purposes, the instrument fails with observations of such objects as the satellites of Mars.

NOTES

WE understand that on the representation of the Professors of the Royal School of Mines and of the Director-General of the Geological Survey as to the want of proper accommodation for geological teaching in the School of Mines in Jermyn Street, the Lords of the Committee of Council on Education have transferred the instruction in that subject to the Science Schools at South Kensington. As Prof. Judd is supplied with a complete collection of specimens for teaching purposes, and as a laboratory is now provided for him, he will be in a position to give that practical instruction which it is so desirable should be within the reach of geological students.

STUDENTS of pleistocene geology will be gratified to learn that the well-known very fine collection of Ilford fossils, formed by the late Dr. Richard Payne Cotton, F.G.S., has been bequeathed to the Museum of Practical Geology, Jermyn Street. The collection contains 246 specimens of vertebrate remains, consisting of bones belonging to species of mammoth, rhinoceros, ox, aurochs, hippopotamus, horse, deer, Irish elk, lion, bear, beaver, water-rat, wolf, and several kinds of birds. A very perfect lower jaw of the beaver (*Castor europæus*), with some well-preserved bones of the *Elephas primigenius*, the *Rhinoceros leptorhinus*, and the *Bos primigenius*, are among the gems of this private collection, which will form a welcome and most valuable addition to the contents of the National Museum of British Fossils—the more so as the series of late tertiary vertebrates in that collection is by no means so large and complete as could be desired. Every one interested in the geology of the metropolitan area is aware that the Cotton collection, together with that made by Sir Antonio Brady, which has lately been acquired by the British Museum, have formed the basis of those interesting researches which have been carried on by several distinguished palæontologists concerning the nature of the vertebrate fauna which inhabited the Thames valley during post-pliocene times. The nation is very fortunate in thus having secured for the use of students in the future both of these remarkably fine collections.

IT is with much regret that we have to record the death, on the 10th inst., of Andrew Murray, F.L.S., the eminent entomologist. In the field of scientific botany and forestry and in aid of our scientific intercourse with foreign countries he has done good service, and in his own special line as a practical entomologist, the Government collection at Bethnal Green stands as a monument of patient labour, as well as profound knowledge of his subject. A keen observer and unflinchingly truthful, the records of his original observations, or his careful compilations, given in his peculiarly terse and condensed style are a valuable legacy. A valued naturalist and assiduous worker he continued at his post till within a few days of his decease, and sunk away quietly and gently after some months of failing health. In private life he was greatly esteemed as a true-hearted friend, unwearied in aiding wherever he could be of assistance, and also for his high intellectual powers.

THE death is announced, on the 7th inst., of Prof. William Stokes, M.D., F.R.S., of Dublin.

ONE of the oldest, best known, and most useful of American naturalists, Dr. J. P. Kirtland, died on December 10. In 1848 Dr. Kirtland received the appointment of zoologist to the Geological Survey of Ohio, the duties of which he discharged with great fidelity, and his publications connected therewith constitute in a measure the bases of subsequent similar investigations in the West. His most prominent work was that in connection with the fishes of Ohio, for the accurate knowledge of which he laid the foundation, establishing and identifying many of the species of Rafinesque, which up to that time had been considered entirely mythical. He described many new species of western fishes, and the discovery of one species of bird of Ohio is due to his zeal.

AT a meeting held last week in Sheffield, a resolution was unanimously passed to invite the British Association to visit that town next year. Committees were appointed, and it was decided to raise a guarantee fund of 2,500*l*.

DR. SCHLIEMANN has been elected an honorary member of the Deutsche anthropologische Gesellschaft. The diploma of membership is a handsome specimen of artistic work, being encircled by allegorical representations of the excavations at Troy and Mycenæ, and bears the signatures of Virchow, Kollmann, Fraas, Schaafhausen, and Weismann.

THE new New York Natural History Museum was opened by President Hayes on the 22nd ult. The museum is in Manhattan Square, on a plot of land opposite Central Park, and the plan of the entire structure contemplates a colossal enterprise, which cannot be completed within the present century. It consists of buildings arranged in a parallelogram, of 850 by 650 feet, and of two lines of buildings which divide the interior space at right angles, thus forming four equal courts. At the centre of each side of the parallelogram, and at its four angles, lofty towers will be erected. At the intersection of the cross in the centre of the parallelogram, a dome is designed to cover a space of 120 feet diameter. The portion of this great structure which is now completed is a four-story building with a double attic; it has a length of 200 feet; it will form the southern one of the arms of the interior cross. The walls are three feet thick at the top. The whole building is of brick, and is regarded as strictly fireproof. The city has appropriated $700,000 for it, besides giving the land.

MR. STANLEY will probably arrive in England this week. He has been received with enthusiasm at Rome, Marseilles, and Paris. The Chamber of Commerce and the Geographical Society of Marseilles presented Mr. Stanley with medals. No doubt our own Geographical Society will take the lead in the warm reception which will certainly be accorded in this country to one of the foremost of explorers.

THE Commission for reorganising the Observatory of Paris has ended its sittings, as we have already reported. The commissioners recommend no change in the present organisation of the International Meteorological Office; but, taking into consideration the actual wants of meteorology, it has advised the Minister of Public Instruction to appoint a Meteorological Commission, in order to suggest any measures which might be likely to promote the interests of meteorology at large, without interfering with the working of telegraphic weather forecasts sent by the International Office to the sea-ports and more than 1,200 parishes all over France.

THE Scientific Association of France, created by M. Leverrier, after having elected M. Milne-Edwards for its president, has decided upon organising a series of lectures at the Sorbonne, to describe important new inventions and discoveries. The first meeting will soon take place, when M. Cailletet's experiments will be exhibited and explained by M. Henri St Claire Deville. M. Dumas will also deliver an address summarising the history of the Association and reviewing the services rendered by it to science. It is stated that M. Dumas will propose to the Association to initiate a subscription for erecting a monument to the great astronomer who founded it.

IN several cities of Holland committees have been formed with a view to collect subscriptions to defray the expenses of the proposed expedition to the Arctic regions, to which we referred some time since.

MACMILLAN and Co. are about to publish "A Monograph on the Development of Elasmobranch Fishes," by Mr. F. M. Balfour, M.A., Fellow and Lecturer of Trinity College, Cambridge. The work is divided into twelve chapters, and contains the results of much original research on the part of the author, who, on certain points, as on the spinal and cranial nerves, advances views which are a modification of those previously accepted.

IT is announced that the *American Naturalist*, which has had so long and useful a career in Salem and Boston, will hereafter be published in Philadelphia by Messrs. M'Calla and Stavely, under the editorship of Dr. A. S. Packard and Prof. E. D. Cope.

REPORTS from the Island of Sylt, on the west coast of Schleswig-Holstein, state that the storm-flood, which caused such serious damage along the Continental shores of the German Ocean last autumn, has laid bare some remains of the village of Eidum, which perished in the year 1436 by the sea suddenly breaking over it and covering it up. Stone foundations of former dwellings, garden-walls, and wooden remains of various kinds are now seen there, also numerous well-openings, built of massive pieces of dried and baked peat. It is also stated that numerous old coins and utensils have been found there, as well as a well-preserved, carved, and engraved metal bracelet.

RECENT excavations made at Trèves, in the so-called Roman imperial palace, have yielded rich results in Roman antiquities.

ON December 26, at 8 A.M., two meteorolites fell near the village of Höhr (in the Prussian province of Hessen Nassau), close to the high road leading from Neuwied to Coblenz. It is stated that the noise caused by the fall was very characteristic.

THREE earthquakes were observed at Kirlibaba, in the Bukowina, on December 28 and 30 respectively. A fourth phenomenon of this nature was felt at Innsbruck, in the Tyrol, on the 3rd inst., at 8 46 P.M.

BERLIN is listening to an interesting series of lectures delivered under the auspices of the Society for African Exploration. On the programme we notice Dr. Nachtigal, "Ancient Darfour;" Dr. Güssfeldt, "The Arabian Desert;" Dr. Hildebrandt, "Pictures from Equatorial Africa," Prof. Hartmann; "Fauna of the Swedish Islands," &c.

THE two African Societies at Berlin, which have hitherto existed independently of one another, have now finally resolved to unite into a single society.

WE have received the first number of *The Midland Naturalist*, the journal of the associated societies and clubs of the Midland counties, the union of which we referred to some time since. It is a neat and well-printed journal, containing seven good papers, besides miscellaneous matter. Besides the opening address, explaining the formation and objects of the Union, there are papers on abnormal ferns, by Mr. E. J. Lowe, F.R.S.; on an improved aneroid, by Mr. W. J. Harrison, F.G.S.; on the marine zoology of Arran, by Mr. W. J. Hughes (giving the results of an excursion by the Birmingham Natural History Society last summer); Lepidoptera in the Midland Counties, by the Rev. C. F. Thornewill; Entomostraca, by Mr. Edwin Smith; and a paper on some new features in the geology of East Nottingham, by Mr. J. Shipman. This is a very good start, and we hope *The Midland Naturalist* will fill a useful place in our scientific literature. Hardwicke and Bogue are the London publishers.

REPORTS from the Bernese Alps state that the amount of snow fallen during the present month is much greater than has been experienced for a number of years.

THE wolves in Eastern France have become unusually bold during this winter, and reports are constantly received of their depredations in various parts of the country. In one instance a letter-carrier was driven back by them from his regular route.

AN interesting experiment was lately carried out in the neighbourhood of Emmendingen, on the River Danube, to show its subterranean connection with the valley of the Rhine. The river is separated here by a range of Jura limestone from the district drained by the Rhine, and it has long been suspected that the Aach, which has its source in this range and flows into Lake Constance, was really supplied by the Danube. In order to solve the problem, recourse was had to fluorescin, the phthalein of resorcin, a compound which yields with alkalies magnificent green fluorescent solutions capable of imparting this property to enormous masses of water. A solution of this substance was introduced into the Rhine at Emmendingen, and two and a half days later the bright green fluorescence was visible in the Aach, the source of which is about five miles distant, and lasted for thirty-six hours. This experiment shows most decisively that the Upper Danube shares its water between the Black Sea and the North Sea, and affords a most interesting explanation of the close similarity in the finny inhabitants of the two great European rivers.

WE notice the appearance, in Paris, of a French translation of the "Organic Chemistry" of Prof. Fittig, of Strassburg. This work, which in its present form is the tenth edition of the textbook originally issued by Prof. Wöhler, has long been a favourite with the German chemist on account of the scrupulous care and fidelity which have been exercised in preparing each successive edition. An English translation was prepared a short time since by Prof. Remsen, of Johns Hopkins University, formerly one of Fittig's assistants, the circulation of which is confined, however, chiefly to America.

ARRANGEMENTS are being made for the holding of an International Exhibition at Sydney in 1879, under the auspices of the Agricultural Society of New South Wales. It is anticipated that many of the articles shown at the coming Paris Exhibition will be trans-shipped to Sydney.

A propos of the remarkable relation established by Dr. Kerr, a short time ago, between light and electricity, an interesting experiment has been made by Mr. J. Mackenzie, in Berlin, at the instance of Prof. Helmholtz (*Pogg. Ann.*, No. 11). A glass plate, 161 mm. long, 12 mm. thick, and with tin foil on its opposite sides, from which proceeded copper wires to a Ruhmkorff coil (with six Bunsen elements), or a Holtz machine, and to earth, was supported and covered with larger glass plates, and placed between two Nicols, as in Dr. Kerr's experiment, the light-source being a lamp. The electric action gave no perceptible increase of brightness, nor was any such obtained when polarised sunlight was used to give greater sensibility, and a leaf of mica thick enough to give the violet colour was interposed between the glass plate and the analyser. Experiments with oil of turpentine likewise gave negative results. (The high sensibility of the polariscope is demonstrated by distinct experiments.) It is therefore concluded that the phenomenon observed by Dr. Kerr is not produced by electric tension itself, but possibly in a secondary manner, through the heating thus caused. Confirmation of this is found in the fact that in Dr. Kerr's experiments it was only after about thirty seconds from closure of the circuit that the action reached its maximum; it also disappeared slowly.

IN a paper in the *Bulletin* of the Belgian Academy of Sciences (Nos. 9 and 10), Prof. Van der Mensbrugghe discusses the causes of the seemingly spontaneous movements of bubbles of air in levels and of vaporous bubbles in the microscopical cavities of minerals, these researches being part of those into the tension of surfaces of liquids. Prof. Mensbrugghe explains these movements, as Mr. Hartley also does, by changes of tension in the surfaces of liquids produced by changes of temperature; when the temperature of the liquid at one end of the bulb becomes, for some reason, higher or lower than at the other end, however small the difference, the tension of the surface decreases at the warmer end, and the bubble moves towards it. But, a thin film of water remaining on the glass, the surface of the liquid is enlarged at the warmer end, and diminished at the opposite end, and this, according to experiments of the author, lowers the temperature and increases the tension at that end; so that if the temperature now ceases to rise the motion of the bubble is not only stopped, but the bubble also returns backwards. Thus each displacement of the bubble immediately gives rise to such forces as tend to produce a motion in an opposite direction; and the variations of tension produce the more obvious motions the smaller the masses of liquid in which the bubble is swimming. The same explanation may be applied also to the movements of bubbles in microscopical cavities of minerals filled with liquids. In that case, the bubble being produced by the vapours of the liquid, its movements are yet more rapid, as every change of temperature is followed by further evaporation of the liquid, or by condensation, both which alter the dimensions of the surfaces of the liquid and their tension. The author supposes also that the Brownian motions of powders suspended in liquids may be explained in the same way, and that those powders which absorb most gas will best display this kind of motion.

PROF. EMILIO CORNALIA, an eminent naturalist and Director of the Museum of Natural History at Milan, has been decorated by the Emperor of Russia with the order of St. Ann for his efficient co-operation in the foundation of the institute for "Bachicoltura" at Moscow and Tashkend.

THE scientific expedition to Lake Lob-Nor, sent out by the St. Petersburg Geographical Society, under command of Col. Prjewalski, and to which we have already referred, has yielded most interesting results in every direction and is of particular importance with regard to the exploration of Kashgar. The new details obtained in reference to Lake Lob-Nor are remarkable. The expedition continued its way from Korla, following the course of the Tarim River down to its confluence with the Rokala Darja. On their way to the Lob-Nor the travellers passed the ruins of three cities. Lake Lob-Nor is of a marshy nature; its length is some 100 kilometres, by only 20 kilometres breadth. Col. Prjewalski explored the western and southern shores, and through the current of the Tarim River reached the middle of the lake. There the shallowness of the water and impenetrable vegetation prevented further progress; almost the whole surface of the lake is thickly covered with reedy vegetation. The inhabitants of the Kara Kurchintz district, on the shores of Lake Lob-Nor, are on the lowest step of civilisation. They live along the shores as well as on islands in the lake, in miserable huts constructed of reeds and branches twisted together. The whole of their possessions are their clothes, which barely cover their nakedness and are made of the fibres of a kind of lake weed, their nets, and their canoes, which are hollow trunks of trees. Metal objects, such as knives, hatchets, &c., are extremely rare among them. Col. Prjewalski, besides his ethnographical results, has collected rich materials for ornithological investigations. He reports that it is impossible to conceive the enormous number of migratory birds which, on their journey from southern countries to the north, or *vice versâ*, select Lake Lob-Nor as a halting place. At present the Russian traveller has wended his way southward and is engaged in the exploration of Tibet.

IN an interesting paper, published by M. Ph. Plantamour in the December number of the *Archives des Sciences Physiques et Naturelles* (Geneva), regarding the earthquake experienced in the immediate neighbourhood of the Lake of Geneva on October 8 last, the author proves most conclusively that the phenomena known under the name of "Seiches," and consisting in occasional and sudden alterations in the level of the lake, have nothing whatever to do with upheavals or depressions in the bed of the lake. During the earthquake referred to, not the least movement of the surface was perceptible, and had an alteration of only one millimetre taken place in the level, the instruments employed by MM. Plantamour and Forel, which continually register these alterations, would have most certainly shown them. The explanation of these "Seiches," therefore, is still a matter of considerable uncertainty, and it even remains to be seen whether barometrical pressure has any influence upon them or not.

Two enterprising men in Paris, a merchant and a doctor of medicine, whose names will be surely blessed by future generations, have made the valuable discovery that the different elements contained in sea-water are infallible preservatives against all possible diseases, and at the same time are never-failing remedies against existing illnesses. These two philanthropists have therefore not only issued a seductive prospectus and widely circulated it in France and abroad, but have also prepared a large quantity of hygienic products, such as bread, biscuits, dry cakes of all descriptions, liqueurs, &c., which are all prepared with sea-water, and are endowed with the most marvellous healing properties. In the prospectus it is stated distinctly that the use of these preparations renders all other medicines or medical treatment unnecessary. There is only one little point which requires explanation. The "inventors" state that their preparations are made with distilled sea-water; we would ask them what becomes of the mineral and organic matter contained in sea-water during this distillation? But *mundus vult decipi!*

THE additions to the Zoological Society's Gardens during the past week include a White-handed Gibbon (*Hylobates lar*) from the Malay Peninsula, a Brown Monkey (*Macacus arctcides*) from Burmah, presented by Mr. W. H. Newman; two Black Francolins (*Francolinus vulgaris*) from India, a Chukar Partridge (*Caccabis chukar*) from North-West India, presented by Major Newton Pauli; four Common Marmosets (*Hapale jacchus*) from Brazil, deposited; two Rough Terrapins (*Clemmys punctularia*), a Scorpion Mud Tortoise (*Cinosternon scorpoides*) from Trinidad, purchased.

CERTAIN MOVEMENTS OF RADIOMETERS[1]

THIS morning (Dec. 20) I received from Mr. Crookes an account of the behaviour of a kind of radiometer which he was so good as to construct at my suggestion. The consideration of an experiment mentioned in a paper of his presented to the Royal Society, which will shortly be read, and which he has kindly permitted me to refer to, suggested to me the desirability of investigating the effect of mere roughness of surface, all other circumstances being alike, and the disc of the radiometer being metallic, so that the two faces may be regarded as practically at the same temperature. Mr. Crookes's experiment, above referred to, led me to suspect that mere roughness might increase the efficiency of a surface, and I suggested to him some experiments with heated glass shades, or with a hot poker presented to the radiometer, the bulb being covered with a cool tumbler to defend it from being heated by the rays easily absorbed by glass. The result in every case answered my expectation; and it may be stated shortly that the law of the motion is that when the fly is hotter than the bulb the rough surface is repelled, or, say, the motion is positive; when cooler, negative.

I subjoin Mr. Crookes's memorandum of the results of experiment:—

"*Aluminium Radiometer* (1320), *one side of the vanes being ruled closely with a sharp knife.*

"1. Exposed to standard candle three inches off. Continuous *positive* rotation (ruled side repelled) at rate of 3¼ revolutions a minute.

"2. Exposed to non-luminous flame of a Bunsen burner three inches off. Continuous *positive* rotation at the rate of 7½ turns a minute.

3. The Bunsen burner removed. The positive rotation gradually diminished till it stopped. No negative rotation.

"4. The bulb heated with Bunsen burner. Good *negative* rotation; then stopped, and rotated *positively* till quite cold.

"5. Bulb covered with a cold glass shade, and a large red-hot ring applied round equatorially. *Positive* rotation, but not very strong.

6. On removing the shade and ring the positive movement soon comes to rest.

"7. Covered with a hot glass shade, *negative* rotation, with *positive* rotation on cooling (the same as 4).

"8. Plunged into hot water. *Negative* rotation.

"9. Removed from the hot water, and immediately plunged into cold. *Positive* rotation."

Results nearly identical were obtained with another radiometer described as "silver radiometer (1327), one side coated with finely divided silver, electro-deposited."

We must accordingly recognise three distinct conditions under which motion may be obtained in a radiometer, namely, (1) difference of temperature of the two faces, as in a pith radiometer, coated on one face with lampblack; (2) more favourable presentation of one face than the other, as in a radiometer with curved disks; (3) roughness of surface on one face (if this be really different from 2). These three conditions may be variously combined so as to assist or oppose each other, as the case may be, in producing motion.

---

[1] Paper read at the Royal Society, December 20, by Prof. G. C. Stokes, Sec. R.S. Continued from p 175.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

LONDON.—At a meeting of Convocation of the University of London held on Tuesday, the supplemental charter empowering the granting of degrees to women was considered. After a long and warm discussion a resolution appoving of the draft of the supplemental charter was carried by 242 against 132.

EDINBURGH.—A letter has been received from the Treasury intimating that 20,000*l*., the first instalment of the grant by the Government for the buildings of the University of Edinburgh, will be inserted in the estimates for this year.

LEEDS.—A course of ten lectures in connection with the Gilchrist Educational Trust will be delivered in the Albert Hall, Mechanics' Institution, Leeds, on Friday evenings, commencing Friday, January 25, by Prof. A. H. Green, M.A., on "The Geology of Coal;" Prof. L. C. Miall, F.G.S., on "Coal Plants and Animals;" Prof. T. E. Thorpe, Ph.D., F.R.S., on "The Chemistry of Coal;" Prof. A. W. Rücker, M.A., on "Coal as a Source of Power;" and Prof. J. Marshall, M.A., on "The Coal Question." An extra lecture will be given by Dr. W. B. Carpenter, F.R.S., on the "General Results of the *Challenger* Expedition." The admission is one penny.

HALLE.—The winter attendance at the University is 887, including, under theology, 189, law, 112, medicine, 106, philosophy and science, 480. Prussia is represented by 711. The attendance of foreigners is unusually small—England, 2, America, 5, Russia, 11, Austria, 20, &c. The corps of instructors numbers at present 90. The University library, one of the most valuable in Germany, possesses over 100,000 volumes.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, December 13, 1877.—On electro-striction, by Prof. Mills, D.Sc., F.R.S. If the bulb of an ordinary thermometer be coated chemically with silver, and then electrically with a metallic deposit, the mercury will traverse some portion of the scale, and finally take up a definite position independently of temperature. Of the metals hitherto worked with, copper, silver, iron, and nickel, constrict the bulb; zinc and cadmium distend it. The author shows that if y be the total obtainable effect after a time x; D the portion of it due to diametral constriction; L the portion of it due to longitudinal constriction; $d\,l$ two geometrical factors, we have, in the case of the cylindrical thermometer—

$$y = Dd^x + Ll^x,$$

D being always greater than L. For a spherical thermometer receiving more metal on its equatorial region than on its poles,

$$y = Dd^x - Ll^x.$$

For a spherical thermometer, with uniform deposition,

$$y = Dd^x.$$

The author determines in atmospheres pressure the total electrostrictive effect; and points out that, since the deposited metal can be removed by a chemical solvent, we are thus able to measure chemical effect in atmospheres pressure.

Linnean Society, December 20, 1877.—Prof. Allman, F.R.S., president, in the chair.—Dr. Maxwell Masters made some remarks on an interesting specimen of *Colletia cruciata* received from Sig. Fenzi, of Florence. In this case, from the same branch there proceeded shoots with broad, flattened, deltoid spines characteristic of *C. cruciata*, but also others with slender or cylindrical spines very similar to, but more cylindrical than, those of *C. spinosa*. It would thus seem this interesting specimen may tend to clear doubts which have arisen respecting the relation of these two species and that of *C. bictonensis*, Lindl. = *C. cruciata*, Hook.—Mr. Worthington G. Smith made some remarks on a fossil fungus, its zoospores being shown under the microscope. He also exhibited drawings, among others sections of *Boletus subtomentosus*, stating that in a specimen five inches in diameter there are 17,000 pores or tubes. Each pore, when cut across, shows 2,000 cells on the surface. The number of surface cells on the underside of a specimen is 36,000,000. The cells in an entire plant are calculated to be 61,500,000,000, and the number of spores produced by the same specimen, 5,000,000,000.—Mr. S. W. Silver exhibited a series of vegetable products, arrows, and other weapons, &c., from the Fiji Islands and New Caledonia, collected by Consul Edgar Layard. Among the specimens was a mass of the poison said to tip the native arrows with. The composition of this is supposed to be identical with that described by the Rev. Thomas Powell in the Society's *Journal* of last year.—A paper was read on the anatomy of the Elk (*Alces machlis*) by Prof. M. Watson and Dr. A. H. Young. In this a full account of the organs of digestion, generative system, myology, &c., was given, preceded by remarks on the literature, &c., of the subject.—An abstract of a communication, "Descriptions of new genera and species of phytophagous coleoptera," by Dr. J. S. Baly, was read by the secretary in the absence of the author.—The Algæ of the Arctic expedition, by Prof. Dickie, was a paper dealing with the collections made by Capt. Feilden, Dr. Moss, and Mr. Hart, who accompanied Capt. Sir G. Nares. It is noted that of fresh-water species there are representatives of fourteen genera, many of which are common to Europe. Of Diatomaceæ thirty-one genera and seventy species have been identified, most being marine. Seven species of olive-coloured Algæ are given, but it seems no marine examples belonging to the red series were obtained. The collection embraces an area between 78° and 83° north latitude. Then followed a memoir on the minute structure of *Stromatopora* and its allies, by Prof. A. Nicholson and Dr. J. Murie. This interesting form (or group) has long been a puzzle; different writers assigning it a place respectively among Corals, Hydrozoa, Foraminifera, Sponges, and Polyzoa. The authors treat the subject by discussing at length history and literature, the general and minute structure of a typical stromatoporoid, mode of occurrence and original constitution, classification, affinities, and systematic position. The following genera are defined:—*Stromatopora*, *Caunopora*, *Clathrodictyon*, *Stylodictyon*, *Stromatocerium*, *Pachystroma*, and *Dictyostroma*, and a number of new species described. They believe it (or them) to have been originally calcareous and not siliceous, as has been maintained by some, substantiating this by weighty facts and reasons. They discard the notion of its alliance with the Nullipores or belonging to the Corals, Hydrozoa, or Foraminifera, showing wherefore in absolute essentials it is deficient and therefore untenably associated with either. To certain of the Polyzoa some examples hold a striking resemblance in many respects (as likewise is specially the case with certain of the corals), and possibly further research may bridge difficulties in the way of classing it with the former group, but their researches do not completely justify this step. Neither, strictly, does it belong to the horny, siliceous, or calcareous sponges, as at present understood, though the tendency of the data point to the probability of sponge organisation predominating. In this case, however, by absence of spicules, &c., the existing group of *Calcispongiæ* could not contain the stromatoporoids which, under negative evidence, would form a new order of calcareous sponges—Stromatoporoidea.—Messrs. A. S. Bicknell, E. A. Floyer, and Capt. Legge were elected Fellows of the Society.

Meteorological Society, December 19, 1877.—Mr. S. H. Eaton, M.A., president, in the chair.—Commander E. G. Bourke, R.N., J. A. Douglas, W. H. La Touche, B.A., G. J. Pearse, W. S. Rogers, and W. Tyrer were elected Fellows.—The following papers were read:—Notes on the meteorology and physical geography of the West Coast of Africa from Cape Verd to the Cape of Good Hope, by Commander E. G. Bourke, R.N. This paper gives the results of the observations which the author made during the five years he was stationed on the above coast.—On the meteorological observations made by the Norwegian Deep Sea Exploring Expedition in the North Atlantic in 1876 and 1877, by Prof. H. Mohn. This expedition has been organised in order to carry out for the North Atlantic and the Arctic Ocean an inquiry similar to that conducted by the *Challenger* Expedition. The vessel employed was the *Vöringen*, of 400 tons burthen, and the period the summer months of 1876 and 1877. The barometrical observations were taken at first with a mercurial barometer and afterwards with an aneroid which was compared daily with the mercurial barometer on board. The temperature was obtained by a special screen hoisted up on the fore-stay. It was found that this gave very satisfactory results. The experiments conducted with a screen similar to that used by our Meteorological Office on ship-board gave readings too high when the sun shone on it. The sling thermometer was also tried, and gave a temperature on the mean a shade below the screen in the rigging. The wind observations were taken with an anemometer, and Prof. Mohn describes his own anemometer at length, and deals with its corrections in detail. The speed of the ship was determined by a special logging machine, and by this means and the anemometrical observations, the true motion of the wind was ascertained. The part of the paper which presented most novelty was that referring to the evaporation of the sea-water. Two different forms of atmometers were described, both of them devised by Prof. Mohn, and the theory of their action and of the errors to which the experiments were exposed are carefully considered. The paper concluded with tables of the diurnal range of the various meteorological elements for the period of observation.—Report on the phenological observations during 1877, by the Rev. T. A. Preston, M.A. As a rule, the same order of flowering of plants is observed this year as in 1876, viz., that plants came into flower first in the south-west of England and then in regular order to the north of Lincolnshire, where plants were latest in coming into flower. From the tables accompanying the report may be deduced the general state of the weather as regards temperature, and to a certain extent moisture. There is no doubt but that damp acts more powerfully than cold in retarding the flowering of some plants and this has been particularly evident this year. The year, as a whole, has been very unfavourable to vegetation; the bitter cold of May checked the growth of plants, and by the autumn there was comparatively little new wood, and that not properly ripened.—Note on a peculiar fog observed at Kew on October 18, by G. M. Whipple, B.Sc., F.R.A.S.

Royal Microscopical Society, January 2.—Dr. J. Millar in the chair. A paper was read by Dr. Bartlett on the detection of toxic matter connected with typhoid and other enteric diseases, in the course of which he gave an account of his attempts to trace to its ultimate source the cause of a recent outbreak of typhoid fever, and showed that whilst chemical analysis had failed to discover any impurity either in the water or milk, he had been able, by means of microscopical examination, to detect in the water certain bodies, presumably of a fungoid character, which were identical with those found in the bowels of persons who had succumbed to the disease.—Mr. Slack brought before the notice of the meeting a section of bone of *Megalosaurus bucklandii* and its remarkable resemblance to the structure now identified as peculiar to birds, was pointed out by Mr. Charles Stewart.

PARIS

Academy of Sciences, January 7.—M. Fizeau in the chair.—M. Daubrée was elected vice-president, from the Section of Physical Sciences (the other candidates being MM. Wurtz, Chevreul, and Blanchard).—M. Peligot reported on volumes just published, or being published, by the Academy. Vol. xxxix. of the *Mémoires* is devoted chiefly to researches by M. Chevreul, vol. xli. to researches by MM. Becquerel; a second volume on the transit observations, relating those at Pekin and St. Paul's Island, has been published; a memoir on *Phylloxera vastatrix*, by M. Cornu, appears in vol. xxvi. of the *Mémoires des Savants Étrangers*. The Academy lost by death, in 1877, one member, M. Leverrier, and five correspondents, MM. Santini, Hofmeister, Braun, Weddell, and Gintroc.—M. Faye presented, in the name of the Bureau des Longitudes, the first volume of its *Annales*. In these *Annales* will be inserted, with additions, the memoirs which the Bureau formerly published in the *Connaissance des Temps*, its circle of activity having been enlarged.—On persulphuric acid, a new oxygenated acid of sulphur, by M. Berthelot. This is obtained pure and anhydrous, by making the electric *effluve* act, with strong tension, on a mixture of equal volumes of dry sulphurous acid and oxygen; it is got in the dissolved state by electrolysis of concentrated solutions of sulphuric acid, or by mixing with care a solution of oxygenated water with sulphuric acid, concentrated, or diluted with less than one equivalent of water. At a temperature near zero, it crystallises, and resembles, in its general aspect, anhydrous sulphuric acid, only it has longer, and thinner, and transparent needles. The formula, determined variously, is S_2O_7. Heated in a flame, the substance is immediately decomposed into oxygen and anhydrous sulphuric acid. In air it gives off thick fumes. In concentrated sulphuric acid it dissolves without liberating oxygen. In water it dissolves, giving thick fumes and effervescence, &c.—On a new flat regulating spiral for chronometers and watches, by M. Phillips. The theory of this is explained.—On some new modifications in the telephone, by M. Breguet. According to indications by MM. Garnier and Pollard, a thin plate of sheet iron is arranged with the end of a blacklead pencil pressing slightly on the central part; plate and pencil are connected by wires of ordinary lines with the two ends of the bobbin wire of a Bell telephone, which has, instead of the magnetic bar, a bar of soft iron. A battery of two Laclanché elements is placed in the circuit. The plate, vibrated by the voice, causes variations in the blacklead, and so in the resistance of the circuit and the intensity of the permanent current, which produces alternative attractions and non-attractions in the electromagnet of the receiving telephone; thus the voice is reproduced. M. Breguet is hopeful of an increased intensity of effect by such a method.—On the production and properties of a new suction-ram without air-reservoir, capable of drawing water from all depths, by M. de Caligny.—Density of liquid oxygen, by M. Pictet. The author experimentally confirms M. Dumas' view, who obtained the expression $\frac{16}{16} = 1 = \delta$, for the solid, and probably the liquid state also. The jet of oxygen showed a strong polarisation of the electric light, indicating the presence of solid dust, probably small crystals of solid oxygen.—On the quartic of Steiner, by M. Amigues.—On a single principle containing the whole theory of curves and of surfaces of any order or class, by M. Serret.—On a theorem of M. Villarceau; remarks and consequences, by M. Gilbert.—On phenomena of dispersion in metallic reflection of polarised luminous or calorific rays, by M. Mouton. The greater the wave-length the longer is the interval during which mirrors act like glass on light, simply impressing a certain rotation in the original plane of polarisation, and the shorter therefore is that in which the original rectilinear polarisation of the incident ray is changed by the fact of reflection into elliptic polarisation.—On normal ethyloxybutyric acid and its derivatives, by M. Duvillier.—Researches on the intracellular alcoholic fermentation of plants, by M. Muntz. Plants kept in air give no trace of alcohol; those kept in nitrogen give a quite appreciable quantity, and they continue to live and grow. These facts are a confirmation of M. Pasteur's views.—On the inversion and alcoholic fermentation of cane-sugar by mouldiness, by M. Gayon.—Some remarks on the origin of alcoholic yeast, by M. Trécul.—Verbal response of M. Pasteur.—On a new gorilla from Congo, by MM. Alix and Bouvier. This seems, like chimpanzees, to have more arboricolar habits than the *Gorilla gena*. The name of *G. Mayema* is given it from that of the negro chief of the village near which it was killed.—On the formation of fibrine of the blood studied with the microscope, by M. Hayem.—On a process for obtaining recomposition of the light of the solar spectrum, by M. Lavand de Lestrade.

RAYLEIGH'S "THEORY OF SOUND"

The Theory of Sound. By J. W. Strutt, Baron Rayleigh, F.R.S. Vol. I. (London: Macmillan and Co., 1877.)

THE author, who already, by a series of interesting treatises belonging to different branches of mathematical physics, has acquired a respected name in the domain of science, undertakes to give a complete and coherent theory of the phenomena of sound in the work above mentioned, the first volume of which has recently been published; and he does this with the application of all the resources furnished by mathematics, since without the latter a really complete insight into the causal connection of the phenomena of acoustics is altogether impossible. We must confess that, even in spite of the most intense exertion of the powers of mathematical analysis, in the present state of its development several problems remain unsolved, for which, indeed, the conditional equations are known, but for which it has not yet been found possible to carry out the calculation.

The author will merit in the highest degree the thanks of all who study physics and mathematics if he continues his work in the manner in which he has begun it in the first volume. The separate treatises in which the acoustic problems that have been solved hitherto are discussed, are for the most part dispersed in the publications of academies or of scientific societies, which can be found only in larger libraries, and which frequently are not at all easily traced. But even if one has found a treatise of this kind and reads it, it happens often enough that the author refers in his quotations to other works quite as difficult of access, the knowledge of which is necessary for understanding his treatise. Thus the zeal of the student is paralysed by a number of purely external difficulties, and the ordinary result at which an intelligent student arrives after a few attempts in this direction, is that for problems in which he takes great interest he prefers starting anew to find the solution, rather than trying to hunt for it in libraries. Even if we must admit that the insight into the essence of a problem for which one has found the solution oneself is much deeper and clearer than when one has obtained the solution from some other author, yet an enormous amount of time is thus lost, and the survey of the whole extent of solvable problems remains incomplete. A survey of this kind, however, is necessary for all who wish to work at the progress of science themselves. For in order to obtain decisive results by new scientific investigations it is necessary above all things to be quite clear with regard to the question for which forms of experiment or of observation the theoretical deduction from principles can be carried through as purely as the experiment itself. I know by experience that a number of young physicists lose their time and their zeal by trying to solve problems which, taken by themselves, are very interesting, but for which at present the deductions from the theoretical principles for the given case can only be drawn in coarse approximation, and where the experiments cannot be freed from important sources of error.

While praising Lord Rayleigh's book as a means of overcoming the difficulties described, I do not at all wish to designate it as a mere compilation. On the contrary, it is a perfectly coherent deduction of the special facts from the most general principles, according to a uniform method and in a consequent manner. The mechanical principles of the doctrine of minute oscillations are contained in the present volume and are developed in greater generality than in any other book known to me. For this purpose the author in the first chapter explains the general physical principles of sound, of its propagation, of pitch and its dependence on the rapidity of vibration, of the musical scale, of the quality of sound and its dependence on the harmonic over-tones; and in the second one the doctrine of the composition of harmonic motions of either equal, or nearly equal, or consonant numbers of vibrations, and further illustrates them by the description of the physical phenomena and methods in which the principles developed are applied, and to which belong the doctrines of musical beats and of the physical methods to render the forms of vibrations visible.

Then follows the development of the most general peculiarities of oscillating motions, first, in the third chapter, for mechanical systems to the motion of which only one degree of freedom is allowed, and then, in the fourth chapter, for systems with a finite number of degrees of freedom. There is a great multitude of peculiarities common to the most heterogeneous sounding bodies, which up to the present have mostly been found in certain instances only, but which can also be deduced from the most universal form of the motion-equations of systems of one or more degrees of freedom of motion. The author in the form of the equations and in the manner of denotation, closely follows the "Natural Philosophy" of Thomson and Tait; in fact the whole manner of treatment of the mathematical problems corresponds so closely to that adopted in the work just mentioned, that Lord Rayleigh's book may be looked upon as the acoustic part of the excellent handbook of the two celebrated physicists named.

With all systems of this kind if there are no exterior forces acting upon them, we find, on the whole, a number of proper tones equal to the number of degrees of freedom, and the pitch of which does not depend on the amplitude of the vibrations as long as this one remains small enough. Exceptionally, however, several of these proper tones may be of equal pitch. If there is no friction or dissipation of energy the amplitude of every kind of oscillation remains constant. To each separate proper tone a certain form of motion of the whole system belongs; so that the directions and magnitudes of the displacement of the separate points of the system are different in each case. Each arbitrary motion of the system produced in any arbitrary manner, may be regarded as a superposition of these forms of vibrations belonging to the various proper tones of the system. In order to find the amplitude and phase of these different vibrations for a given original displacement and of given velocities of its different parts, quite similar methods are adopted as those which are employed to develop a given periodical function into one of Fourier's series; only the whole method here becomes far more intelligible and has a thoroughly certain foundation, because we have to do with a finite number of unknown factors instead of with the infinite number of continuously succeeding values of a function, with finite sums instead of with integrals or with infinite series. Of course for Fourier's series as well as for the developments of Laplace by means of spherical harmonic functions the proof for the correctness of their values can also be furnished in the case of continuous functions. For a large number of other functions which are given by differential equations of the second degree this proof results, under certain suppositions regarding the continuity of the functions and the limit conditions, from the theorems of Sturm and Liouville, which Lord Rayleigh explains when speaking of the vibrations of strings of unequal thickness. Yet in mathematical physics we are still compelled to employ a great number of series-developments of functions which do not belong to this class; and even the vibrations of rods and plates are cases in point. In this respect the treatment of the problems mentioned with a finite but arbitrarily large number of degrees of freedom of motion is interesting also with regard to analysis.

For vibrating systems of one degree of freedom, the oscillations of which are subjected to damping, the doctrine of the laws of resonance is developed in the third chapter. The author calls the vibrations which are continuously maintained by the influence of a periodical force acting externally, *forced vibrations*. In all cases their intensity is greatest when their period of vibration, which equals the period in which the force changes, is also equal to the period of the system vibrating freely and without friction. For the relations between the intensity and the phase of the co-vibration, between the breadth of the co-vibration in case of small alterations in the pitch and the degree of damping, which I had myself proved for certain instances and used for certain observations, the general proof is given here. The author has further employed these chapters to set up certain general maxims respecting the direction and magnitude of the corrections which must be made in cases where one cannot completely solve an acoustic problem, but can only find the solution for a somewhat altered vibrating system. These are like the outlines of a "theory of perturbations" applied to acoustic problems. The author illustrates these maxims by many various examples. Thus, for instance, he replaces a string by an imponderable stretched thread which carries weights either in the middle only or at certain distances from each other; or a tuning-fork by two imponderable springs with weights at the ends.

For vibrations of very small amplitude, the forces which tend to lead the moving points back to their position of equilibrium may always be considered proportional to the magnitude of their distance from the position of equilibrium. As long as this law holds good, the motions belonging to different tones are superposed, without disturbing one another. But when the vibrations become more extensive, so that the law of proportionality just named no longer applies, then perturbations occur which become manifest by the appearance of new tones, the combination tones. In my book on acoustic sensations ("Die Lehre von den Tonempfindungen") I have myself explained this manner of origin of the combination tones, only for the motion of but a single material point. In Lord Rayleigh's book this explanation is given with reference to any compound vibrating system of one degree of freedom, and it is further amplified with regard to the manner in which the forces deviate with the displacements from the law of proportionality.

Certain laws of reciprocity, of which I had given single instances in my investigations on the vibration of the air in organ pipes, may be proved in a general way for all kinds of vibrating elastic systems. If on the one hand at point A an impulse is given, and the motion at point B is determined after the time *t* has elapsed, and if on the other hand an impulse is given at point B in the direction of the motion, which occurred there, and, after the time *t*, the motion-component falling into the direction of the first impulse is examined at point A, then the two motions in question are equal if the impulses were equal.

Chapters VI. to X. of Lord Rayleigh's book treat of the vibrations of strings, rods, membranes, and plates. The vibrations of strings have played an important part in acoustics; their laws are simple, and the physical conditions which the theory demands are fulfilled with comparative facility, different modes of producing the tones may be employed, and a number of various motions may thus be produced. It is just because the physical phenomena in connection with strings were well known, that the observation of the way in which the ear is affected by their various modes of vibration has materially facilitated the solution of the problems of physiological acoustics. The musical importance of strings rests on the circumstance that the series of their proper tones corresponds to that of the harmonics, the vibration-numbers of which are entire multiples of those of the fundamental tone. For this reason, if the motions of many proper tones are superposed on one string, a periodical motion again results, and this is the cause why on strings we can produce notes of the most varied quality. We need only remember how differently the same string sounds according to whether it is plucked with the finger or with a metallic point, whether a violin bow is drawn across it or whether it is caused to vibrate by means of a tuning-fork

In this chapter less new work remained to the author; however, this example shows how much easier it is to understand all these separate problems if they are not treated separately but developed in coherent representation, after the most general principles, the validity of which is independent of the special peculiarity of the case, have been first explained.

The short chapter VII. gives the laws for the longitudinal and torsional vibrations of rods; the laws are simple and resemble those of the open and stopped organ pipes. The lateral vibrations of rods, during which these bend, give more complicated analytical expressions; their proper tones do not form a harmonic series, but are given by the roots of a transcendental equation. The tones are different according to whether one or both ends of the rod are free to rotate and to move, or free to rotate, but hindered from moving (supported), or hindered from rotating and moving (damped). With this more complicated problem the advantage of first treating of the general principles becomes clearly apparent. The forms of the simplest vibrations are calculated and represented graphically. The mode of vibration of a stretched rod, for which Seebeck and Donkin have already given the solution, is also treated here in order to determine the influence of rigidity upon the vibrations of strings.

Then the vibrations of a uniformly-stretched membrane are investigated. This investigation is of more theoretical than physical importance, since it shows in a case which may be treated in an easier way, the peculiarities of vibrations which are capable of spreading in two dimensions. Unfortunately we have not yet succeeded up to the present in obtaining good membranes which would be fit for experiments of measuring in order to investigate, with some degree of exactness, how far theory corresponds with the experiment.

On the contrary, in the case of elastic plates, the vibrations of which the author treats in the last chapter of the present volume, the experiments can be made with more accuracy, while the analytical difficulties are so great that, on the whole, only few cases permit of a solution of the problem. Indeed, even the formulæ expressing the conditions which must be fulfilled at the edge of the plate have given rise to discussions. Poisson had thought that three conditional equations were necessary for the edge; Kirchhoff has shown that in reality only two are required. Lately M. Mathieu opposed this view. Lord Rayleigh has adopted Kirchhoff's views, and no doubt with perfect right. He gives the analysis of the latter of the vibrations of a circular plate, and has made an important addition of his own to the solvable cases, by teaching us how to deduce theoretically a series of vibration forms of square plates, at least for that case where they consist of an elastic substance the resistance of which to change of volume may be neglected; and these theoretical deductions sufficiently correspond with the forms observed. Also for elastic rings and for cylinders vibrating in the manner of bells, he has improved the theory in an essential point, by proving theoretically and experimentally, that the node lines of such plates execute vibrations in a tangential direction. These tangential vibrations are the ones which are first produced if the edge of a drinking-glass is rubbed with the wet finger.

The above survey will give an idea of the numerous contents of the book. As in the treatment of the separate problems it touches everywhere the limits of our present knowledge, it cannot but demand sound mathematical knowledge on the part of the reader. Yet the author has rendered it possible, by the very convenient systematic arrangement of the whole, for the most difficult problems of acoustics to be now studied with far greater ease than hitherto. He thus proves himself to be a philosopher who does not lose the liberty of intellectual supervision, even when he is occupied with the most abstruse calculations.

H. HELMHOLTZ

HINDUISM, BUDDHISM, AND ISLÂM

1. *Hinduism.* By Monier Williams, D.C.L. 2. *Buddhism.* By T. W. Rhys Davids. 3. *Islâm and its Founder.* By J. W. H. Stobart, B.A. (London: Society for Promoting Christian Knowledge, 1877.)

IT is a sign of the times that a "Society for Promoting Christian Knowledge" should undertake a series of works on "non-Christian religious systems." Nor is it a less striking characteristic of our day that it should entrust the work to scholars of so liberal a faith as Prof. Monier Williams and Mr. Rhys Davids. Dr. Monier Williams's volume on Hinduism forms a model of a popular exposition of a religious system. He explains with great clearness the historical *catena* of the sacred writings on which the Sanskrit religion was based. He delineates the various movements, from the Buddhistic reformation 2,500 years ago, down to the modern revivals among the Sivaite and Vishnuvite sects, which have developed the Vedic worship into that complex structure of ritual, dogma, and social institutions, which we call Hinduism. To the ordinary English reader, this little volume will reveal a different aspect of Hindu faith and morals from that which he has been accustomed to hear from the pulpit or missionary platform. He will find that the great questions of how a man should rule his life, and what prospect lies before him after he has done with this world, have formed the subjects of religious thought and practical experience, not less anxious nor less deep among the people of India than among the western races. The ethical replies which they have given to those questions differ more in form than in spirit from the higher beliefs of Christendom. The hard and narrow judgments of the elder Mill and the zealous statements of missionaries, have too long possessed the popular mind. Prof. Williams does not appear as the advocate or admirer of Hinduism. In fact he tacks on to the end of his book a proselytising page or two, which, however in accord with the object of the Society for which he writes, form a strange contrast to the scholarly tone of his volume.

Dr. Monier Williams's tours in India have enabled him to deal with the modern phases of Hinduism from a practical, as well as from the professorial point of view. Three features of Hinduism must be distinctly realised in order to understand its vitality and influence on the people. Hinduism represents, in the first place, a very ancient growth of worship and belief; and is invested with all the authority of age and unquestioned prescription. In the second place, it is a very modern religion, whose later developments have neither been reduced to, nor are restrained by, any systematic theology; which is, therefore, plastic, sensitive to every change in the popular beliefs or modes of thought; and which, in each province of India, takes on a local colouring adapted to the necessities or customs of the local population. In the third place, Hinduism is not only a religious system, but an all-powerful social institution. It forms the outcome of religious and philosophical thought in India during several thousands of years; it also represents the organised modes of life at which a great variety of tribes and races have slowly arrived. This threefold source of strength makes itself felt in every detail. To take one instance: Caste is enforced alike by the sanctions of ancient prescription, modern religion, and social utility. It articulates the population into communities, each bound together by ties of a useful, not less than of a doctrinal sort. Caste, with the feelings of kindred and family on which it rests, forms the substitute for a Poor-Law in India; it supplies a bond something like that which in America is felt by people who attend the same meeting-house or chapel; and it discharges many of the functions of the mediæval guilds of Europe, together with others which are effected less smoothly by modern Trades' unions. It has its disadvantages—some of them very serious ones; but it curiously resembles, in several of its judicial, social, and charitable aspects, the ekklesia of the early Christians.

Prof. Monier Williams might not accept this view, but we recommend his book as at once a scholarly and a practical exposition of Hinduism, in a cheap and popular form.

Mr. Rhys Davids has done his work well, but with a difference, in his little volume on Buddhism. He has rightly separated the facts (so far as we can ascertain them) of the history of the founder from the modern legends regarding him. He gives a careful and interesting narrative of the life, explains the doctrines which Gautama Buddha taught, and the system of morals which was subsequently based upon his precepts and example. Nothing could be better than some of the passages which bear upon the aspects of Buddhism in Ceylon, China, and Tibet. But it is to be regretted that the plan of the work permitted of so little space for its influence upon the mediæval forms of Indian ritual and belief. One of the most interesting pictures which we possess of a struggle between two great faiths is to be found in Hiouen Thsang's itinerary through India in the seventh century. The narratives of the Chinese travellers form, indeed, the first historical evidence of eye-witnesses with regard to Indian manners and beliefs. They supply a key to the subsequent religious developments among the Hindus, and well merit a fuller notice. Another point of deep interest on which Mr. Rhys Davids' volume is, perhaps necessarily, silent, refers to the industrial aspects of Buddhism. It is well known that architecture in India began with the requirements of Buddhism, and that those requirements profoundly affected its whole subsequent history. Moreover, the Buddhist monks were not only missiouaries; they were artists, or at any rate artisans, who carried a new civilisation as well as a new faith to the Asiatic races. Thus it was a Buddhist monk of Corean ancestry who, between 662 and 672 A.D., published the secret of making translucent pottery in Japan. The ritual of Buddhism stamped its influence on the characteristic national industry both of Japan and China; and as late as 1212 we hear of a celebrated Japanese potter, accompanied by a Buddhist monk, going on a mission to the mainland to acquire the deeper mysteries of ceramic art. The vast number of Buddhist records did much to develop the art of writing, while the circumstance that its theology centres around a single human life, gave a biographical and historical impulse to the nations who adopted it, which is unknown among the followers of the older Bráhmanical faith. Mr. Rhys Davids' book is silent on these points. But it is only just to him to add that he has managed to compress a vast amount of thought and information, of a kind perhaps more important from the Society's point of view, into his 250 pages.

Mr. Stobart's Islám is conceived in a less philosophical spirit. "Light and darkness," he says, "are not more opposed than the loving doctrines of the Gospel and the vengeful spirit of the Koran." "Darkness and retrogression are engraved on every page of the Preserved Book." This is his conclusion of the whole matter, but it fails to explain the secret of one of the great historical movements which has deeply influenced mankind. Scraps of piety are scattered throughout the book, sometimes with a curious effect. Here is Mr. Stobart's conception as to how a chapter on the Ancestry of Mahomet should begin:—"We have the assurance that Noah was 'a perfect man and walked with God' (Gen. vii. 9); and as a 'preacher of righteousness' (2nd Peter, ii., 5), having with his sons been witness of the flood, handed down to his posterity the worship of the True God." Further quotation is unsuitable. Mr. Stobart's book will supply a convenient but misleading compendium for those who wish to know a little about the subject. It reproduces the bigotry which disfigured Sir William Muir's "Life of Mahomet," on which it is chiefly based, without the scholarship which rendered that Indian civilian's four volumes the standard English work on Islám.

OUR BOOK SHELF

Physical Chemistry. By N. N. Lubavin. Part II. 8vo. 460 pp. (Russian.) (St. Petersburg, 1877.)

WE are glad to notice the appearance of the second and last part of M. Lubavin's most valuable work, which is devoted to the most important departments of physical chemistry. In this part the author deals with chemical reactions in general and discusses under this head some of the various theories advanced as to the distinctive characters of chemical processes; the stechiometrical laws of Dalton, Gay-Lussac, Faraday, Dulong and Petit, &c., all figures relative to these laws being given in a tabular form; chemical combinations, *i.e.*, the formation of compounds by heat, light, and electricity, and under the influence of other bodies; the development of energy during chemical processes, this chapter containing nineteen very useful tables; changes of properties of bodies when entering into chemical combinations; the decomposition of bodies by heat, electricity, and light; mutual decomposition; and chemical isomerism. Under each of these heads we find a considerable amount of most valuable information, skilfully selected from the already immense literature of that subject, and always giving the last results of recent investigations. The work will be thus of a great value for the student, giving in one volume of 800 pages of compact print a reliable and often very complete *exposé* of the results reached by science in this most important department.

Elementary Theorems Relating to the Geometry of a Space of Three Dimensions, and of Uniform Positive Curvature in the Fourth Dimension. By Simon Newcomb. (From the *Journal fur Mathematik*, Band lxxxiii., Heft 4, 1877.)

THIS is an interesting contribution to the subject treated of by Riemann, Helmholtz, and others, and in this country by Prof. Clifford. The question is considered from the standpoint of elementary geometry instead of by the analytic method which has been commonly employed by writers on non-Euclidian Geometry.

Quatre Modèles, représentant des Surfaces développables, avec des Renseignements sur la Construction des Modèles, et sur les Singularités qu'ils représentent. Par V. Malthe-Bruun et C. Crone; *avec Quelques Remarques sur les Surfaces développables et sur l'Utilité des Modèles.* Par M. le Dr. H. G. Zeuthen. (Copenhague, 1877.)

IN the third edition of Salmon's "Geometry of Three Dimensions" there is (p. 289) a description of a simple way of making a model of a developable surface, attributed by Prof. Cayley to Mr. Blackburn. This suggested to Dr. Zeuthen the idea of drawing on the same model curves having contact of different orders with the edge of regression (*l'arête de rebroussement*) and of constructing new models of a very elementary nature, showing the principal singularities of developable surfaces.

Full accounts are given in a pamphlet (15 pp.) and directions for putting the models together, which consist of flat cardboard marked in accordance with the printed descriptions. The whole is contained in a neat quasi-envelope (nine inches by seven).

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.]

Glass for Reflectors

YOUR last number (vol. xvii. p. 226) contains a very interesting paper by Mr. Norman Lockyer, in which that gentleman quotes the following passages from Mr. Grubb's paper :—

"For the 4-foot disc of glass for the Paris reflector, in place of that which has so recently resulted in failure, the St. Gobain Glass Company require twelve months' time to perfect (although, be it remembered, the quality of the glass is here of no consequence whatever); and I have been myself in correspondence with the principal glass manufacturers here and on the Continent, and not one of them is willing to undertake even a 6-foot glass disc; so that it would appear that, above that size, the silver-on-glass mirrors are out of the question." .... "The other great difficulty in the manufacture of reflectors is the annealing of the disc, and I believe it is this difficulty which limits to so narrow an extent the production of glass discs for silver-on-glass mirrors."

It may be interesting to your readers to know that an attempt is now being made to entirely overcome the apparently insurmountable difficulties so clearly pointed out by Mr. Grubb, and to obtain at any time without delay, and at a very small cost, discs of glass suitable for making silvered reflectors from 6 to 8, or even 10 feet in diameter.

It is almost impossible to over-rate the difficulty of producing massive discs of glass such as the one employed for the 47¼-inch reflector of the Paris Observatory, weighing, as it did, no less less than 1,546 lbs. in the rough, for, however carefully annealed such a mass of brittle, slow-conducting material may be, it will always be liable to unequal expansion, deflection, and fracture.

Fortunately, however, we have commercial plate glass to fall back upon; plates of 1 to 1½ inch in thickness can be readily made and perfectly annealed, and it is to the substitution of these large and comparatively thin sheets of glass, in lieu of thick cast masses, that my attention has been chiefly directed.

It is perfectly well known that plates of 1 to 1½ inches in thickness, if of large area, are subject to a great amount of deflection and consequent distortion of the image, which no ordinary support or backing can prevent. Several modes of converting such thin discs of commercial plate glass into efficient reflectors are about to be put to the test of practical experiment for the 50¼-inch silver-on-glass reflecting telescope which I am making and erecting at my residence on Denmark Hill.

Any attempt to support a disc of this diameter of 1½ inch in thickness against a cucheon of any kind, or loosely against a plane, must end in failure; nor can we hope to escape the difficulty by cementing the glass to any foreign substance whose power of conducting heat and rate of expansion differs from that of glass, as a giving way of the cement would be only a question of time, while distortion would result from unequal expansion of the two different materials. An intermediate course has therefore been adopted.

A strongly ribbed hollow cellular casting is made of iron 52½ inches in diameter, and 13 inches in thickness, weighing 1,400 lbs.; after slowly cooling in its mould, it will be again heated to about 900° F., and then be again slowly cooled; the whole of the external skin of the casting will be turned off in the lathe, and its face made into a true plane, less the final process of scraping; it will then be thrice annealed in oil, each time slowly raising the temperature from 60° up to 600° F., and each time slowly cooling it again. When all undue tension has thus been got rid of, its face will be finally scraped to a true plane, and a small spiral channel $\frac{1}{16}$ of an inch deep, and the same in width, will be formed on the flat face, the channels being about ½ an inch apart from each other, and extending from the centre nearly to the outer edge of the metal surface. One side of the glass disc having been previously ground flat by the plate-glass manufacturer, will have a second grinding on the grooved plane, so as to insure perfect contact all over its surface; the emery having been all carefully removed, the surface of the iron plane is to be slightly moistened with olive oil, and the disc of glass replaced upon it. A flanged iron ring will then be placed around the glass disc, and screwed firmly to the iron surface, leaving a clear annular space of about ⅜ of an inch wide between the periphery of the glass disc and the ring; a permanently tenacious viscous matter (of the character of soft marine glue) will then be poured into this annular space, forming an air-tight junction between the iron plate and the glass surface, and at the same time admitting the glass to expand or contract freely. A partial vacuum will then be formed beneath the glass by exhausting the air through a central hole communicating with the spiral groove; the glass disc will then be held firmly in contact with the entire surface of the iron plane, which, however, is free to slide under the glass when undergoing expansion or contraction. I have found by repeated experiments (many years ago) that plate glass (say of ¼ of an inch only in thickness) so held on to an unyielding plane, may be repeatedly struck by the rounded face of a heavy wooden mallet, with the greatest violence, without producing a single fracture, so complete is the support thus afforded.

It is important to bear in mind that a glass disc so held does not rest on its lower edge when placed in a vertical position, nor are the upper portions of the plate allowed to press on, and be supported by the lower ones, as is inevitably the case with a mirror loosely suspended in a sling in the ordinary manner, but on the contrary, every portion of the glass disc is sustained and supported in position by atmospheric pressure, and held flatly and firmly against a corresponding portion of the unyielding iron plane, free from any accumulated downword pressure.

The expansion by heat of plate-glass and cast-iron are in round numbers as 19 is to 22, and the differential amount of this expansion between the extreme range of summer and winter temperatures, would cause the iron to exceed the diameter of the glass by about $\frac{1}{100}$ of an inch;—this minute sliding motion of the two smooth planes upon each other would not in the slightest degree alter the curved face of the mirror.

The glass disc having been thus finally and permanently attached to the iron plane, the latter would be supported in its cell by bands passing round it as usual, and with a system of triangular supports at the back. The weight of this strong-ribbed hollow cellular plane, of 13 inches in thickness, is only 1,400 lbs., while a disc of equal diameter in speculum metal, if only 4¼ inches in thickness, would weigh about 2,700 lbs.; hence such a compound metal and glass reflector is lighter than a solid cast glass one, and but little more than one-half the weight of a reflector made of ordinary speculum metal, while its thickness being three times as great as the latter, it would, when in use, and also while undergoing the polishing operations, be perfectly free from deflection.

Hitherto I have spoken only of the mode of mounting the glass disc on its iron support; it now remains to convert the flat surface of the glass disc into a shallow concave reflector. For this purpose I have made experiments in turning glass concaves with a diamond-cutting tool mounted on a slide-rest, and I have found that in this way glass affords nearly the same facilities for shaping in the lathe that iron or brass would do under similar conditions; it therefore follows that lenses of all shapes and sizes may be brought approximately to a true figure with very great ease and rapidity.

Satisfied with this result, I am now erecting in my laboratory a lathe of peculiar construction and specially adapted to this purpose with a bed fifty feet in length, and having a fifty-four inch diameter face plate at each end of the mandril. A massive radius-bar or frame of double the intended focal length of the reflector, moves on an adjustible pivot attached to the lathe-bed, while the other end of the radius frame carries a slide-rest in which a diamond-cutting tool is mounted, and by means of which a spherical concavity is rapidly and truly turned over the whole face of the glass disc, and of any desired radius, while a second plate of glass or metal is turned into a convex surface on the other face-plate of the lathe, thus furnishing a convex grinder of the exact same radius as the concave reflector. Special arrangements are made to neutralise any difference in the length of the radius-frame by expansion or contraction during the turning operation, and provision is also made for gauging to the

$\frac{1}{100}$th of an inch the focal length of the convex and concave surfaces under operation.

Although I have heretofore described the cellular casting as having a flat face, it will be obvious that if made into a concave corresponding with the intended focal length of the reflector that much thinner sheets of glass than those before named may be employed by first bending them to the required curve and fitting them by grinding to the concave iron surface, so that a glass reflector can on this principle be made just as large as a plate-glass manufacturer can produce an ordinary thin plate.

A description of the novel arrangements which I employ for grinding and polishing the spherical concave reflector, and its conversion into a paraboloid of revolution would carry me far beyond the already too lengthy remarks I have made, and which had for their primary object simply to show that we may still have good reason to hope that silver-on-glass reflectors of large diameters are within our reach.

HENRY BESSEMER

Denmark Hill, January 21

A Telephone Without Magnetism

FOR some time past I have been experimenting with the view of transmitting articulate sounds through wires without the aid of electricity or magnetism.

I have now been quite successful, my experiments proving that the sounds of the human voice can be carried by *vibrations* through considerable lengths of wire.

Last night conversation was carried on with ease between *four* individuals, situated in different rooms. Piano music, singing, laughing, and breathing, were all clearly transmitted to the ear.

The whole distance would be about fifty yards.

The communication was effected by means of a mouth-piece with a vibrating disc in connection with the wire.

Glasgow W. J. MILLAR

Change of Habits in Toads

WHILE prosecuting my field-work as Palæontologist of the United States Geological Survey of the Territories, under the direction of Prof. F. V. Hayden, in Colorado, during last season, I had the opportunity to make some very interesting observations in relation to a change of habits in the common toad (*Bufo americana*). The district referred to is that portion of the great plains which lies immediately adjacent to the eastern base of the Rocky Mountains, and which is traversed by the South Platte River and its tributaries there.

The valleys of these streams are broad and shallow, and the streams heading in the immediately adjacent mountains have an abundant flow of water; so that large tracts of land in all those valleys have been brought under cultivation by irrigation. Irrigation is necessary in all that region, for it lies within that portion of the United States domain upon which the annual rainfall is insufficient for the purposes of agriculture.

With the irrigation of the land came increased and perennial vegetation; with that came increased insect-life, and with that an increase of birds and toads. The irrigating ditches are everywhere numerous, and during the season of growing crops they are frequently visited by men to regulate the flow of water to the land.

This and other circumstances disturb the toads that frequent the shades of the herbage which grows upon the borders of the water. It is no uncommon thing for toads as well as frogs, to jump into the water when disturbed, but the habit of the former is to make a shallow dive, rise immediately to the surface, and swim upon it by a sweeping curve to the shore again, not resting until the brink is gained, upon which they tarry a while before coming upon the land.

Frogs, on the contrary, when disturbed, make a strong dive directly to the bottom, upon which they lie prone, with the legs flexed against the body, and into the mud of which they settle themselves a little. Here they remain and exhaust the patience of one who may attempt to wait for them to rise. Now the toads in this irrigated region have adopted precisely these com habits of the frogs when disturbed upon the borders of ditches, as I repeatedly witnessed. I regard this as the resumption of an instinctive trait that has been potentially transmitted from a former race of Anourans that were less differentiated than frogs and toads are now from each other; and that the lately introduced change of physical conditions in the region has caused the toads to resume habits which the frogs have never abandoned.

Washington, D.C., January 6 C. A. WHITE

Talking Photographs

THE article from the *Scientific American* on the phonograph which is quoted in NATURE, vol. xvii. p. 190, concludes as follows:—"It is already possible, by ingenious optical contrivances, to throw stereoscopic photographs of people on screens in full view of an audience. Add the talking phonograph to counterfeit their voices and it would be difficult to carry the illusion of real presence much further."

Ingenious as this suggested combination is, I believe I am in a position to cap it. By combining the phonograph with the kinesigraph I will undertake not only to produce a talking picture of Mr. Gladstone which, with motionless lips and unchanged expression shall positively recite his latest anti-Turkish speech in his own voice and tone. Not only this, but the life-size photograph itself shall move and gesticulate precisely as he did when making the speech, the words and gestures corresponding as in real life. Surely this is an advance upon the conception of the *Scientific American*!

The mode in which I effect this is described in the accompanying provisional specification, which may be briefly summed up thus: Instantaneous photographs of bodies or groups of bodies in motion are taken at equal short intervals—say quarter or half seconds—the exposure of the plate occupying not more than an eighth of a second. After fixing, the prints from these plates are taken one below another on a long strip or ribbon of paper. The strip is wound from one cylinder to another so as to cause the several photographs to pass before the eye successively at the same intervals of time as those at which they were taken.

Each picture as it passes the eye is instantaneously lighted up by an electric spark. Thus the picture is made to appear stationary while the people or things in it appear to move as in nature. I need not enter more into detail beyond saying that if the intervals between the presentation of the successive pictures are found to be too short the gaps can be filled up by duplicates or triplicates of each succeeding print. This will not perceptibly alter the general effect.

I think it will be admitted that by this means a drama acted by daylight or magnesium light may be recorded and reacted on the screen or sheet of a magic lantern, and with the assistance of the phonograph the dialogues may be repeated in the very voices of the actors.

When this is actually accomplished the photography of colours will alone be wanting to render the representation absolutely complete, and for this we shall not, I trust, have long to wait.

WORDSWORTH DONISTHORPE

Prince's Park, Liverpool, January 12

Sun-spots and Terrestrial Magnetism

I BEG to direct Prof. Piazzi Smyth's attention to an article in the *Annuaire du Bureau des Longitudes* for 1878 by M. Faye, entitled "La Météorologie Cosmique," in which this distinguished astronomer and meteorologist says:—"La période des taches, portée à $11^{\text{ans}},1$ par M. Wolf n'étant pas égale à celle des variations magnétiques ($10^{\text{ans}},45$), ces deux phénomènes n'ont aucun rapport entre eux." It thus appears rather premature to suppose that the sun-spot cycle and the terrestrial magnetic diurnal oscillation cycle are intimately connected. A. W. DOWNING

Greenwich, January 21

Great Waterfalls

IN reply to Mr. Guillemard's inquiry in NATURE (vol. xvii. p. 221) he will find some account of the Kávari or Cauvery Falls in the "Mysore Gazetteer," recently compiled under orders of the Indian Government, vol. ii. pp. 271–273 (Bangalore, 1876). copy is doubtless to be seen at the India Office Library.

Edinburgh, January 21 W. W. HUNTER

Mechanical Analysis of the Trevelyan Rocker

ALMOST every physical cabinet possesses one of Trevelyan's rockers, and yet it is rare to find one which always works well and gives complete satisfaction. Some two years ago having experienced this difficulty in New York, where I was then Professor of Physics, I requested Mr. Robert Spice, F.C.S., of 230, Bridge Street, Brooklyn, U.S., a very skilful constructor of ic instruments, and a thorough physicist, to make for me l of these rockers and ascertain, if possible, the conditions of success. After many experiments with rockers of different sizes and angles, Mr. Spice obtained a formula by which a perfectly satisfactory rocker can be constructed, as several trials since then, both in America and Europe, have convinced me. Believing that there are many other professors who feel interested in this matter I communicate to the readers of NATURE, at Mr. Spice's request, his analysis of the rocker.

Let ABCD be the principal section of the rocker. Draw an indefinite base-line through the points C and D. From the point B let fall the perpendicular BE, and from F the perpendicular FD.

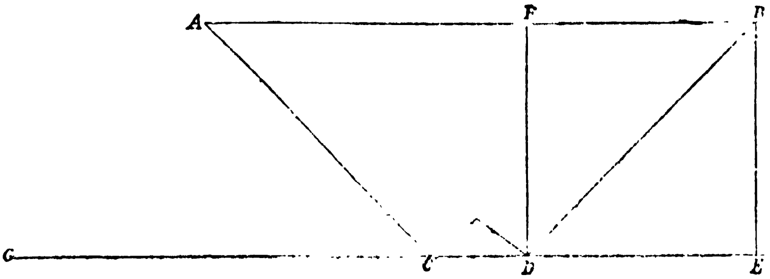
When the lead support raises (by expansion) the point D the point C becomes the fulcrum, and the line DE represents the complimentary arm of an imaginary lever CDE of the third order. In proportion as the distance CD is very small in comparison with the distance DE, in a like proportion will greater force be required to raise the rocker, and *vice versa*.

By experiment on a right-angled prismatic rocker (*i.e.* if the lines AC and BD be produced the angle at their intersection would be a right-angle) it was found that the most certain and pleasing effect was obtained when the distance CD was to the distance DE as 2 : 5.

In the case of a right-angled rocker as above, of course the distance DE = the distance DF.

By making the rocker-angle less than a right-angle, the distance DF would exceed the distance DE. This, it is believed, would be an advantage, as the leverage would remain constant and the additional weight would have the effect of raising the note.

The length of the rocker should be equal to twice AB. The length of the handle should be four times AB. Finally, in practice, the angles C and D are slightly flattened, by filing, to prevent adhesion to the lead by sinkage, also to gain a larger heating surface.



The lead should have the form shown in the section below, and should weigh from three to four pounds.

No Butterflies in Iceland

A FEW months ago, at a meeting of the Linnean Society, Mr. McLachlan, when speaking of the various species of butterflies brought to England from the far north by the last English Arctic expedition, mentioned incidentally that there were no butterflies in Iceland.

On looking up some old books on the subject, in which I had the most able assistance of Mr. Erickr Magnussen, of Cambridge, we found at folio 602 of a book entitled, Olaffson (Eggert) Reise giennem, Island. Sorö, 1772.

LEPIDOPTERA.
L. phalænæ.
,, *maxima.*
,, *fluctuata.*
,, *geometra.*
,, *tota aurea.*

Again, in a work by R. Mohr, 1786, folios 90-91, under the head "Lepidoptera," we have—

L. phalænæ.
,, *graminis.*
,, *betularia.*
,, *olivacea.*
,, *lucerina.*
,, *vaccinii.*
,, *fluctuata.*
,, *pratella*, &c., &c.,

all of which are named as butterflies of Iceland.

Mr. McLachlan is a very high authority, and not at all likely to assert as a fact that there are *now* "no butterflies in Iceland," unless it were true.

The only possible way in which these perfectly opposite authorities can be reconciled (unless we throw aside those of a hundred years ago as worthless), is to suppose that in the interval the butterflies and their larvæ have been destroyed—not an impossible circumstance in Iceland, which has been almost, if not wholly, covered with poisonous volcanic ashes from time to time.

JOHN RAE

Kensington, January 18

The Great Pyramid

I HAVE been reading in Mr. Piazzi Smyth's book on this subject ("Our Inheritance," &c.). From the measurements made or cited by the author it appears tolerably clear that if the vertical height of the pyramid, as originally built, be taken as 1·, the total length of the four base lines will be twice 3·14159, &c., the number which expresses the circumference of a circle whose diameter is 1. At first sight this statement seems startling, but I think it may readily be acceded to, and that neither Mr. P. Smyth nor anyone need believe that by inspiration or otherwise, the architect knew the above relation of diameter to circumference, or was a circle-squarer in any special sense. I conceive the architect to have done something like the following:—Deciding first upon the vertical height of his intended pyramid, he took a cord, equal in length to that vertical height, and with it as a radius described a circle on level ground. Along the circumference of this circle he laid another cord, the ends of which met and were fastened together. The circle being thus formed, he drove four pegs, at equal distances inside the cord, so as to stretch it out into a square. The square thus formed gave the lines for the base of the pyramid; and it is obvious that thus the ratio of diameter to circumference would necessarily be built into the pyramid, however ignorant the architect might be. Working drawings (actual size) of surfaces, angles, chambers, passages, and other things would easily be laid out on the ground. The dimensions of the so-called King's chamber, and of a coffer or stone chest therein, which appear to involve the above ratio of 1 to 3·14159, &c., were, I think, arrived at by a somewhat similar process of construction.

Now as to the religious aspect of the case and an easy bit of "development." A cone is a well-known ancient religious symbol (of the kind denounced by Mr. P. Smyth as unclean), and no doubt cones had been erected before the time of Cheops, and had their meaning and uses. Probably they were first made of earth, and the circular base would no doubt be set out by a cord, as above described. Cheops, by his architect, squared the circular base, getting thereby lines much better adapted to stone work, whilst still keeping the old sacred emblem, though in a developed form. It may, I believe, be traced down to many modern forms not often suspected of bearing any relation to it.

Belper, January 17 J. G. JACKSON

Acoustical Effects of Atmospheric Pressure

ON tapping an ordinary bell-jar receiver after exhaustion, the following was noticed. The note derived from percussion after exhaustion was sensibly of a higher grade than that obtained from the glass containing air. On gradually letting the air in, the note sank directly as the amount of air so introduced. We conclude that the phenomena here recorded are connected with the atmospheric pressure, and that the note yielded is a function of the atmospheric pressure. Can any of your readers suggest a method for the investigation of the observed facts, if no investigations have been before made on the subject.

Rugby, January 19 G. RAYLEIGH VICARS

TRANSATLANTIC LONGITUDES[1]

IT will be remembered that a preliminary account of the results of the transatlantic longitude determination of 1872 was published in Vol. xxii. of the *Proceedings* of the American Association for the Advancement of Science. We have now received the final report of Mr. Hilgard, which embodies not only the results, but also the observations, and which sets forth concisely the manner in which the former were deduced from the latter.

The importance of fixing with the greatest precision achievable, the longitude of some point in the coast survey triangulation with reference to Greenwich, led the U.S. Government promptly to make use of the means afforded by the completion of the Atlantic telegraph cable from Ireland to Newfoundland.

The first telegraphic longitude determination through it, made under the direction of Dr. B. A. Gould, in 1866, although it surpassed in exactness all results obtained by different methods was subject to a small but indeterminate correction, the "personal equation" between the American and the standard Greenwich observer.

Use was therefore made of the French cable in 1870 to make another determination under different circumstances, and under the charge of Mr. Dean the longitude difference between Brest and Cambridge, U.S., as before, was obtained; but as at that time no cable was in operation between Brest and England, the connecting link, Brest-Greenwich, remained undetermined until 1872, when Mr. Hilgard took charge of the work necessary to supply this deficiency, and since the opportunity was afforded, to repeat the Transatlantic determination. This time an intermediate station, St. Pierre, on the American side, was introduced, thus varying still more the conditions under which this third determination was made.

The general plan of operations was to unite at Brest time signals from St. Pierre, Greenwich, and Paris. The co-operation at the last-named stations of the Astronomer-Royal, Sir G. B. Airy, and of M. Delaunay, and the generosity of the telegraph companies, enabled Mr. Hilgard to finish the work successfully in September of that year.

We can only advert briefly to one or two points of interest. The accordance of the results appears to have been due in a great measure to the attention given to the accurate determination of the relative personal errors of the observers, which gave also indirectly the "personal equation" correction, lacking in the longitude determination of 1866.

Incidentally, the "wave-time" of the cable signals was deduced, and on the assumption of equality in time in either direction, the resulting wave-time from Brest to St. Pierre, through a length of cable equal to 2,979 statute miles, is given as 0s.·351 ± s.·003.

The final results are given as follows, and the author remarks "that the close agreement of the three independent determinations made in different years is no less surprising than it is satisfactory." Even if we assume, as Mr. Hilgard evidently does, the identity of the results as accidental within the limits of the probable errors assigned, the determination must be characterised as being of the highest order of precision.

Longitude of Cambridge (Harvard College Observatory dome) west of Greenwich (meridian):—

	h.	m.	s.	s.
1866	4	44	30·99 ±	0·10
1870			30·98 ±	0·06
1872			30·98 ±	0·04
Mean	4	44	30·98 ±	0·04

Referring this mean value to Paris (meridian of France) we have :—

Cambridge—Paris .. 4h. 53m. 51s·95 ± 0s.·06

These results, combined with elaborate determinations of the longitude difference, Washington-Cambridge, give :—

	h.	m.	
Washington (Naval Observatory) —Greenwich	5	8	12·09 ± 0·05
Washington (Naval Observatory) —Paris	5	17	33·06 ± 0·07

We may, therefore, consider the geographical position of the Washington Observatory as one of the best determined in reference to others.

One of the incidental but highly important results of this expedition is the longitude difference Greenwich-Paris, the accuracy of which was checked by the conditions involved in the closing of the longitude triangle Greenwich-Paris-Brest. The result, 9m. 20s.·97 must now supersede the value obtained by Mr. Leverrier in 1854, which it exceeds by nearly half a second.

ANTOINE CÉSAR BECQUEREL

IT is with regret that we record the death of the noted French physicist, Prof. Becquerel, which occurred on January 18, in Paris. Antoine César Becquerel was born at Châtillon-sur-Loing, in the Loiret department, March 8, 1788. After completing a course in the Paris Polytechnic, he entered, in 1808, the Imperial Engineer Corps. It was no time of idleness for young officers, and he was shortly in active service, taking part in the entire Spanish campaign under General Luchet. Here he was present at the sieges of Torbosa, Tarragona, Lagonte, and Valencia, and manifested such marked abilities that in 1812 he returned to Paris to receive the rank of captain, and be presented with the Cross of Chevalier of the Legion of Honour, from Napoleon's own hands. In the following year he was sent by the Emperor to complete the fortifications on the German frontier. At the fall of the empire, in 1815, he resigned his position as chief of battalion in the Engineer Corps, and devoted himself exclusively to physical and chemical research, accepting a position as teacher in the Musée d'Histoire Naturelle, of Paris. In 1837 he was made professor in this institution and occupied this position up to the time of his death. Shortly after entering upon his scientific career he commenced the remarkable series of investigations in electricity and magnetism which have been uninterruptedly continued during the past half-century, and have linked his name closely with every branch of these two leading departments of physics. In thermo-electricity Becquerel carried out a large number of experiments on the currents caused by heating both a single metal and two metals in contact, and formulated the well-known thermo-electric series, bismuth, platinum, lead, tin, gold, silver, copper, zinc, iron, and antimony. In his studies on atmospheric electricity he proved that the water of the ocean and the solid crust of the earth are in opposite electrical conditions, a fact which explains the positive state of the air immediately above the sea, while at a distance from the ocean the positive change is noticeable only at a certain height above the earth. The physiological effects of the electric current formed likewise the subject of numerous observations, and by means of delicate apparatus he was able to demonstrate the development of minute currents by the various operations of life, the movement of the muscles, &c. In view of the purely chemical character of these operations these observations harmonised perfectly with the theory which he advanced that electric currents were produced by all chemical unions and decompositions.

---

[1] Final Report on the Determination of 1872, with a Review of Previous Determinations. By J. E. Hilgard. From the United States Coast Survey Report for 1874

The effects of electricity on the colours of flowers, he showed to consist chiefly in a mechanical bursting of the cells containing colouring matter, and not in a chemical change. The conductive powers of a number of elements and compounds for the electric current, as well as the thermal phenomena in bad conductors, formed likewise the subject of numerous investigations. In magnetism Becquerel's researches were confined chiefly to the demonstration of the ability of all bodies to be magnetised, and to the phenomena of terrestrial magnetism. His favourite field of discovery, and that in which he obtained the most brilliant results, was electro-chemical action; in the variety and value of his contributions in this department he is certainly surpassed by no other physicist, while he was the first to grasp and sum together the scattered observations, and fairly mould them into a science. In 1834 he observed the deposition of metal on the negative electrode when the two poles of a pile were introduced into solutions of the salts of various metals. Shortly after he discovered that by using feeble currents the metal could be deposited very evenly and equally on the surface of the electrode, and that the two solutions required for the purpose could be kept from mingling by the use of gold-beater's skin or animal membranes, without hindering the current. These facts were at once made use of by De la Rive, of Geneva, who based on them his technical process of gilding in 1840. Although not the first to make the practical application of his discoveries, Becquerel rapidly improved the methods derived from them, and contributed in swift succession an enormous number of facts which serve as the fundamental principles of the art of galvano-plastic. These are to be found in a compact state in Smee's Elements of Electro-metallurgy. Becquerel's famous *Oxygen-circuit*, discovered at this time, made his name known at once to a large circle, on account of its simple, practical quantities. It consists of a glass tube covered at one end with linen, which supports a layer of kaolin, and designed for the solution of the metallic salt to be reduced. This is placed in a vessel containing a dilute acid, and the object to be electro-plated is immersed in the solution after being connected by a wire with a platinum plate in the acid. The action begins instantaneously, and is both rapid and regular. Another well-known apparatus is his *depolariser*, an arrangement designed to obviate the reverse currents produced by the gaseous deposits on platinum electrodes, and consisting essentially in a continuous shifting of each of the plates to the liquid of the other, so that they have no opportunity to become polarised. The oxygen-circuit, with its gentle regular current, was used by Becquerel for the decomposition of a large variety of chemical compounds. Among the more noteworthy preparations by its action can be mentioned aluminium, silicium, beryllium, sulphur, and the various earthy and metallic phosphates. Equally extensive were the preparations of crystalline salts, notably those occurring in nature, by the action of the electric current on mixed solutions or on solutions of soluble salts in contact with insoluble substances. During the past ten years his attention has been almost exclusively devoted to the novel and remarkable electro-capillary phenomena first observed by him in 1867. These can be observed in their simplest form when a cracked test-tube containing a solution of cupric sulphate, for example, is immersed in a solution of sodic sulphide. A deposition of metallic copper takes place at once on the crack. This elementary fact has been elaborated in a variety of directions with numerous solutions, and the laws regulating the development of electric currents by capillary action partially enunciated. The study of these phenomena is, however, still in its infancy. Becquerel regarded them as explanatory of the deposition of metals in veins in the rocks and of many physiological reactions taking place in the vegetable and animal tissues. A very detailed account of the experiments is to be found in vol. xxxvi. of the *Mémoires de l'Institut.*

Despite his manifold experimental investigations, Becquerel was an indefatigable author, and contributed a most valuable series of standard works to the physical literature of the past forty years. In the seven volumes of his "Traité expérimental de l'Électricité et du Magnétisme, et de leurs Phénomènes naturels," 1834-40, he presented these two sciences with a completeness and systematic arrangement which has been hitherto wanting in physical literature. This work was followed by "Éléments d'Électro-Chimie appliquée aux Sciences naturelles et aux Arts," 1843; "Traité de Physique considérée dans ses Rapports avec la Chimie," 1844, 2 vols.; "Éléments de Physique terrestre et de Météorologie," 1847; "Traité de l'Électricité et du Magnétisme; leurs Applications aux Sciences physiques, aux Arts, et à l'Industrie," 1856, 3 vols.; Résumé de l'Histoire de l'Électricité et du Magnétisme," 1858; and "Des Forces physico-chimiques et de leur Interprétation dans la Production des Phénomènes naturels," 1875.

In 1829 Becquerel was elected a member of the French Academy, and received in 1874 the Medaille Cinquantenaire, although he had been but forty-five years a member. His scientific communications are to be found in the *Comptes Rendus* of the Academy and in the *Annales de Chimie et Physique*. The Royal Society elected him as a corresponding member a number of years ago, and he was one of the three French *savants* who have been recipients of the Copley Medal. In 1865 Napoleon III. decorated him with the Cross of Commander of the Legion of Honour.

Prof. Becquerel leaves behind him a son, Edmond Becquerel, Professor of Physics in the Conservatoire des Arts et Métiers, who has assisted his father for a long series of years in the compilation of his numerous works, and whose researches in electricity fairly rival those of the latter. The funeral ceremonies took place on Monday in the church of St. Medard, at Paris.

DAVYUM[1]

ABOUT the middle of this year (1877) I succeeded in isolating a new metal belonging to the platinum group. I named it Davyum, in honour of Sir Humphry Davy, the eminent English chemist.

The platiniferous sand from which it has been extracted[2]

---

[1] From an article by Sergius Kern in *La Nature*.

[2] The sand treated had the following composition:—

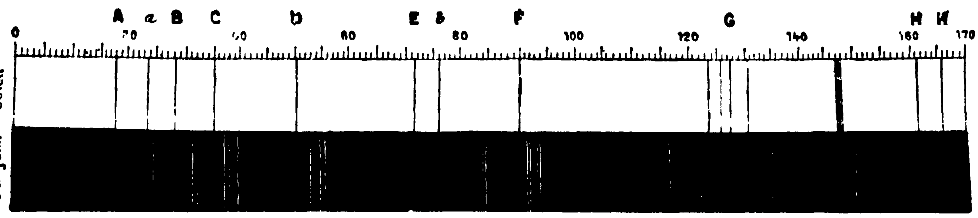
Platinum	80·03
Iridium	9·15
Rhodium	0·61
Osmium	1·35
Palladium	1·20
Iron	6·45
Ruthenium	0·28
Copper	1·02
	100·09

was treated, for the separation of the metal, by the analytical method of Prof. Bunsen. The mother-liquor obtained after the separation of the rhodium and iridium was heated with an excess of chloride of ammonium and nitrate of ammonium. A dark red precipitate was obtained after calcination at red heat. It yielded a greyish mass resembling spongy platinum. The ingot resulting from 600 grammes of mineral weighed 0·27 kil.

The metal was dissolved in aqua regia, in order to examine the action of different reagents on the solution. Potash gave a clear yellow precipitate of the hydrate of davyum, which is easily attacked by acids, even by acetic acid. The hydrate of davyum dissolved in nitric acid gave a brownish mass of nitrate of davyum; by calcining this salt a black product is obtained, which is probably the monoxide.

The chloride of davyum, dissolved in a solution of potassic cyanide, gave, by gently evaporating the solution, beautiful crystals of a double cyanide of davyum and potassium. In this salt the potassium may be replaced by several metallic elements. The cyanodavic acid is very unstable; it is isolated by passing a current of sulphuretted hydrogen through a solution of the double cyanide of lead and davyum. Sulphuretted hydrogen produces, in the acid solutions of davyum, a precipitate of sulphide of davyum, which is easily attacked by the alkaline sulphides, yielding probably a series of sulpho salts.

A concentrated solution of chloride of davyum yields, with potassic sulpho-cyanide, a red precipitate, and when gently cooled, produces large red crystals. If the same precipitate is calcined the sulpho-cyanide of davyum takes the form of a black powder. These reactions show that this salt is allotropic.



Spectrum of davyum according to the data of Sergius Kern.

The chloride of davyum is very soluble in water, alcohol, or ether; the crystals of this salt are not deliquescent. The calcined salt gives the monoxide as a residue. Chloride of davyum forms double salts with the chlorides of potassium and ammonium. They are insoluble in water and very soluble in absolute alcohol. The double salt of sodium and davyum is almost insoluble in water and alcohol; this reaction is very characteristic, because many sodic salts of the platinum group are very soluble in water.

This chloride of davyum is the only one which exists, as the second product, containing more chlorine, is decomposed during the evaporation of the solution, disengaging chlorine.

I have made some new researches on the density of melted davyum; three experiments gave the following numbers:—9,383 9,387, 9,392 at 24°. These results agree very sensibly with those of my first researches; the density of davyum given in my first note to the Academy being 9.385 at 25°.

M. Alexejeff has undertaken the determination of the equivalent of davyum; but as the quantity of davyum which I possess is very small, exact researches are difficult. Preliminary experiments have shown that the equivalent is greater than 100, and probably about 150-154.

Some new platiniferous sands, which are to be placed at our disposal, will yield a sufficient quantity of the new metal for additional experiments. We hope to have in time nearly 1·2 gr. of davyum.

Finally I have investigated the spectrum of davyum by vaporising the metal in powder between the carbons of the electric lamp. The spectroscope at my disposal is not powerful enough to show precisely all the secondary lines. This is why I have only indicated the principal lines easily visible in my spectroscope.[1]

THE GREAT DETONATING METEOR OF NOVEMBER 23, 1877

HAVING fully discussed the whole of the accounts of the great meteor that have reached me, consisting of some ninety direct communications and forty or fifty newspaper cuttings, I have the pleasure to forward to NATURE a condensed description of it.

The points of most importance to be determined are—1. The true orbit which is obtained from a knowledge of the radiant and velocity of motion. 2. The height at which it first became luminous, as our knowledge of the real extent of the earth's atmosphere depends exclusively upon such determinations. 3. The height at which it exploded and came to an end. That this last is connected with the physical condition and constitution of the body cannot be doubted. The brightness of meteors seems always to depend upon the distance they penetrate into the air. Generally, when they get below 30 or 40 miles, they are very remarkable.

The Greenwich mean time was 8h. 24m. 30s. on November 23.

There are but few descriptions of the path of the great meteor in question from which to derive the radiant point. Five of the fully-described tracks meet almost exactly in R.A. 62°, N.P.D. 69°. The others tend to support this position rather than to alter it, but many are, as is usual, extremely wild, passing 20°, and even 30° from it. To an observer situated near the middle of the north coast of Wales, this radiant would bear south 74° E., at altitude 37°.

The meteor first came visible to Mr. T. B. Barkas, at Newcastle-on-Tyne, to another observer at Tynemouth, to the Rev. G. Iliff, at Sunderland, and Mr. E. Pikard, at York, at the great height of 96 statute miles. The observers agree very closely. It is probable, of course, that had any one been actually looking in the right direction, it might have been seen a little earlier when it was still higher. A height exceeding 90 miles is certain. The meteor was then vertically over a point 13 miles north of Derby, and its appearance was that of an ordinary shooting star. Descending in the air at the inclination of 39° to the surface of the earth, when 48 miles exactly over Liverpool, it became intensely brilliant, so suddenly, that many observers speak of this as the first explosion.

It was at this instant that it attracted universal attention. People as far distant as Essex, Roscommon, Edinburgh, Bristol, and Queenstown, 200 miles from it, describe it as being nearly as large as the full moon and greatly exceeding it in brilliancy. An observer at Ashby-de-la-Zouch first noticed his shadow, and those of neighbouring trees thrown *towards* the moon, then shining brilliantly in the east. Persons much nearer the scene, sitting in rooms with the blinds down, were frightened by the flood of light that suddenly found its way in. The meteor exploded with great violence at the height of 14 miles over the Irish Sea, 20 miles N.N.W. (true) of Llandudno. The total length of path was 135 miles, which was traversed in about 8 seconds of time, or with a velocity of 17½ miles per second, as determined from twenty-three estimations of its duration.

---

[1] *Comptes Rendus* and *Chemical News*.

The streak left in the air extended for 40 miles along the track, and was not less than 2,000 feet in diameter.

The violence of the explosion was such, that at Bangor, Beaumaris, Conway, and Llandudno, doors and windows rattled, and people ran out to see what was the matter. As far as Chester the sound resembled " thunder not very far distant," or " a salvo of artillery."

It is a fact worthy of thoughtful consideration that the body which was capable of producing this convulsion, probably exceeding the discharge of the 81-ton gun in the proportion of a hundred to one, was converted into impalpable powder in eight seconds of time, merely by the rapidity of its transmission through very attenuated air. After the explosion nothing remained but dully incandescent dust or ashes, which slowly fell a short distance *vertically* downwards. That is to say, there was not one remnant sufficiently heavy to continue in the same direction, or to retain the original velocity, because such a remnant would have been visible itself as a bright meteor. A momentum which, estimated in foot-tons, would reach some enormous figure, was instantaneously reduced to nothing, or, rather, converted into atmospheric waves—and dust !

The exact position and height of the explosion is fixed by the singular observation of Mr. Petty, at Llandudno (NATURE, vol. xvii. p. 183), who did not even see the meteor itself, but its light on the hearthrug coming through a chink in the blind.

Mr. J. Ismay, the superintendent of telegraphs at Liverpool, who observed the explosion from the beach at Llandudno, measured the sound-interval, and found it between 2 min. and 2 min. 15 secs. From the spot where I have assumed the explosion took place to his position is 25 miles, which sound would traverse in two minutes exactly.

The orbit deduced from the apparent position of the radiant point is—

$$i = 0$$
$$\pi = 153^\circ$$
$$q = \cdot 47$$

Motion direct.

The relative velocity obtained by assuming a parabolic orbit is 19 miles per second, agreeing very closely with that found by observation.

If the longitude of the radiant be diminished 3° or 4°, the orbit is so far modified as to almost coincide with that of the comet of 1702. The comet was not very well observed. The meteor belonged to the well-known shower of *Taurids*, first discovered by Mr. R. P. Greg, encountered by the earth with great regularity about November 21–23. In 1877 it appears to have been very prolific of bright and of detonating meteors.

G. L. TUPMAN

OUR ASTRONOMICAL COLUMN

THE COMETS OF 1618.—The year 1618 presented a phenomenon which is perhaps unique in the history of the appearances of comets, two of these bodies having been conspicuously visible at the same time in certain parts of he earth, and for several days, at least, in the same quarter of the heavens, with trains of thirty or forty degrees in length, and upwards. Cometographers previous to Pingré had been much exercised with reference to the comets of this year ; Comiers, in " La Nature et Prestige des Comètes," had supposed that six comets in all were observed in 1618 ; this number was reduced by Pingré to three, which appears to have been beyond doubt the correct number, though another cometographer, Struyck, disputed the distinctness of Pingré's second.

The first comet was discovered at Caschau, in Hungary, on August 25, and two days later by Kepler, at Lintz, where it rose in the morning about three o'clock, with a tail directed towards the west. Kepler observed it on several occasions, and for the last time on the morning of September 25, and from his rough indications of its positions Pingré calculated the elements which figure in our catalogues, and which it will be found represent the track of the comet pretty nearly ; there can be no confusion between this object and the second or third comets of the year.

The third comet, as Pingré remarks, " eut autant d'observateurs qu'il y avoit alors d'astronomes en Europe." It was first seen in Europe in the last days of November, and was observed by Cysat at Ingoldstat till January 21, he having used optical aid, though other observers lost it at the beginning of the month, or even earlier. The elements, first calculated by Halley, were more accurately investigated by Bessel, whose orbit, published in 1805, agrees with the observations as closely as the errors, with which they are obviously affected, will allow. There is no difficulty, therefore, in fixing upon the position of the third comet, with sufficient approximation in the month of November previous to its discovery in Europe.

It appears to have been one of the finest comets of the seventeenth century, apparently hardly exceeded in the imposing character of its appearance by the celebrated comet of 1680. The tail gradually increased in length until, on the morning of December 10, the Danish astronomer, Longomontanus, estimated its extent at 104°, with marked coruscations.

The second comet of 1618, according to Pingré, to which these remarks are intended more particularly to refer, was discovered in Silesia, and also at Rome, on the morning of November 11, as Kepler tells us (*De Cometis lib. I.*). The nucleus was lost in the twilight, but the tail was visible from 4h. 20m. to 6h. 40m. at Rome. On the following mornings the tail was seen at other places in Europe, and by Kepler himself at Lintz, at 5h. 30m. A.M. on November 20 ; he then describes it as a train of milky-white light, passing below the stars in the quadrilateral of Corvus, and reaching the extremity of Crater. He saw this train for the last time on the morning of November 29, when " inter atras nubes et ventos vehementes, cum campi essent picti nivula, apparuit tamen tractus iste secundi cometæ, sed valde dilutus nec æquans albedinem nubium a luna illuminatarum." This was at 5 A.M., and an hour and a half later, the clouds having somewhat dispersed, he obtained his first view of the third comet, which was then in longitude 221°, with between 9° and 10° north latitude. Thus we see that Kepler saw both comets on the same morning, though he failed to detect the nucleus of the second in the strong twilight ; and it may be added that Blancanus, at Parma, had similar experience.

In more southern latitudes the second comet was pretty favourably situated for observation, and its nucleus was observed. Figueroes, ambassador of Spain, at Ispahan, and the Jesuits at Goa, saw both comets simultaneously, and determined positions of the nucleus of the second. Riccioli mentions that Father Kirwitzer, an Austrian, was sent out to China, and died at Macao in 1626, adding that he wrote of observations made in India on the comets of 1618.

In a communication to Baron de Zach early in 1821, Olbers states that Brandes had sent him a work by this Father Kirwitzer, which it appeared had become very scarce, containing observations of the second comet of 1618, but so disfigured by faults either in copying or printing, that he had found it impossible to deduce from them a tolerable orbit. According to these observations "la comète sautille d'un jour à l'autre ça et là dans le ciel, tantôt en avant, tantôt en arrière, de sorte qu'à peine peut-on reconnaître quelle a été la vraie direction de son mouvement." Kirwitzer, who had observed the comet from November 14, reports that on November 26 he was joined in the observations by Father Schall, and Olbers drew attention to the fact that in Zach's *Monatliche Correspondenz*, vol. xxviii., it had been stated that fourteen volumes of Schall's manuscripts were in existence in the library of the Vatican, and engaged Zach to use his interest towards having them examined. This was soon after effected by Conti, but unfortunately no allusion to the second comet of 1618 was found in them, indeed these manuscripts proved so worthless, that Zach considered them "que de la poudre chinoise jetée aux yeux européens." It does not appear that a more accurate copy of the Goa observations has been found since Olbers wrote on the subject. There are two works by Kirwitzer in the British Museum, but they afford no assistance. It thus happens that there is as yet no orbit of the comet in question.

In a further note we shall briefly recapitulate other circumstances in the history of the comet, and examine one or two points in which the known elements of the third comet assist in establishing the absolute distinctness of the second, notwithstanding the idea advocated by Kepler that a comet had divided into two—and which led Pingré to say of him—*aliquando bonus dormitat Homerus.*

METEOROLOGICAL NOTES

Contribution to the Climatology of the Spanish Peninsula.—An interesting and able contribution to the climatology of the Spanish Peninsula has been made by Dr. Hellmann in a discussion of the humidity and clouds of that region, published in the Dutch *Meteorological Year-Book* for 1876, being one of the results of the author's recent prolonged meteorological tour in the Peninsula. One of the broad results arrived at is this: the small variation in the annual humidity of places on the west coasts of Europe, as contrasted with the large variation in the humidity of the east coasts of Asia, together with the striking climatic contrasts resulting therefrom is essentially, though less intensely, reproduced in the climates of the Peninsula of the west bordering the Atlantic as contrasted with those of the east washed by the Mediterranean. As regards the relative humidity of the air, the climate is moister in May than it is immediately before and after, and it is interesting to observe that thunderstorms, rain, and cumulus, cirro-cumulus, and cumulo-stratus clouds show an increase in May as compared with March and April on the one hand, and June and July on the other. The annual variation in the relative humidity increases from about four to nine per cent. on the coasts, to about forty per cent. at such inland places as Madrid and Campo Maio. Those who are familiar with the weather-maps of Europe are aware how often atmospheric pressure is so distributed as to give rise to winds blowing outwards from the Peninsula to the ocean in all directions, being easterly on the west coast, southerly on the north, westerly on the east, and northerly on the south. They are everywhere dry winds, and are known in the various provinces as the *Terral*, or land-wind. The desert-wind of the Spanish Mediterranean coast is the *Leveche*, and not the *Solano*, as it is almost universally stated to be by non-Spanish writers. The Solano is, as its name implies, a simple east wind which blows everywhere over the east coasts, and is a rain-bringing wind, but in no sense a desert-wind, malignant and prostrating in its effects. The true desert-wind is known by the name of the Leveche, which is usually loaded with fine sand and dust, and is hot and stifling, is productive of violent headaches, and prostrates even the most robust with a feeling as if every member of the body were oppressed under a load of lead. Dr. Hellmann describes the effects of the passage of one over a vineyard in August, 1876, the appearance being as if a scorching flame had passed over it. The Leveche is felt on the coast only from Cabo de Nao, to Cabo de Gata in the south, and in a less severe form as far as Malaga; but it extends inland no farther than from forty to fifty miles.

Climatology of the Fiji Islands.—A valuable contribution to this subject from data collected by the Meteorological Office has appeared in the *Quarterly Journal* of the Meteorological Society for July, 1877. From the position of the Fiji Islands in the South Pacific, the climate is strictly tropical, the year being divided into a hot moist season, extending from November to April, and a cool dry season from May to October. The prevailing winds are S.E. and E., but during the hot season, particularly from January to March, N.E. winds prevail. These N.E. winds are, in Mr. Strachan's opinion, probably due to the heated land of the large island, Viti Levu, giving rise to a wind of aspiration. The annual rainfall on an average of six years was 110 inches. The heaviest falls occur in the summer months of January, February, and March, when thunderstorms are frequent, and in the same months hurricanes occur, though frequently several years pass in succession without the occurrence of any hurricane. In the cool season the rainfall, though considerable, is reduced in amount and frequency, and in all seasons there is a considerable difference as regards moisture and rainfall between the windward and lee sides of the different islands, the effect being strikingly shown by the difference of vegetation. The working out of this question of the distribution of the rainfall by such a multiplication of gauges over the islands as has been so successfully done in the Mauritius and Barbadoes, is most desirable from the scientific and practical importance of the subject. The mean annual temperature is about 77°·5, and the difference between the hottest and the coldest months scarcely reaches 5°. In the wet season atmospheric pressure is about 29·870 inches, and vapour tension 0·860 inch, but in the dry season 30·020 inches, and 0·700 inch, thus showing considerable variation through the year in the pressure and vapour tension of a climate characterised by comparatively so little variation as that of Fiji.

Extension of Volunteer Weather Service in the United States.—We are greatly gratified to see that the marked success which has attended the volunteer weather service in the State of Iowa, so vigorously prosecuted by Dr. Hinrichs, and which now numbers about 100 observers, is leading other states to adopt a similar system. Prof. Francis E. Nipher, of the Washington University of St. Louis, has already secured the services of fifty-five observers, chiefly in the northern and western parts of Missouri, for the regular observations, particularly of rainfall, but also, where possible, of temperature pressure and humidity; and for observations of irregularly recurring phenomena, such as storms, the aim being to collect together as full and accurate an account of the different phases of these phenomena as it is possible to make, particularly their commencement, culmination, and termination. The investigation of the climatology of the state is also to be undertaken. The observations are to be according to local time. Regular reports will be furnished to the newspaper press. The work is undertaken under the auspices of the university, and it is not intended that it supersede, as regards this State, the work of the central office at Washington (D.C.), but to supplement that work in collecting data for a more satisfactory treatment of the climatology and storms of that state. We strongly commend this scheme, and earnestly hope that Prof. Nipher will succeed in extending his network of stations till all parts of the state be adequately represented, especially since telegraphic stations everywhere are by far too few to meet the requirements of the more important and pressing problems of meteorology. We have the further satisfaction in learning that a similar weather service is contemplated in the State of Kentucky.

HIGH TEMPERATURE OF NOVEMBER LAST.—M. Brounoff, of the St. Petersburg Physical Observatory, publishes in the Russian *Golos*, December 10, an interesting note as to the unusually high temperature of St. Petersburg during November last. The mean temperature of that month was as high as 39°·4, or 10°·3 higher than the mean temperature deduced from ninety years' observations, and 4°·9 above the very high mean temperature of November observed at St. Petersburg in 1851. Throughout the month the thermometer never fell below 32°·0. It is worthy of notice that during all the other months of this year the temperature was lower than the means deduced from ninety years' observations. An unusually high temperature prevailed in November over nearly the whole of Europe and Western Siberia, except North Scotland, Southern Italy, the middle Danube, and the two shores of the Caspian. The highest above the average, 15°·7, was observed at Archangel, and the line of 9°·0 runs from the Upper Volga to Stockholm, and thence straight north. The proximate cause of such unusually high temperature was the abnormal predominance of barometrical minima with south-westerly winds, which passed over Europe during November last. Thus, the number of these minima in November has been forty-two during the last five years, whereas there occurred thirteen during November last, the one thus following the other almost without interruption.

TEMPERATURE OF VIENNA.—Among other points treated in a recent paper by Dr. Hann to the Vienna Academy, "On the Temperature of Vienna, according to a Hundred Years' Observations," is the influence of the frequency of sun-spots on the mean temperature of summer, winter, and the year. Neither in the temperatures arranged according to the separate cycles of sun-spot frequency, nor in the averages of these from all the nine cycles (1775 to 1876) is there recognisable a distinct periodicity of the heat variations, which can be connected with the period of sun-spot frequency. Placing in the individual cycles the averages of every three years' temperatures, corresponding to the minimum and maximum of the spots, opposite each other, it is found that in five cycles out of nine the minimum years have indeed a considerably greater heat than the corresponding maximum years. But in three cycles precisely the opposite is the case, and in one cycle the difference is almost *nil*. Dr. Hann further inquires whether one may with any probability draw inferences from the temperature character of one season with regard to that of the next, and the next again. He finds that if the temperature-anomaly of one season reach a considerable amount (a divergence of 1° C. or upwards), the probability that the following season will diverge in the same sense from the average value is 0·68; the probability that a very cold or warm winter will be followed by a cold or hot summer respectively, is even 0·70. On the other hand, the probability of an agreement of the temperature-anomaly of a winter with that of the previous summer is only 0·45. In his paper Dr. Hann also gives a comparison of the temperatures of the meteorological and astronomical observatories.

GEOGRAPHICAL NOTES

MR. STANLEY.—Mr. Stanley arrived in London on Tuesday. From the time that he emerged at Emboma from his ever-memorable dash into the unknown region west of Nyangwé to his arrival at Folkestone, his journey homewards has been a well-earned ovation. Everyone, from the Governor downwards, at the Cape vied in doing him honour; at Cairo the Khedive conferred upon him two of the highest orders of merit; at Rome he received the Victor Emmanuel Gold Medal of Merit, arriving too late, alas! to receive it from the hands of its donor, though it was accompanied by a sealed letter from the late King, speaking in high terms of Mr. Stanley's discoveries and his services to humanity and civilisation; Turin, Milan, and Naples sent welcomes to him; at Marseilles the Geographical Society, the Chamber of Commerce, and the Municipality presented him each with a medal; at Paris the Geographical Society fêted him in splendid style, the President of the Republic sending his representative the Minister of Public Instruction presenting him with the high honour of the palms of Officier de l'Instruction Publique, and the President of the Geographical Society telling him he should be gold medallist of the Society for 1878. We expressed confidence last week that our own Geographical Society would lead the movement in this country for giving Mr. Stanley a reception worthy of the great work he has achieved, and we rejoice to see that our confidence has been justified. The Society are to invite Mr. Stanley to dinner, and also to read a paper on his discoveries, "at St. James's Hall or elsewhere." We feel sure that St. James's Hall will be quite inadequate for the accommodation of all who will wish to see and listen to the story of one of the greatest of pioneer-explorers; so that, after all, the announcement made in the *Times* last week, that the Albert Hall was to be taken for the purpose, is likely enough to be correct. There will certainly be no difficulty in filling it. Everyone will wait with impatience the publication of Mr. Stanley's work; for although a fair idea of what he has done has been obtained from his occasional letters in the *Telegraph*, there must be many things to tell that could not be set down in the circumstances under which these letters were written.

THE MARQUIS ANTINORI.—From another telegram received by the Geographical Society at Rome, it appears that the Marquis Antinori, contrary to his first intention, does not return to Italy, but has started again with his companions on a new tour southward from Shoa. Signor Martini alone comes home with the scientific collections.

AFRICAN EXPLORATION.—Reports from Berlin state that in the budget for the current year the sum of 100,000 marks (5,000*l.*) is asked for the continuation of the exploration of Central Africa. This is considerably more than in the preceding years; the rise in the sum demanded is justified by reference to the efforts of German private societies and scientific men.

THE NORTHERN PAMIR.—The last number of the *Izvestia* of the Russian Geographical Society contains some new and valuable information on the little-known tracts of the Northern Pamir, which have hitherto been a blank on our best maps. This information has been compiled from notes taken last summer by M. Korostovtseff during his journey to the Alai Valley and the Northern Pamir highlands. The valley of Alai, visited first by M. Fedchenko, runs north-east and south-west for forty-five miles, and is from thirteen to twenty miles wide. It is inclosed between high mountains, the Kaupmann Peak reaching 25,000 feet. Forests are found only in the north-eastern part of the valley (11,000 feet above the sea) which is part of the dominions of the Khan of Kashgar, while the south-western part (8,000 feet high), watered by the Kyzyl-su River, is covered with luxurious Alpine pasturage, and therefore becomes in summer the feeding ground for immense herds of cattle belonging to the Fergana, Kashgar, Shungan, and Karateghin Kirghizes. A sandy cleft, Tash-kurgan, leads from the Alai Valley to the Pamir Highlands. After a journey of forty-five miles along this cleft, and after having crossed the Kyzyl-art Pass, 14,017 feet high, M. Korostovtseff reached the salt-lake, Kara-kul, twenty-seven miles long and twelve miles wide, 13,194 feet above the sea-level. Its sandy banks are quite bare, and the surrounding stony hills bear no traces of vegetation; it is only close by the deep-blue waters of the lake that the traveller discovers here and there a low and dry bush. Thence M. Korostovtseff turned south-east, entered the cleft Alabaital, and reached, by a gentle slope, the pass of the same name, 15,314 feet high, whence he had to descend on the very steep southern slope, to the valley of the Chan-su River, quite bare and covered with snow-white deposits of salt. The valley of a rivulet, Uz-bel, tributary of Chansu—a sandy desert twenty miles long—and the Uz-bel Pass, 15,195 feet high, were followed east to reach the valley of Sary-kol, 14,300 feet above the sea-level, and covered with a very scarce vegetation; here some small rivulets give rise to the Kashgar-daria River. Thus the general characters of the northern part of the Pamir table-land are high valleys, flat, open, bare, and sandy, never descending below some 13,000 feet, with blue salt lakes and salt deposits on their dry bottom; relatively low mountains, the passes between which are only some 1,000 or 2,000 feet above the bottom of the valleys, the peaks being covered with perpetual snow when they exceed an altitude of 15,000 or 16,000 feet; no inhabitants, and a very scarce vegetation. Such is the hitherto mysterious "roof of the world" (Pamir). From Sary-kol M. Korostovtseff was compelled to return. He died a short time after his return, without being able to publish the results of his most interesting journey or describe the valuable collections he obtained.

THE "NERTHUS" OF TACITUS.—Dr. Michelsen, of Schleswig, has just published a pamphlet in which he discusses that remarkable and often-mentioned Nerthus-island, which, according to the description of Tacitus, with its sacred lake and forest, formed the centre of a divine service of seven closely connected communities. Formerly the island of Rugen, or the so-called "Land Oldenburg," was thought to be the island in question. Dr. Michelsen, however, points out that the island of Alsen is the one meant by Tacitus. He states that the name signifies "sanctuary" or "temple-island," and that the sacred lake and forest still exist in the north-west of Norburg on the Alsensund, under the names of "Hellewith and Hellesö" (*heilige Wald und heilige See*—holy wood and holy sea). The inhabitants of that district still call the village of Hellewith, situated near the forest, Hellod (*heiliges Eigen*—holy own); and in the existing remains of the old forest there is a well-preserved sacrificial altar consisting of enormous blocks of granite. Dr. Michelsen gives a number of other interesting proofs for the correctness of his conjecture, and also remarks that he has partly discovered the names of the seven Nerthus people in villages of the Sundewitt district.

VENEZUELA.—In the January session of the Berlin Geographical Society, Dr. Sachs gave a description of his recent journey to Venezuela, for the purpose of studying the gymnotus in its native haunts. Humboldt's sketch of the Llanos was completed and corrected in some points. This great plain, formerly an inland sea, is 600 feet above the sea in its upper part, and but 200 in its lower part, a difference which accounts for the fact that the grass, but 1 to 2 feet in height in the upper portion, rises above the head of the river in the lower region. The decrease in the number of cattle on the Llanos of late years has led to a rapid extension of the arboreal growth. The Llaneros are a peculiar people, arising from a mixture of the white, red, and black races, and standing on a low grade of civilisation, their religion consisting in the adoration of a few saints, and marriages being rare. Humboldt's familiar description of the capture of the electric eel, by driving horses into the streams frequented by it, as the customary method in the land, is regarded as resting on an error. No one in the region was acquainted with it, and it was found impracticable to carry out. The scientific results of Dr. Sach's observations will be published shortly.

THE INDUS.—The course of the Indus river from the point where it leaves Cashmere down to where it enters English territory, about 120 miles below Darband, has recently been explored in detail by a Punjaub surveyor, and our geographical knowledge of the river has thus been considerably augmented, while valuable topographical material has been obtained. Of course Capt. Carter had previously determined, in a general way, the course of the river in the districts named, by his trigonometrical measurements of the heights of the mountain summits on both banks of the Indus.

NEW GUINEA.—Dr. E. T. Hamy, in the just issued November part of the *Bulletin* of the Paris Geographical Society, describes in considerable detail the results of his examination of an old map of New Guinea, for the purpose of showing how much had been done for its discovery by the Spanish navigators of the sixteenth and seventeenth centuries (1528–1606). The map, which serves as the basis of Dr. Hamy's paper, is contained in the atlas of Pierre Martier, published at Amsterdam in 1700. The data for this and other maps in the atlas had been collected by Frémont d'Ablancourt while in Portugal, and the many names on New Guinea would show that by the sixteenth century its coasts had been pretty well explored all round, though its shape is very inaccurately laid down.

NOTES

WE give some account to-day of the life and work of the late M. Becquerel, and next week we hope to do the same for M. Regnault, who died two days after M. Becquerel, in his 68th year. M. Victor Regnault was born at Aix-la-Chapelle, in 1810. He was Professor of Physics in the College of France, and of Chemistry in the Polytechnic School; he also held for some time the Directorship of the Porcelain Manufactory of Sèvres. His researches in the several branches of physics and chemistry published in the *Memoirs* of the French Academy of Sciences, and many other scientific journals, are numerous, and of the greatest value. Of these perhaps his publications on the expansion of elastic fluids, the determination of the densities of gases, the measurement of temperatures, and the determinations of the specific heats of liquids, solids, and gases, are the most important, and have brought his name most prominently before the world. He has also written many valuable papers on physiological questions. M. Regnault was elected a member of the Academy of Sciences in 1840, and in 1850 was created an officer of the Legion of Honour.

THE Council of the Royal Society of Edinburgh have awarded the Neill medal to Dr. Ramsay Traquair, for his paper on the Structure and Affinities of *Tristichopteris alatus*, Egerton, being one of an important series of contributions to the knowledge of the structure of recent and fossil fishes.

WE are informed that the Pennsylvania Railway Company are disposed to grant very favourable terms to any European astronomers who, in their private capacity, may wish to go to America to observe the approaching eclipse of the sun. It is stated that for less than half the usual fares astronomers will be conveyed from New York, Washington, or Baltimore to Denver. We hope, however, to be able in an early number to publish definite information on the matter.

THE German Military Department, always on the watch to make use of the latest scientific discoveries, has naturally devoted its attention at once to the telephone. In the last number of the *Militair Wochenblatt* we notice a report on the practicability of its use in warfare for maintaining communication with pickets and outlying posts. The experiments were carried out at a temperature of $-3°$ C., and during a violent wind, and showed most conclusively its availability for the purposes in question.

IT is gratifying to know that at last Cleopatra's Needle has safely reached the Thames. It is proposed to moor the ingeniously-constructed vessel containing the obelisk at a convenient part of the Thames embankment for some days, to enable the public to inspect it.

THE lately formed society for the protection of the interests of chemical manufactures in Germany, begins with the present year the publication, at Berlin, of a monthly organ entitled *Die chemische Industrie*, under the editorship of Dr. Emil Jacobsen. It is intended to make it a complete record of everything of interest in the department of technical chemistry.

THE Academy of Sciences will hold its anniversary meeting next Monday, when M. Bertrand will deliver an *éloge* of Lame, a member of the Academy of Sciences and a physicist, who died twenty years ago. He had travelled in Russia like Becquerel, but not as an officer belonging to an invading force. He had been appointed by the Russian Government to establish the Military School of Odessa.

THE second part of Signor Mantegazza's studies on the Ethnology of New Guinea is published in the December number of his *Archivio*, illustrated by a number of plates.

A GEOGRAPHICAL Society has been formed at Metz, based on the model of those in other German cities.

THE German Patent Office reports that it has received during the past year 6,424 applications, a larger number than any other country can boast of except the United States.

THE Association for the Improvement of Geometrical Teaching held its annual meeting at University College, Gower Street, on Friday, January 11, and at this meeting, in addition to proceeding with the work already taken in hand, it was resolved that sub-committees should be appointed to draw up syllabuses of solid geometry and of higher plane geometry, and also that the Association should take into consideration the subject of geometrical conics, with a view to expressing its opinion on the best order of teaching it. The president (Dr. Hirst, F.R.S.) delivered an address, and subsequently tendered his resignation of the presidentship on the ground of the pressing nature of his other duties; the Rev. E. F. MacCarthy, one of the secretaries, also was obliged, for a like reason, to resign his office. The vacancies were filled up by the election of Mr. R. B. Hayward, F.R.S., as president, and of Mr. R. Tucker as secretary (in conjunction with Mr. R. Levett, the principal originator of the movement). Mr. J. M. Wilson and Dr. Jones were re-elected vice-presidents. Mr. H. C. Watson, Clifton College, was elected Treasurer in the room of Mr. H. Weston Eve.

IT appears that beer is adulterated to a great extent with glycerin. An easy and exact method of its determination in this connection is wanting, and a prize of 3,000 marks has been offered by the *Verein für deutschen Gewerbfleiss* for the best solution of this problem.

THE *Deutsche ornithologische Gesellschaft* was lately requested by the Chancellor of the Empire to express its opinion on a proposed law for the protection of birds. A duly appointed commission under the presidency of Dr. Brehm, has recently presented a report on this subject, in which the contemplated law is regarded as unnecessary. There is at present, according to their information, no general diminution in the number of useful birds, and where a local disappearance has been observed, it is to be traced to the present development of the agriculture and forestry of the land, and is not due to the direct attempts of man.

THE German botanist, Regel, has discovered in the Himalayas a variety of wild onion, which he regards as the original source of our ordinary garden onion. It is called *Allium cepa sylvestre*.

BERLIN is becoming the centre of an extensive system of subterranean telegraphic lines radiating in various directions. Cables have been already laid, or are in process of being laid, on the routes Berlin-Cologne, Berlin-Frankfort, Berlin-Strassburg, Berlin-Breslau, Berlin-Königsberg, and Berlin-Hamburg and Kiel. As a glance at the map will show, the military element plays an important part in the selection of these routes. Most of the lines are buried alongside the substantial roadways which traverse the empire. The work of excavation is carried on rapidly by means of enormous portable engines which dig a trench one metre in depth and half a metre broad, lay in it the cables (generally two in number, containing each seven wires), and cover them by a continuous movement.

A DOG-FISH became entangled in the net of some French fishermen near Cape Agde lately, and after having dragged their boat about during the entire night at the rate of twelve miles an hour, was finally captured and brought to land. It measured over sixteen feet in length and weighed about 2,500 lbs. Its enormous stomach contained the head, feet, and several other portions of a mule, as well as two half-digested tunny-fish.

WE notice in the last number of the *Journal* of the Russian Chemical and Physical Societies (vol. ix. No. 9), two interesting chemical papers by M. Eltekoff, on the regularity of elimination of the elements of the haloid hydric acids from chlorates of hydro-carbonates, and on the structure of different amylenes which are found in the amylene supplied by trade.

PROF. C. HERMANAUZ, of Vienna, died recently in Japan, while engaged on a voyage round the world, chiefly for the purpose of agricultural observation.

FEW national scientific associations have grown so rapidly as the French Association for the Advancement of Science. Although but in its seventh year, we notice from the recently issued report of the secretary that the number of the members is already nearly 2,400. In this short time the association has accumulated a capital of 223,000 francs, and has granted 26,000 francs to various scientific objects. Each member pays annually 20 francs, and receives a handsome copy of the report. The last issued (for the Session of 1876) forms a bulky volume of 1,200 pages, illustrated by seventeen well-executed plates. According to the statutes, Paris is excluded from the place of session, on much the same ground that London is never chosen by the British Association. The present year forms, however, an exception, on account of the Exhibition, and Paris will welcome the Association far the first time.

IN the eighth number of the *Journal* of the Russian Chemical Society is a paper by Prof. Meorshutkin on the influence of isomerism on the formation of ethers between acids and alcohols (NATURE, vol. xvii. p. 151) (also published separately in French); a note by M. Ziloff, on the influence of the medium on the electro-dynamical induction; a paper by M. Borgmann, on thermo-electricity; and a note by M. Kraevich, on his new portable barometer, which is intended to avoid the usual boiling of mercury in barometrical tubes, and was highly approved some time ago by officers of the Russian general staff, who have had the opportunity of making use of it on travels.

M. CHIKOLEFF, who has made, at St. Petersburg, several experiments on electrical lights, by order of the Ministry of War, confirms, in the ninth number of the *Journal* of the Russian Chemical and Physical Societies, the results of the experiments of Tyndall. He observes also, that a galvano-plastic copper coating of the carbon proves to be very useful.

AT a recent lecture held at the Rudolphinum, at Vienna, before a large audience, Dr. E. Lewy proved that the human skin is completely impenetrable for the chemical contents of mineral waters, and that therefore the explanation of the effects of baths in these waters, at the numerous bathing-places, has to be sought exclusively in the domain of physics and not in that of chemistry. This important discovery annuls all common views regarding the bathing cures effected by the various mineral springs, and explains in the simplest manner that, from a chemical point of view, the action of the most different waters must be one and the same.

THE French Government has recently appointed a mixed commission of leading scientific men and engineers for the purpose of making a thorough examination into the best means of preventing the explosions of firedamp in coal-pits. Among its members are MM. Daubrée, Berthelot, Thénard, and Hébert, of the Academy of Sciences, Professors Bert, Burat, Haton de la Goupillière, Fouqué, and other well-known names. Although the French mines have suffered comparatively little in this direction, the terrible disasters in our English mines have taught the necessity of throwing about the miner's dangerous occupation the utmost safeguards at the command of modern science, and an active and thorough programme is being prepared by the Commission.

A REQUISITION has been sent to the French Ministry by the Société de Physique, asking that it should be incorporated, or "reconnue comme d'utilité publique." It is stated that a favourable reply may be expected from M. Bardoux.

AT a recent meeting of the French Physical Society, M. Duter presented magnets obtained by subjecting circular steel plates to the action of an electro-magnet terminated with a conical point applied to the centre of the disc. In these magnets the neutral line is a concentric circle of the disc, with radius $\frac{R}{\sqrt{3}}$. To study the free magnetism distributed over them, M. Duter used a small soft iron cylinder (a few centigrammes in weight), fixed in the centre to the rod of an areometer floating in water. The force of detachment of this was estimated by the weight of water which had to be let off from the cylindrical vessel containing the areometer before the contact was detached. The precise instant of contact and detachment was indicated by an electric signal. M. Duter thus demonstrated experimentally that the quantities of free austral and boreal magnetism were equal in the two portions (of contrary name) in the same plate. He sought to represent by an empiric formula, the results relative to forces of detachment for plates of different diameter. These forces depend simply on one specific coefficient variable with the nature of the steel and with the thickness.

THE influence on the animal organism of breathing pure oxygen gas of density corresponding to ordinary atmospheric pressure, has not hitherto been adequately determined. The Royal Society of Göttingen, therefore, offer a prize for new researches on the subject, made both on homoiothermal, and, as far as possible, on poikilothermal animals; in these researches, while certain externally visible phenomena in the animal will have to be considered, special attention is desired to be given to the nature of the blood and the exchange of material (excretion of carbonic acid, and nature of urine). The oxygen used should be carefully freed from all foreign matters apt to occur in manufacture; while a limited (and perhaps hardly avoidable) admixture of atmospheric nitrogen would not compromise the results. In the mathematical class, the Göttingen society desires (and offers a prize for) new researches on the nature of the unpolarised light-ray, "fitted to bring the conceptions of natural light of any origin, near (in definiteness) to those which theory connects with the various kinds of polarised light." (For further particulars see the Society's *Nachrichten*, No. 26, 1877.)

HITHERTO water has been regarded as possessing a greater specific heat than any other body, with the exception of hydrogen. In a recent session of the Vienna Academy M. E. Lecher communicated the results of experiments showing that in this respect water alone is surpassed by various mixtures of methylic alcohol and water, which will accordingly take the second position in regard to hydrogen.

THE Report of the Berlin Academy of Sciences for September and October, which has just appeared, contains, among other papers, "Comparison of the Tidal Heights in the East Sea from 1846–1875," by H. Hagen; "Anatomy of the Appendicularia," by Prof. Virchow and H. Langerhaus; "Atomic Weight of Molybdenum," by Prof. Rammelsberg; "Movement of the Electricity in Submarine and Subterranean Telegraphic Wires," by Prof. Kirchhoff; and "Catalogue of the Fishes and Amphibia from Chinchoxo (Africa), presented to the Berlin Zoological Museum by the *Afrikanische Gesellschaft*," by Prof. Peters.

THE electromotive force produced by the flow of water through capillary tubes has lately been investigated both by M. Haga at Strassburg University, and by Mr. J. W. Clark at Heidelberg (*Pogg. Ann.*, No. 11, 1877). Both observers used a quadrant electrometer instead of a galvanometer (as in former experiments with diaphragms and capillary tubes) to measure the difference of potential. This difference, according to M. Haga, is proportional to the pressure, independent of the length of the tubes, dependent on the nature of the inner surface of the tubes, increases with the resistance of the water, and probably also with the temperature. Mr. Clark finds (1) that the narrower the tube the greater is the electromotive force when liquids are forced through. (2) In very narrow tubes the electromotive force is independent of the length; in wider tubes it decreases with the length. (3) If the inner tube-surface be coated with different substances, different electromotive forces are obtained, whose amounts entirely agree with Quincke's former results with regard to diaphragm currents. (4) The electromotive force decreases with the time; and this whether still water or flowing water occupy the tube between the experiments. If the tube be cleaned anew with sulphuric acid and distilled water, the original electromotive force is re-established. (5) The seat of the electromotive force is the limiting surface of the liquid and the solid tube-wall.

THE Russian newspaper published in Turkestan reports that the scientific explorations in the Semirechensk District were continued uninterruptedly during the year 1877. Special attention was bestowed upon the investigation of the line of coral reefs which remained from the prehistoric Central Asian Sea. This line extends from the Dalashik Mountains over the Tuluk Tau and Temirlik Tau, and further eastward as far as the frontier of the Kuldsha District. Large quantities of the finest corals and beds of fresh-water shells were found; marine shells were discovered only in small quantities. The silurian formation of these districts may now be considered as proved beyond doubt.

THE new ethnological museum opened at the Hôtel des Invalides, Paris, contains a collection of warriors belonging to several nations and tribes, civilised and uncivilised. These models have been executed in an artistic manner and give a clear idea of the variety of destructive agencies resorted to by mankind for warlike purposes.

We have received a useful little manual of dates, "Drury's Chronology at a Glance" (Hardwicke and Bogue), containing much well-packed information. In the next edition the author should omit all expression of opinion on events and men, and utilise the space for additional information.

In the January number of Petermann's *Mittheilungen*, Dr. Mohn describes in detail the results as to soundings and temperatures of the Norwegian North Sea Expedition of 1876. Dr. Oscar Drude has an important article on the geographical distribution of palms, and a detailed programme is given of the new expedition of Gerhard Rohlfs, to which we referred last week. A brief sketch is given of the ten-years' exploration in South America of Doctors Reiss and Stübel, some of the results of which have appeared at various times in *Globus* and elsewhere, but the full details of which will necessarily take some time to publish.

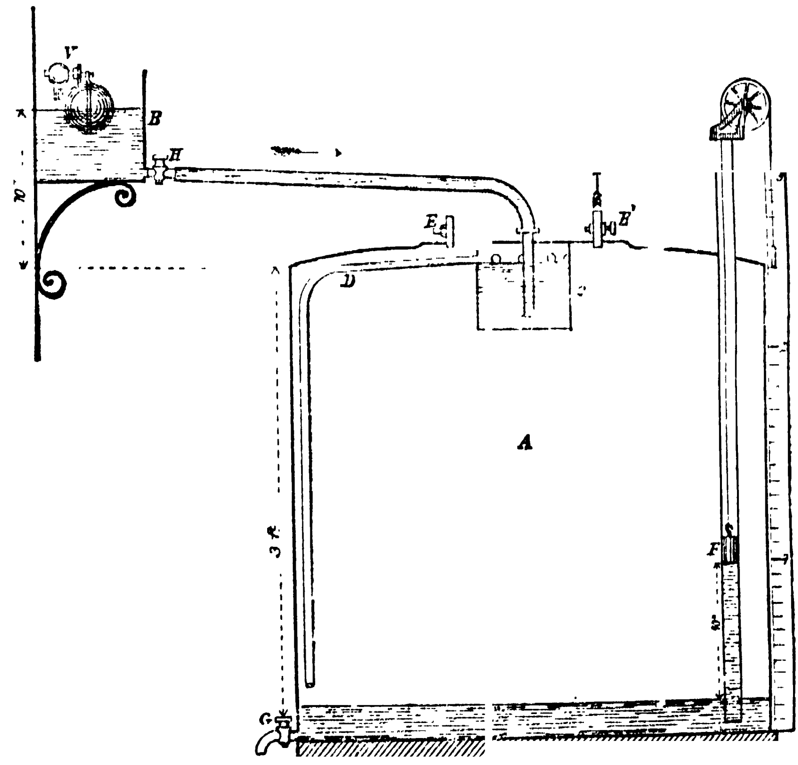
Dr. Radde, in a letter from Tiflis to Dr. Petermann, speaks of the brothers Brotheus, from Helsingfors and Wasa, who spen last summer in botanising in the Caucasus, taking back with them a varied collection of mosses and a rich herbarium of phanerogams.

The additions to the Zoological Society's Gardens during the past week include a Javan Chevrotain (*Tragulus javanicus*), a Stanleyan Chevrotain (*Tragulus stanleyanus*), from Java, presented by Mrs. Leslie Walker; a Grivet Monkey (*Cercopithecus griseo-viridis*) from North-East Africa, presented by Madame Patey; an Arabian Gazelle (*Gazella arabica*) from Arabia, presented by Mr. Mark Whyley; three Summer Ducks (*Aix sponsa*) from North America, presented by Lord Braybrooke; two Mandarin Ducks (*Aix galericulata*) from China, two White-bellied Storks (*Abdimia sphenorhyncha*) from West Africa, purchased; two Silky Cow Birds (*Molothrus bonariensis*) from South America, a Superb Tanager (*Calliste fastuosa*), two Violet Tanagers (*Euphonia violacea*) from Brazil, deposited.

NEW FORM OF GAS-HOLDER

Having found the necessity of a gas-holder which should yield a steady flow of gas and be under control from the lecture-room, at some distance from the only available spot where the gas-holder could be placed, I devised the following plan, which was carried out for me by Mr. Yeates, to whom I am indebted for one or two excellent suggestions. The arrangement is, I believe, novel, it is inexpensive, and it answers admirably; it may, therefore, be of convenience to put before some of your readers the following sketch, which needs but little explanation:—

A is a bell-shaped, gas-tight holder of galvanised iron or stout zinc. B is a water-supply cistern with adjustible ball-cock valve, in fact, an ordinary kitchen boiler supply-cistern, in connection with the water-main through V. C is a small reservoir fixed to the dome of the gas-holder; when filled, once for all, the water overflows into the holder; to avoid splashing it is better to convey a pipe, D, near to the bottom of the holder. The water-pipe from the cistern, B, passes air-tight into the gas-holder, and is furnished with a cock, H, to shut off the pressure when necessary. The pressure on the gas within the holder obviously depends on the difference of the water-level in the cisterns B and C. To give a brilliant lime-light some ten inches head of water is required. This corresponds to about 2 cwt. on the usual wedge-shaped gas-bag. To give a sensitive flame with a steatite gas-jet having an orifice the size of No. 19 wire, B W G (0·04 inch diameter), a pressure of some nine inches of water is required. The depth of the cistern, B, allows the ball-float a range of adjustment, and hence of gas-pressure, of some six inches.



E E′ are cocks for the entrance or exit of gas, and F is a float marking the quantity of gas in the holder.

When the gas has all been expelled from the holder it is full of water, and hence conveniently ready for refilling with gas. For this purpose the cock H is closed, and G partially turned on; the water escapes as the gas enters E. A delivery tube is carried from E′ to the lecture table, and can, of course, be used as an entrance as well as an exit pipe. After the holder is filled with gas, G is shut off and H and E′ are turned on. All is now ready for use, for as soon as the cock at the burner attached to the lantern or other arrangement in the lecture-room, is turned on, the gas is displaced from the holder by the entrance of a corresponding quantity of water from the cistern B. No weights are required to be taken on and off, an equable flow of gas is secured, the turning on of the gas-cock in the lecture-room puts the whole apparatus in action, and the employment of a single cylinder considerably diminishes the original cost of the gas-holder.

W. F. BARRETT

Royal College of Science, Dublin

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

BERLIN.—The Prussian budget contains provisions for four new professorships in the university, including two in medicine, one in philology, and one in botany. The appropriations for most of the laboratories, &c., in connection with the university have likewise been notably increased. The "Gewerbe-Akademie" is to receive an important addition in the shape of a department for the examination of iron, in which the physical and mechanical properties of the various sorts of Prussian iron—unwrought as well as manufactured—can be thoroughly tested, and officially approved. A similar institute, and the only one hitherto in Germany, has existed for a number of years at Munich, and has been of great value to the iron industry in South Germany. The lectures of Prof. Du Bois-Reymond on physiology have become so popular that no lecture-room in the university is of sufficient size to accommodate his numerous hearers.

INNSBRUCK.—The winter attendance at the university is 605, an increase of 27 on the past semester. The philosophical faculty includes 159, the medical 55, the legal 206, and the theological 185.

JENA.—The university is attended at present by 488 students, a diminution of 102 on the number of the past summer. Of the 219 in the philosophical faculty 64 study philosophy and history, 73 mathematics and natural sciences, 62 chemistry and pharmacy, and 20 political economy and agriculture. The attendance from foreign countries is but 35, and Jena is one of the few European universities where England is not represented.

SCIENTIFIC SERIALS

Annalen der Physik und Chemie, No. 11, 1877.—The residual charge of the Leyden jar, in its relation to the nature of the insulating substance, by M. von Oettingen.—On the electromotive force produced by flow of water in capillary tubes, by M. Haga.—On the same subject, by Mr. J. W. Clark.—On the connection between electromagnetic rotation and unipolar induction, by M. Edlund.—On Dr. Kerr's recently-found relation between light and electricity, by Mr. Mackenzie.—Calorimetric researches, by MM. Schulier and Wartha.—Apparatus for demonstrating the different heat-conducting powers of gases, by M. Kundt.—Observations by Adolf Rosencranz, on the influence of temperature on internal friction of liquids, by M. O. E. Meyer.—On a method of investigating the gliding friction of solid bodies, by MM. Warburg and v. Babo.—Determination of the velocity of sound by the method of coincidences, by M. Szathmari.—Velocity of wave motion in soft string, by M. Abt.—Studies on chemical volumes, by M. Ostwald.—On miargyrite, by M. Weisbach Lime, strontium, and baryta in the crystalline state, by M. Brügelmann.—On numerical determination of the constants of Weber's fundamental law, by M. Voigt.—On a simple experiment for subjectively showing the reversal of the coloured lines of flame-spectra, especially the sodium line, by M. Günther.—On completeness of exclusion of aqueous vapour from air-pumps, by M. Laspeyres.—On the applicability of fatty gases in blow-pipe operations, by M. Lohse.

Kosmos, July, 1877.—O. Caspari, on the philosophy of Darwinism.—Prof. Haeckel, in discussing Bathybius and the Monera, is very little inclined to give up the organic nature of Bathybius.—G. Jäger, on Heredity, part 2.—Carus Sterne (Dr. Krause) on the taming of the old by the young, discusses the influence of children from the Darwinian standpoint. He calls Bret Harte "probably the psychologist of deepest insight in our time."—Fräulein von Hellwald writes on the speechless primitive man.—Fritz Schultze on the origin of the culinary art.

August, 1877.—Mr. Darwin's biographical sketch of a little child is translated here.—Fritz Müller contributes observations on Brazilian butterflies on evolutional principles.—A. Dödel-Port writes on the colour and size of Alpine flowers—A. Lang, on Lamarck and Darwin, part 4, considers Lamarck's views on the relation of organic to inorganic nature.—Hugo Magnus treats on the development of the colour sense.

September, 1877.—Otto Caspari continues his discussion of the Darwinian philosophy, dealing with the problem of evil, the idea of individuation, the conditions of pleasure and disgust.—Prof. Jäger treats of colour and the colour-sense.—Prof. Krause discusses the origin of the legend of Iphis (Ovid, "Metam.," book ix.) with regard to its bearings on a morphological question.—Dr. A. Lang, in his fifth paper on Lamarck and Darwin, comes to Lamarck's theory of descent.—A comprehensive notice of Darwinian literature up to the present time is given by Dr. G. Seidlitz.

October, 1877.—Dr. B. Vetter, on design in nature.—H. Müller, on the variation in size of the coloured envelopes of flowers in relation to natural selection; a valuable paper.—Prof. Jäger, the origin of organs. Part III., locomotive organs.—Fritz Müller, on Brazilian butterflies, Part 2.—Dr. F. Weinland, on the language of primitive man.

Zeitschrift für wissenschaftliche Zoologie, vol. xxix., Part 4.—W. Schmankewitsch, on the influence of external conditions on the organisation of animals. This is a long and valuable paper, especially having to do with the influence of different degrees of concentration of salt water and varying temperatures on a number of Crustacea, as *Artemia salina*, Daphnia, Branchipus.—J. W. Spengel, on the reproduction of *Rhinoderma darwinii* (amphibian), a translation from the Spanish of X. Jimenez de la Espoda; a very remarkable case of a male brood-cavity.—B. Hatschek, on the embryonic history of the budding of *Pedicellina echinata* (polyzoan), forty-eight pages, three plates.—A. Wierzejski, on the crustacea parasitic on cephalopods, twenty-one pages, three plates.—H. von Ihering, contribution to the morphology of the kidneys of mollusca.

THE current number of the *Quarterly Journal of Microscopic Science* commences with a paper by Mr. C. S. Tomes, on the hinged teeth of the common pike, the existence of which, in other than the angler and one or two other fish, was unknown.—The Rev. Thomas Hinks has notes on the movements of the vibracula in *Caberea boryi*, and on the supposed *common* nervous system in the Polyzoa, in which the synchronous movement of the vibracula is shown to render the existence of a common nervous system almost essential.—Dr. A. M. Marshall describes the development of the cranial nerves in the chick, in continuation of his earlier papers in the *Philosophical Transactions* and the *Journal of Anatomy and Physiology*.—Prof. E van Beneden contributes to the history of the embryonic development of the Teleosteans, showing that the germ-layers do not proceed exclusively from the blastodisc: that extra blastodic cells are developed on the deuteroblastic globe, and that there is no segmentation cavity.—Mr. S. H. Vines writes on the homologies of the suspensor of the ovule, showing its unity with the seta and foot of mosses, liverworts, and vascular cryptogams.—Prof. Lankester describes the corpusculated nature of the red vascular fluid of the earthworm.—Dr. F. Darwin describes the contractile filaments of *Amanita* (*Agaricus*) *muscaria* and *Dipsacus sylvestris*.—The last paper is a short one by Mr. Dowdeswell, on atmospheric bacteria.

SOCIETIES AND ACADEMIES

LONDON

Mathematical Society, January 10.—Lord Rayleigh, F.R.S., president, in the chair.—Mr. F. B. W. Phillips was elected a member, and Mr. R. R. Webb was admitted into the Society.—The following papers were read:—Mr. J. Hammond, on the meaning of the differential symbol D^n, when n is fractional. (Prof. Cayley gave a few references to papers on the subject by [illegible], Schlœter, and others, and expressed his opinion that the matter had not yet been satisfactorily settled.)—Prof. Lloyd Tanner, on partial differential equations with several dependent variables.—Lord Rayleigh, on the relation between the functions of Laplace and Bessel (in § 783 of Thomson and Tait's "Natural Philosophy," a suggestion is made to examine the transition from formulæ dealing with Laplace's spherical functions to the corresponding formulæ proper to a plane). It is evident at once, from this point of view, that Bessel's functions are merely particular cases of Laplace's more general functions, but the fact seems to be very little known.—Mr. Ferrers, in his elementary treatise on Spherical Harmonics, makes no mention of Bessel's functions, and Mr. Todhunter, in his work on these functions, states expressly that Bessel's functions are not connected with the main subject of the book. The object of the present paper was to point out briefly the correspondence of some of the formulæ. The author showed that the Bessel's function of zero order (J_0) is the limiting form of Legendre's function, $P_n(\mu)$, when n is indefinitely great and μ ($= \cos\theta$) such that $n \sin\theta$ is finite, equal (say) to Z. This was proved by taking Murphy's series for P_n (Todhunter, § 23). In like manner Bessel's functions of higher order are limits of those Laplace's functions to which Todhunter gives the name of associated functions. A theorem was found for the general functions corresponding to the relation subsisting between three consecutive Bessel's functions $\left[\text{viz., } \tfrac{1}{2} Z\{J_{m-1}(z)+J_{m+1}(z)\} = m\,J_m(z)\right]$ (Prof. Cayley stated that the results obtained were very interesting).—Mr. S. Roberts gave some results bearing upon his paper read at the December meeting.—Prof. Cayley gave an expression for the surface of an ellipsoid communicated to him by Prof. Tait.—The Chairman, Professors Cayley, Tanner, and Mr. Webb spoke upon the subject.

Chemical Society, January 17.—Dr. Gilbert in the chair.—It was announced that a ballot for the election of Fellows would take place at the next meeting of the Society (February 7).—The following papers were read:—On the luminosity of benzol when burnt with non-luminous combustible gases, by E. Frankland and L. T. Thorne. After many unsuccessful attempts to burn benzol with a smokeless flame, the authors determined the luminosity of benzol vapour after dilution with hydrogen, carbonic oxide, and marsh-gas. These gases were passed through a benzoliser kept at a constant temperature and burnt in a fish-tail burner. The following results were obtained:—1 lb. avoirdupois of benzol gives, when burnt with hydrogen, the light yielded by 5·792 lbs. of spermaceti with carbonic oxide, that of 6·100 lbs. of spermaceti with marsh-gas, that of 7·7 lbs. of spermaceti. The authors point out that this difference is probably due in part to the different pyrometric thermal effects of the gaseous mixtures.—On the action of reducing agents on potassium permanganate, by F. Jones. Hydrogen reduces permanganate, sesquioxide of manganese being formed; ammonia produces in addition a nitrate, a nitrite, and free nitrogen; phosphine, arsine, and stibine give somewhat similar reactions; oxalic acid forms manganese sesquioxide, carbonic acid, and oxygen; strong solutions of permanganate and manganese chloride, when mixed, form sesquioxide of manganese, chlorine and oxygen being evolved.—On the action of sulphuric acid on copper, by Spencer Pickering. According to the author there are only two primary reactions, in one of which copper-sulphate, sulphurous acid, and water are the products, in the other subsulphide of copper, copper sulphate, and water are formed. The author has studied the action at various temperatures and has investigated the quantity of sulphuric acid actually used, the effect of an electric current, the action of impurities in the copper, the variations produced by diluting the acid, &c.—On the analysis of sugar, by G. Jones. The author proposes to estimate sucrose volumetrically by adding a 0·1 per cent. solution to a boiling decinormal solution of permanganate, acidulated with sulphuric acid, until the dirty-brown hydrated peroxide of manganese, which is at first formed, is reduced and dissolved.—On the decomposition products of quinine, by W. Ramsay and J. Dobbie. The authors oxidised quinine with permanganate and obtained a new acid, which they have identified with Dewar's dicarbopyridenic acid, and a red amorphous substance. The same acid was obtained by oxidising Marchand's quinetin.

Geological Society, December 19, 1877.—Prof. P. Martin Duncan, F.R.S., president, in the chair.—Messrs. William Fream, J. G. Hochstätter Godfrey, Herbert Goss, and John Fowke Lancelot Rolleston were elected Fellows of the Society.—The following communications were read:—On *Argillornis longipennis*, Owen, a large bird of flight, from the eocene clay of Sheppey, by Prof. Owen, C.B., F.R.S. In this paper the author described some remains of a large bird obtained by Mr. W. H. Shrubsole from the London clay of Sheppey (already referred to in NATURE), consisting of parts of fractured humeri belonging to the right and left sides of the same species or perhaps individual, and including the head of the bone, with portions of the upper and lower parts of the shaft. The texture of the shaft, the thinness of its bony wall, and the large size of the cavity recall the characters of the wing-bones of the large cretaceous pterodactyles. The author concluded that the bones obtained by Mr. Shrubsole furnished indications of a new genus and species of flying birds, for which he proposed the name of *Argillornis longipennis*. He regarded it as probably a long-winged natatorial bird, most nearly related to *Diomedea*, but considerably exceeding the Albatross (*D. exulans*) in size.—Contributions to the history of the deer of the European miocene and pliocene strata, by Prof. W. Boyd Dawkins, F.R.S. The author commenced by referring to the difficulties attending the study of the European miocene and pliocene deer, and indicated that the majority of the known antlers may be referred to two categories—an earlier or capreoline, and a later or axidine type. To the Capreoli he referred the following species:—*Dicroceros elegans*, Lart. (= *Prox furcatus*, Hemel), *Cervus dicranoceros*, Kaup (including *C. anoceros* and *trigonoceros*, Kaup), and *Cervus Matheronis*, Gerv. (= *C. bravardi*), from the miocene, and *Cervus australis*, Gerv., and *C. cusanus*, Croizet and Jobert, from the pliocene. To the Axeides belong *Cervus Perrieri*, Cr. and Job. (including *C. issiodorensis* and *pardinensis*, of the same authors), *C. etueriarum*, Cr. and Job. (= *C. rusoides*, Pom., and *C. perollensis* and *stylodus*, Brav.), *C. suttonensis*, sp. n., and *C. cylindroceros*, Brav. (including *C. gracilis*, Brav.), all from pliocene deposits. Besides these, the author noticed a species *insertæ sedis* under the name of *Cervus tetraceros*, Dawkins, which he regards as coming nearest to the Virginian deer, or cariacou (*Cariacus virginianus*). From the examination of the antlers of these species he indicates that in the middle miocene age the cervine antler consisted of a simply forked crown, whilst in the upper miocene it becomes more complex, although still small and erect, like that of the roe deer. In the pliocene it becomes larger and more complex, some forms, such as the *Cervus dicranios*, Nesti, being the most complicated of known antlers. The successive changes are analogous to those observed in the development of the antlers of the living deer with increase of age. In the miocene we have the zero of antler-development, and the capreoline type is older than any other. The nearest living analogue of the miocene deer is, according to the antler, the muntjak (*Styloceros*), now found only in the oriental region of Asia, along with the tapir, which also co-existed with *Cervus dicranoceros* in the miocene forests of Germany. The pliocene deer, again, are generally most nearly allied to the oriental axis and rusa deer, the only exception being *Cervus cusanus*, the antlers of which resemble those of the roe, an animal widely spread over Europe and Northern and Central Asia. The alliance of these pliocene deer with those now living in the Indian region is regarded by the author as a further proof of the warm climate of Europe in miocene times, confirmatory of the conclusions arrived at by Saporta from the study of the vegetation.—On the occurrence of *Branchipus* (or *Chirocephalus*) in a fossil state, associated with *Archæoniscus*, and with numerous insect-remains in the eocene freshwater limestone of Gurnet Bay, Isle of Wight, by Henry Woodward, F.R.S. The remains of crustacea and insects noticed in this paper were obtained by Mr. E. J. A'Court Smith from a thin bed of limestone belonging to the Osborne or St. Helen's series at Thorness and Gurnet Bay in the Isle of Wight. The collection is the result of about twenty years' work. The insect-remains comprise about fifty specimens of diptera, including wings of tipulidæ and culicidæ, and the pupa apparently of a gnat, one wing of a hemipterous insect, and a flattened homopterous insect identified by Mr. F. Smith with *Triecphora sanguinolenta*; two specimens referred to the lepidopterous genus *Lithosia*; only three orthoptera, one a *Gryllotalpa*, the other two belonging to a grasshopper; thirty-five hymenopterous wings, thirty-three of which are referred to ants of the genera *Myrmica*, *Formica*, and *Camponotus*; twenty-three examples of neuroptera referred to *Termes*, *Perla*, *Libellula*, *Agrion*, *Phryganea*, and *Hemerobius*; and twelve of coleoptera, including species of *Hydrophilus*, *Dyticus*, *Curculio*, *Anobium*, *Dorcus*, and *Staphylinus*. There were also two spiders. Several species of bivalved entomostraca have also been obtained from these deposits, and identified by Prof. Rupert Jones. Of the branchipod crustacean both sexes are fossilised and beautifully preserved, the males showing their large clasping antennæ, and the females their egg-pouches, with large and very distinct disc-like bodies representing the compressed eggs. Dr. F. Goldenberg notices a fossil from the coal-measures of Saarbrück which he regards as a branchipod, and describes and figures under the name of *Branchipusites* (rectè *Branchipodites*) *anthracinus*; but this interpretation of it is at least doubtful. The author names his species *Branchipodites vectensis.* The isopods accompanying this species are referred to the genus *Archæoniscus*, M.-Edw., and one of them is identified with the *Palæoniscus brongniarti* of Milne-Edwards. The other is probably a new species, perhaps nearly allied to the existing *Sphæroma serratum.*—The chronological value of the pleistocene deposits of Devon, by W. A. E. Ussher, F.G.S., of H.M. Geological Survey.

Entomological Society, January 16.—Anniversary Meeting.—Prof. J. O. Westwood, M.A., F.L.S., president, in the chair.—The following gentlemen were elected members of the council for the present year, viz.:—Henry Walter Bates, F.L.S., F.Z.S., G. C. Champion, W. L. Distant, J. W. Douglas, Rev. A. E. Eaton, M.A., E. A. Fitch, Ferdinand Grut, F.L.S., George Lewis, R. Meldola, F.R.A.S., F.C.S., Ewd. Saunders, F.L.S., Frederick Smith, J. Jenner Weir, F.L.S., Prof. J. O. Westwood, M.A., F.L.S.—Henry Walter Bates, F.L.S., F.Z.S., was elected president, and Messrs. J. J. Weir, treasurer, F. Grut, librarian, and R. Meldola and W. L. Distant, secretaries.—An address was read by the outgoing president, in which reference was made to many of the less accessible entomological memoirs of the past year. The address was ordered to be printed, and the meeting terminated with a vote of thanks to the officers of the Society.

PARIS
